Objective. To explore the effect of the case management mode combined with enhanced recovery after surgery (ERAS) in elderly patients with hip fracture.

Methods. A total of 102 elderly hip fracture patients admitted to our hospital from June 2018 to December 2019 were selected. The patients with hip fracture were divided into the control group (n = 51) and the observation group (n = 51) by the random number table method. The control group adopts the conventional nursing mode, and the observation group adopts the case management mode combined with ERAS. The bed activity time, hospitalization time, total hospitalization expenses, and the satisfaction of patients were observed. The numeric rating scale (NRS) was used to assess the patient’s pain before treatment and at 1, 3, and 5 days after treatment. The Harris score was used to assess the patient’s joint motor function before treatment and at the 8th week after treatment. The perioperative complications of the two groups were compared.

Result. After treatment, the observation group was better than the control group in terms of out of bed activity time, hospitalization time, total hospitalization expenses, and the satisfaction of patients (P < 0.05). Before treatment, there was no significant difference in NRS scores between the two groups (P > 0.05). Before treatment, there was no significant difference in NRS scores between the two groups (P > 0.05). After treatment, the NRS scores of the two groups were lower than before treatment, and on days 1, 3, and 5 after treatment, the NRS scores of the observation group were lower than those of the control group (P < 0.05). Before treatment, there was no difference in the Harris score between the two groups (P > 0.05). At the 8th week after treatment, the Harris scores of the two groups were higher than those before treatment, and the Harris scores of the observation group were higher than those of the control group (P < 0.05). The total incidence of perioperative complications in the observation group (4/51) was lower than that in the control group (13/51) (P < 0.05). Conclusion. The application of the case management mode combined with ERAS nursing in elderly patients with hip fracture can improve the clinical symptoms of patients, improve the therapeutic effect, and reduce the occurrence of complications, which is worthy of clinical application.

1. Introduction

Hip fracture often occurs in elderly patients; the main reason is that the elderly are mostly combined with osteoporosis, which is easy to fall and cause hip fracture. The disease has many complications and a poor prognosis, which seriously endangers the safety and health of the elderly, and it is often accompanied by symptoms such as pain and swelling [1]. Due to the limitation of the patient’s lower limbs activities, requiring prolonged bed, plus the elderly having other basic diseases, the patients often have venous thromboembolism (VTE), pressure ulcers, and other serious complications, which seriously affect the patient’s quality of life. Conventional nursing has a poor rehabilitation effect on patients, and nursing measures for patients need to be strengthened [2, 3]. Therefore, it is extremely important to nurse patients with hip fracture.

The case management mode first appeared in the early 20th century, and it was adopted by nursing and social work professions. The case management mode is a patient-centered approach that combines various fields of medical profession to provide targeted and personalized nursing...
measures [4]. Case management is a collaborative process of assessing, planning, implementing, coordinating, monitoring, and evaluating selected treatments and services. The program meets the health needs of patients by communicating with patients and coordinating available resources; thereby, the case management mode can effectively reduce medical expenses, promote high-quality, cost-effective medical outcomes, and improve the quality of care [5]. The case management mode has played an essential role in breast cancer, diabetes, liver cirrhosis, and other diseases [6].

The concept of enhanced recovery after surgery (ERAS) was first proposed by Kehlet. It is a medical mode based on evidence-based medicine and provides professional nursing and guidance for the whole perioperative period through the cooperation of medical staff from various disciplines [7]. It can promote the recovery of the patient’s body function, reduce bad psychology, improve compliance, save hospitalization costs, and accelerate the recovery of patients [8]. It is reasonable, rapid, and comprehensive, thereby, reducing stress response during the perioperative period and serious complications caused by long-term bed rest and can provide patients with the highest quality medical services [9].

The purpose of this study was to explore the application effect of the case management mode combined with ERAS in elderly patients with hip fracture. Specific reports are as follows.

