INTRODUCTION

Blood via blood vessels delivers oxygen and nutrients to each tissue in the body and removes the waste produced by cells1,2, transports hormones, defends cells from external harmful substances, and maintains proper body temperature and homeostasis3. Therefore, a normal blood circulation is very important for maintenance of body function4.

The vascular endothelium is a layer of endothelial cells on the inner surface of the vascular layer5. It regulates fluidity and flow of blood and blood vessel tension via the synthesis and secretion of various kinds of substances having biological activity6. It also plays an important role in maintaining and controlling arterial blood vessel function and health by participating in platelet aggregation, thrombogenesis, and dissolution7. In other words, vascular endothelial cells primarily serve as an anatomical barrier to prevent blood circulation in the vessel wall, as well as to control blood vessel tension, partially control cell growth in the blood vessel wall, and regulate extracellular matrix deposition8. These cells are also involved in blood vessel protection from substances and cells, blood clotting in response to partial injury and inflammation, and homeostasis of blood vessels by repair responses9.

Continued inflammatory stimuli (e.g., oxidative stress, inflammatory cytokines, exposure to pathogenic agents) cause endothelial dysfunction, with endothelial cells becoming overactive or chronically active10. In this condition, damage to the vascular endothelium leads to excessive inflammation, resulting in excessive secretion of soluble adhesion molecules such as intercellular adhesion molecule (ICAM)-1, vascular cell adhesion molecule (VCAM)-1, e-selectin, and p-selectin from endothelial cells11. Oxidized cholesterol accumulates in the injured area, forming a plaque, and the inner wall of the blood vessel swells up, resulting in narrowing of the blood vessels and decreased blood circulation12.

Nitric oxide (NO), which plays a key role in maintaining endothelial homeostasis, is produced by endothelial nitric oxide synthase (eNOS) from the amino acid L-arginine in endothelial cells12. A typical function of NO is vasodilation13. The NO produced diffuses into the smooth...
Increased blood circulation by ginseng berry extract

**METHODS**

**Preparation of ginseng berry extract**

Raw ginseng berries were harvested from Hongcheon, Gangwon-do, South Korea, and the seeds were separated and removed. Ginseng berries were dried and refluixed with 100% distilled water and concentrated under reduced pressure at 45°C (the patent number 10-2015-0101209).

**Cell culture**

Human umbilical vein endothelial cells (HUVECs) and smooth muscle cells (A7r5) were both purchased from ATCC (Manassas, VA, USA). HUVECs were cultured in complete microvascular endothelial cell growth medium (EGM-2, Lonza Walkersville, Inc.), in humidified 5% CO₂ incubator at 37°C. A7r5 cells were cultured in complete medium (DMEM, Hyclone, GE Healthcare Life Sciences, South Logan, Utah, USA), in humidified 5% CO₂ incubator at 37°C.

**A7r5 and HUVEC co-culture**

Co-culture plates, SPLINsertTM Hanging plates were purchased from SPL (SPL Life Sciences, Pochun, Gyeonggi-do, South Korea). A7r5 cells were seeded at a density of 1 × 10⁵ cells per well in complete DMEM, and HUVECs were seeded at a density of 5 × 10⁴ cells per case in complete EGM-2. Cassettes with HUVECs were placed on each well and incubated in humidified 5% CO₂ incubator at 37°C.

**Cell viability**

HUVECs were seeded at a density of 1 × 10⁴ cells per well in a 96-well plate. Cells were incubated for 24 h with EGM-2, in humidified 5% CO₂ incubator at 37°C. After 24 h, the medium was removed and cells were washed with 1× DPBS (Hyclone). Fresh medium was added and ginseng berry extract at various concentrations (0, 15, 63, 250, and 500 µg/ml) was added. TNF-α (10 ng/ml) was added after 30 min and the cells were incubated in humidified 5% CO₂ incubator at 37°C. A Cell counting Kit-8 (Dojindo, Rockville, MD, USA) was used to determine the viability of HUVECs. CCK-8 solution (10 µl) was added in each well and incubated for 4 h in humidified 5% CO₂ incubator at 37°C. The absorbance was measured at 450 nm with a plate reader (Varioskan Lux, Thermofisher).