2. Subjects and Methods

2.1. Subjects. The study selected 102 elderly patients with hip fracture admitted to our hospital from June 2018 to December 2019. Classification of hip fracture: femoral neck fractures, intertrochanteric fractures, and subtrochanteric fractures. Causes of hip fracture are falling from the bed, falling, and sudden twisting of lower limbs. Inclusion criteria: conforming the indications of hip fracture in the “Guidelines for adult hip fracture” [10], the hip fracture was confirmed by CT and MRI, no history of hip surgery, case data were complete, all patients were able to cooperate with nursing intervention, and all subjects signed informed consent forms. Exclusion criteria: combined with VTE, unable to perform functional exercises and severe organ disorders or old fractures. The patients with hip fracture were randomly divided into the control group (n = 51) and observation group (n = 51). In the observation group, there were 20 males and 31 females, with an average age of 75.89 ± 2.56 years, ranging from 61 to 86 years old. Education level: 19 cases of junior middle school or below, 18 cases of senior high school, and 14 cases of junior college or above. In the control group, there were 22 males and 29 females, with an average age of 76.75 ± 2.61 years, ranging from 63 to 89 years old. Education level: 20 cases of junior middle school or below, 19 cases of senior high school, and 12 cases of junior college or above. There were no significant differences in gender, age, education level, and other general data between the two groups (P > 0.05).

2.2. Methods

2.2.1. The Control Group Adopted the Conventional Nursing Mode. Including demonstration, the nursing operation of the fracture site, guided of functional exercises, informed the causes and preventive measures of fracture complications and other related knowledge, implemented psychological counseling and health science popularization, and instructed patients to take regular care and follow-up by telephone.

2.2.2. The Observation Group Adopted the Case Management Mode Combined with ERAS. The case management mode: established a case management team and provided professional training for team members; set up personal files in the case management system of the hospital, mainly including personal basic information, disease types, treatment plans, and follow-up rehabilitation, and organized a case management team to analyze and discuss the patient case information and formulated appropriate nursing plans; follow-up: before discharge, formulated rehabilitation plans after assessing the patient’s physical condition; and professionals paid regular return visits, timely understood the patients’ recovery status, improved rehabilitation plans, guided patients rehabilitation exercise, and urged them to regular review. The ERAS: ERAS intervention team was formed before treatment to formulate a nursing plan based on the actual situation of the patient, actively communicated with the patient, assisted the patient to become familiar with the ward environment, and explained the care precautions in the care of hip fracture and instructed patients to understand the relevant knowledge of hip fracture, including preoperative education, postoperative guidance, minimally invasive surgery, and early functional exercises. Patients were treated with complications prevention treatment and guided patients to get out of bed and carry out appropriate exercise training. The specific measures are given in Table 1.

2.3. Observation Index. The time for field activities after treatment, hospitalization time, total hospitalization expenses, and patient satisfaction score (0–100 points) were observed. The study adopted the numeric rating scale (NRS) to assess the patients’ pain before treatment and at 1, 3, and 5 days after treatment (0 points means painless, 1–3 point for mild pain, 4–6 point for moderate pain, and 7–10 point for severe pain). The Harris score was used to assess the patients’ joint motor function before treatment and at the 8th week after treatment (total score was 100 points, the higher the score, the stronger joint motor function). At the same time, the study also observed the perioperative complications of the two groups of patients.

2.4. Statistical Analysis. Data were processed by SPSS 22.0. The quantitative data were expressed as (x ± s), and the t-test was used for comparison. The enumeration data were expressed as %. The χ² test was used for comparison. Differences were considered significant at P < 0.05.
Table 1: Checklist for achieving ERAS management goals for patients with hip fracture.

| Bed number | Name | Gender | Age | Admission number |
|------------|------|--------|-----|-----------------|

Fundamentals prevention: active exercise (ankle pump exercise), passive exercise (lower limb massage), lower limb elevation and warmth, turning over frequently, deep breathing exercise, avoiding lower limb puncture and infusion, and getting out of the bed as soon as possible if the condition permits. Upon admission to the hospital, patients with hip fracture should wear stretch socks on both lower limbs as instructed by the doctor, including during the traction period, during operation, and after surgery. Quadriceps training and straight leg elevation training: 20–30 times/group and 3–5 groups/d, based on the patient’s tolerance. Knee flexion training: take the supine position, slowly flex the knee 45°, hold the hip 25° for 5 seconds, then slowly straighten, 10 times/group, and 1–2 groups/d, from passive flexion to active flexion excessive flexion. The responsible nurse on the day before the operation will check and record preoperative condition and basic information, and the postoperative will be recorded by the responsible nurse on the day. Research completion: yes, “✓”, no, “×” and indicate the reason.
3. Results

3.1. The Condition after Treatment of the Two Groups. After treatment, the observation group was better than the control group in terms of out of bed activity time, hospitalization time, total hospitalization expenses, and the satisfaction of patients \( (P < 0.05) \), as shown in Figure 1.

3.2. The NRS Score of the Two Groups. Before treatment, there was no significant difference in NRS scores between the two groups \( (P > 0.05) \). After treatment, the NRS scores of the two groups were lower than before treatment, and on days 1, 3, and 5 after treatment, the NRS scores of the observation group were lower than those of the control group \( (P < 0.05) \), as shown in Figure 2.

3.3. The Harris Score of the Two Groups. Before treatment, there was no difference in the Harris score between the two groups \( (P > 0.05) \). At the 8th week after treatment, the Harris scores of the two groups were higher than those before treatment, and the Harris scores of the observation group were higher than those of the control group \( (P < 0.05) \), as shown in Figure 3.

3.4. The Perioperative Complications of the Two Groups. The total incidence of perioperative complications in the observation group \( (4/51) \) was lower than that in the control group \( (13/51) \) \( (P < 0.05) \), as shown in Figure 4.

4. Discussion

With the growth of age, the various functions of the elderly body decline, the perception ability is weakened, and the movement response is slow, resulting in hip fracture becoming a common disease of the elderly. Hip fracture is mostly caused by osteoporosis in elderly patients, falling or being hit, and patients have symptoms such as lower limb pain, swelling, and limited mobility, which seriously affect the quality of life \[11\]. Patients with severe hip fracture need surgical treatment, which causes large surgical trauma, long postoperative recovery time, need to be in bed for a long time, and reduce activities; it will usually prone to serious complications such as bedsores, lung infections, and VTE and even life-threatening, which brings a heavy burden to patients, families, and society \[12, 13\]. Therefore, it is extremely important to care for elderly patients with hip fracture. With many years of rich nursing experience in our hospital, combined with the clinical characteristics of elderly hip fracture patients, our treatment achieved good results, after the case management mode combined with ERAS is applied to elderly hip fracture.