**Total RNA extraction and cDNA synthesis**

HUVECs were seeded at a density of 2 × 10⁵ cells per well and incubated for 24 h. Culture medium without FBS was added, and ginseng berry extract at various concentrations (20, 100, and 500 µg/ml) was added. TNF-α (10 ng/ml) was added to each group (except normal cell group) and incubated for 24 h. Cells were washed with 1× DPBS and treated with easy-BLUETM (1 ml) of the Total RNA Extraction Kit (Intron Biotechnology, Sungnam, Gyeonggi-do, South Korea). Cell lysates were collected, 200 µl of chloroform was added, and centrifuged at 10,000 ×g

(4°C, 10 min). Supernatants were collected, iso-propanol (500 µl) was added, and the mixture was kept for standing for 10 min at room temperature. The mixed solution was centrifuged at 7,500 ×g (4°C, 10 min), and the supernatants were discarded. Pellets were washed with 75% ethanol and centrifuged at 7,500 ×g (4°C, 5 min) twice. Pellets were dissolved with distilled water and treated with DEPC. Extraction of total RNA from A7r5 cells, which were co-cultured with HUVECs, was performed following the same procedure.

cDNA synthesis was performed with Power cDNA Synthesis Kit (Intron Biotechnology), according to the manual in the kit. Total RNA (1 µg) was used to synthesis cDNA, which was used to perform reverse transcription-polymerase chain reaction.

Intracellular nitric oxide production in HUVECs

HUVECs were seeded at a density of 2 × 104 cells per well in a 96-well black plate (SPL Life Sciences, Pochun, Gyeonggi-do, South Korea) and incubated in humidified 5% CO₂ incubator at 37°C. The culture medium was changed to FBS-free culture medium after 24 h, and ginseng berry extract at various concentrations (20, 100, and 500 µg/ml) was added to each well. TNF-α (10 ng/ml) was added after 30 min. Detection of intracellular NO was performed according to the kit, OxiSelectTM Intracellular Nitric Oxide (NO) Assay Kit (Cell Biolabs, San Diego, CA, USA) manual and fluorescence was measured with a fluorometric plate reader at 480 nm/530 nm.

cGMP quantification in A7r5 cells

A colorimetric cGMP ELISA Kit (Cell Biolabs) was used to determine the cGMP level in A7r5 smooth muscle cells. A7r5 cells were co-cultured with HUVECs and the samples were treated with or without TNF-α for 24 h in humidified 5% CO₂ incubator at 37°C. Cells were lysed and the cGMP level was determined in the lysates following the kit manual. At the end of the experiment, the absorbance was read at 450 nm using a plate reader.

Reverse transcription-polymerase chain reaction

Primers for HUVECs, β-actin, eNOS, ET-1, VCAM-1, ICAM-1, e-selectin, and p-selectin mRNA specific primers were synthesized and purchased from Macrogen (Seoul, South Korea). Primers for A7r5, GAPDH, VCAM-1, ICAM-3, e-selectin, and p-selectin were also synthesized and purchased from Macrogen (Table 1). Maxime PCR PreMix Kit (i-Taq) from Intron were used to perform PCR amplification. PCR products were loaded on 1% agarose gel to perform electrophoresis.

Subject characteristics and ginseng berry extract administration

In this study, 30 males (over 20 years of age) were included and divided into the following groups: Ginseng berry extract group (n=15; age, 34.73 ± 6.97 years; height, 172.3 ± 7.20 cm; weight, 73.33 ± 12.19 kg) and placebo group (n=15; age, 35.07 ± 10.25 years; height, 170.79 ± 9.19 cm; weight, 65.43 ± 14.67 kg). Two subjects in the placebo group voluntarily discontinued after 1 week of initiating the administration of ginseng berry extract and were excluded from the study. Thus, 28 patients orally took ginseng berry extract for 4 weeks, and ginseng berry extract distributed to the subjects completed...

RESULTS

Effects of ginseng berry extract on HUVEC viability

No cytotoxicity or adverse effects were observed in HUVECs even after treatment with the highest concentration of the ginseng berry extract (500 µg/ml; Figure 1). Since no cytotoxicity was observed at up to 500 µg/ml, we used the extract at a concentration up to 100 µg/ml in subsequent experiments.