Case management mode is a cooperative, systematic, and flexible disease management mode. Through the evaluation of patients’ conditions, effective communication, coordination, and reasonable allocation of resources, professional medical staff provide patients with integrated and personalized nursing services, so as to effectively improve the quality of care for patients \[14\]. The case management mode will follow up the medical care from the patient’s hospital admission to discharge, from the ward to the home, and give them care and help in every detail. By discussing the rehabilitation and care plan with the patient, this mode jointly assumes the responsibility of implementing rehabilitation plans for patients, including organizing case talks, evaluating patients’ needs, formulating medical care plans, conducting psychological counseling, and follow-up after discharge, so as to provide holistic and continuous services for patients. After the application of the case management mode, patients can not only receive individualized high-quality nursing services but also get psychological comfort, which is conducive to the rapid return to society of patients after treatment \[15\]. ERAS adopts a series of optimized measures to enhance perioperative care, thereby reducing traumatic stress and accelerating the recovery of patients. It has been widely used in the management of gastrointestinal surgery, thoracic surgery, orthopedics, and other diseases. ERAS follows the principle of “people-oriented,” with the concept of promoting the rehabilitation of patients, improving living standards, implementing a series of comprehensive nursing measures, optimizing nursing intervention plans, and improving the quality of nursing \[16\]. ERAS can effectively improve the physiological function of patient, prevent stress stimulation, improve psychological condition, and reduce economic burden. It has the characteristics of continuity, rapidity, professionalism, and comprehensiveness, which can provide more comfortable nursing content \[17\]. ERAS includes popularizing joint movement by strengthening the knowledge of hip fracture care for patients and their families before surgery, ensuring patients in good condition during surgery, urging patients to exercise as soon as possible after surgery, formulating scientific and high-quality rehabilitation plan, and accelerating patient recovery after surgery \[18\]. In the intervention process of the case management mode combined with ERAS, medical staff implement multimodal analgesia care for patients, self-controlled analgesia through the use of pain-relieving pump, and follow the doctor’s instructions to give patients intravenous and oral analgesics, thereby reducing the pain of patients. In this study, our doctor found that the observation group was better than the control group in terms of out of bed activity time, hospitalization time, total hospitalization expenses, and the satisfaction of patients. After treatment, the NRS scores and Harris scores of the two groups were improved, and on the 1, 3, and 5 days after treatment, the observation group had lower NRS scores and higher Harris scores. These results indicated that the case management mode combined with ERAS can improve the clinical symptoms of patients and improve the therapeutic effect.

The results of this study showed that compared with the control group, the observation group had a lower risk of complications, and the incidence was only \( (4/51) \). The reasons are analyzed as follows. In clinical practice, the conventional nursing mode is usually performed for
patients with hip fracture, which has a certain nursing effect, but its intervention items are relatively simple, unable to provide patients with all aspects of nursing services, and fail to achieve the desired nursing effect. The professional medical staff of the case management mode, through the establishment of the case management team, the establishment of patients’ personal files, and regular return visits after discharge and other channels, the nursing management, tracking, and recording of the patient’s operation, before discharge, and after discharge are carried out; it can timely understand the patient’s rehabilitation situation, supervise the patient’s rehabilitation exercise, and provide patients with individuality and dynamics rehabilitation plan to reduce the incidence of patient complications [19, 20]. In addition, ERAS implements comprehensive interventions for patients with hip fracture. In the nursing process of ERAS, measures such as preoperative health education, basic prevention of VTE, functional exercise, fasting, and nondrinking can effectively relieve the tension of patients, increase the patient’s understanding of fracture-related knowledge, and reduce adverse stress reaction. Postoperative measures such as wearing elastic stockings and using anticoagulant drugs can prevent VTE in patients with hip fracture, and urinary system infections can be prevented by placing a drainage tube at the surgical site. Medical staff instruct patients to perform rehabilitation training in the postoperative such as knee bend training, lower limb massage, posture care, and standing out of bed that can enhance the body function of patients. At the same time, effective pain management is given to patients after surgery, which is conducive to improving the pain tolerance of patients and alleviating pain sensation. Medical staff assist patients with hip fracture in diet
management and exercise exercises and implement scientific education; this can enhance the self-care ability of patients, supervise the patient to take the initiative to take care of the fracture site, thereby, improving the quality of life of patients, promoting patients to recover early, and reducing the occurrence of pneumonia, infection, pressure ulcers, VTE, delirium, and other complications.

ERAS optimizes the entire perioperative nursing, including strengthening preoperative education, maintaining the optimal physiological state of patients during surgery, and formulating scientific rehabilitation plans for patients after surgery. The case management mode combined with ERAS has the advantages of pertinence and individualization, which can effectively reduce the complications of patients with hip fracture [21, 22].

5. Conclusion

In summary, the application of the case management mode combined with ERAS in elderly patients with hip fracture can improve the clinical symptoms and the therapeutic efficacy and reduce the incidence of complications, worthy of clinical application. In addition, there are still shortcomings in this study, such as small sample size and short observation time. It is necessary to increase the sample size and extend observation time in the future to provide evidence for clinical treatment.