Ginseng berry extract induces eNOS expression, which increases intracellular NO levels in HUVECs

TNF-α-induced cells showed downregulated eNOS expression and decreased NO production compared to normal cells. Treatment with the ginseng berry extract recovered the expression of eNOS and thereby the production NO. This result confirms that the ginseng berry extract affects the production of NO (Figure 2).

Ginseng berry extract regulates adhesion molecules through the NO-cGMP pathway in A7r5 muscle cells

HUVECs and A7r5 cells were co-cultured. Treatment with TNF-α decreased cGMP level, which was recovered by the ginseng berry extract in a dose-dependent manner. This result indicates that the ginseng berry extract has a significant effect on the NO-cGMP pathway.

The expression of the adhesion molecules VCAM-1, ICAM-1, e-selectin, and p-selectin increases in endothelial cells in response to excessive diet or stress. The results show that the expression of adhesion molecules increased in TNF-α-induced A7r5 cells and was reduced in cells treated with the ginseng berry extract (Figure 3).

Ginseng berry extract reduces TNF-α-induced adhesion molecule and ET-1 expression in HUVECs

The increased expression of adhesion molecules and ET-1 in TNF-α-induced HUVECs was decreased by treatment with the ginseng berry extract (Figure 4).

Blood circulation changes following the intake of ginseng berry extract

This study confirmed the relaxation of smooth muscle cells by the ginseng berry extract through in vitro experiments and clinical trials. There was no significant difference in age and physical characteristics among the participants in this study. In addition, there was no significant difference between the groups in blood circulation factors (RPWV, LPWV, RABPI, LABPI) at baseline ($p>0.05$). There was no interaction effect among RPWV, LPWV, and LABPI in the ginseng berry extract supplement group, but RABPI decreased in the ginseng berry extract supplement group and significantly increased in the placebo group ($p=0.016$; Table 1).

DISCUSSION

TNF-α decreases eNOS expression and intracellular NO level and markedly increases the expression of adhesion molecules and ET-1 in endothelial cells and muscle cells, resulting in endothelium dysfunction. The results showed that these abnormalities prevented endothelium dysfunction. Many ginsenosides in ginseng berry, including ginsenoside Re, are reported to have effect on penile erection in vivo studies. Erectile dysfunction is also associated with blood circulation and muscle contraction and relaxation. The problem of blood circulation is caused by endothelial dysfunction. Endothelial dysfunction has been reported to result from a reduction in NO level, which is also referred to as impaired vasodilation. The decrease in NO synthesis is due to a decrease in the expression of eNOS, a deficiency in substrate or cofactor required for eNOS activity, a change in cell signal transduction, impaired eNOS activation, and reactive oxygen species (ROS). As expected, the ginseng berry extract first increased the expression of eNOS and decreased the expression of ET-1 in endothelial cells. Increased expression of eNOS in endothelial cells eventually leads to NO production, which leads to the expression of cGMP in smooth muscle cells. Increased expression of cGMP causes smooth muscle cell relaxation and ultimately induces vasodi-
lution. In addition, expression of VCAM-1, ICAM-1, p-selectin, and e-selectin increased by high-fat diet was reduced by ginseng berry extract, resulting in smooth muscle cell relaxation. It is known that ET-1 is strongly expressed in obese conditions in which muscle cells shrink to interfere with blood flow; however, the mechanism is not clear (Figure 5).

A decrease in blood pressure and PWV levels was observed after ingesting ginseng berry extract for a certain period of time. Increasing the diameter of the blood vessel or decreasing the thickness of the vessel wall should occur to confirm PWV reduction. In vitro experiments using vascular endothelial cells and smooth muscle cells showed that ginseng berry relaxed muscles. When the muscles relax, the thickness of the vessel wall decreases and the blood vessels expand. Based on the results of our in vitro experiments and clinical trials, we found that the ginseng berry extract helps to improve blood circulation.

CONCLUSION

This study confirmed the effect of ginseng berry on blood circulation. Because of the difficulty in elucidating the clinical outcome, we constructed an in vitro system with two different cell lines. The change in the NO-cGMP pathway induced by ginseng berry extract was confirmed. Moreover, ginseng berry extract also decreased the expression of cell adhesion molecules causing inflammation in the blood vessel. As a result, this study suggests that the intake of ginseng berry extract improves blood circulation and therefore, ginseng berry extract intake would be helpful for people having problems with blood vessel function.
