Optimization Design of Thermoelectric Power Generation System of Waste Heat Recovery

Introduction

Thermoelectric power generation device, as a typical power generation device, has the characteristic of no pollution, no noise, compact structure, and high power utilization efficiency. In order to improve the conversion efficiency of thermoelectric materials, a large number of studies have been conducted in previous years [1], especially in the past ten years [2]. In addition, researchers have worked on developing and optimizing the thermoelectric power generation system. However, the thermoelectric conversion efficiency is generally low in practice, which restricts its wide popular use in the field of energy conversion. Therefore, improving the thermoelectric power generation technology is very important [3].

In terms of heat dissipation design, plate-fin radiator is mostly chosen in TEG system to improve the heat dissipation efficiency. The heat dissipation design has a significant influence on the overall performance of the system. Therefore, the optimization of the heat dissipation design is very important. In the research of TEG heat dissipation design, it is not only necessary to carry out the heat dissipation design research of TEG system, but also to consider the optimization design research of the surrounding environment. The research shows that under the heat source environment, the heat dissipation capability can effectively reduce the condition of constant heat source temperature, enhancing the heat dissipation performance of the power generation unit.

In previous studies, which was used as the basis for the current optimization design research, the influence of various factors on heat dissipation performance was quantitatively analyzed by using software to deliver the best combination of heat dissipation parameters. The results showed that under the condition of constant heat flux density of 3W/cm², the optimal radiator configuration can be obtained by optimizing the radiator parameters. The optimal design parameters are as follows: the radiator height should be in the range of 8 mm to 90 mm, the radiator base thickness should be 8 mm, the spacing should be 3 mm, and the fin height of the machined radiator should be 8 mm to 90 mm.

Abstract: Considering that many parameters with mutual influence are difficult to be considered comprehensively, they were involved in the optimization design. Based on the optimal design scheme, the thermoelectric module efficiency was determined, which represents the optimal working temperature of the thermoelectric module. The optimal design scheme, which can calculate the optimal design scheme quantitatively according to the heat source temperature, was proposed in this work. The optimal working temperature of the thermoelectric module was comprehensively considered in the design of the thermoelectric power generation system.
The differential equation of heat conduction is used to simulate the temperature distribution in thermoelectric element with Bi₂Te₃ as the base, and FLUENT software is used to simulate the thin heat dissipation, which is a common simulating calculation method. The rationality of the process and accuracy of the results have been fully demonstrated in previous studies [16–21]. Based on these, an optimal design scheme of the TEG system was calculated by means of coupling and iterative calculation in this paper, so as to provide guidance for the practical engineering application of TEG.

2 TEG System Modeling

2.1 Initial conditions and design objective

The environment temperature is 20 °C, and the heat flux density of waste heat is about 36 kW/m². The design objective is to achieve the best thermoelectric performance of the thermoelectric element considering the operating economy of the heat dissipation module.

2.2 System module

The overall structure of TEG is composed of the power generator module and the heat dissipation module, as shown in Figure 1. Heat dissipation module includes radiator and fan, among which, radiator is adopted with plate-fin structure, with the characteristics of uniform distribution and simple form, which is beneficial to industrial mass production and application. It is assumed that the thermal properties and heat flux density of each unit are the same when working, and it is regarded as a whole.

![Fig. 1. Structure diagram of the thermoelectric power generation system](image)

2.3 Specifications and parameters of generator module

The semiconductor material selected for thermoelectric element is ternary solid solution alloy with Bi₂Te₃ as the base; P-type composition is (70 % ~ 75 %) Sb₂Te₃ + (25 % ~ 30 %) Bi₂Te₃ + P-type impurity, and N-type composition is (90 % ~ 93 %)Bi₂Te₃ + (7 % ~ 10 %) Bi₂Se₃ + N-type impurity. According to the actual structure parameters of the thermoelectric element, the established model size of the thermoelectric element is 40 mm x 40 mm. The relationship curve between the measured thermoelectric conversion efficiency and the temperature of the cold and hot ends is shown in Figure 2 [22].

![Fig. 2. The measured thermoelectric conversion efficiency curve of the thermoelectric element](image)

On the whole, as the cold end temperature drops from 80 °C to 30 °C, the thermoelectric conversion efficiency gradually increases. For a constant cold end temperature, as the hot end temperature increases, the thermoelectric conversion efficiency first increases, then tends to be steady, and finally decreases, and there is an optimal temperature range.

3 Thermoelectric Characteristics Analysis of Power Generation Module

Because the thermoelectric optimization value (ZT) and heat conductivity coefficient λ of the thermoelectric power generation element of semiconductor will change according to different cold and hot ends temperature, the actual thermoelectric conversion efficiency also changes accordingly. Under the condition of constant heat flux density of heat source, controlling the cold and hot ends in the optimal temperature range is one of the important ways to improve the thermoelectric conversion efficiency.

When the heat flow gets through the generator module, it involves the Seebeck effect, the Peltier effect, the Joule effect and the Thomson effect in the interior. If it is assumed that the material of the thermoelectric element is homogeneous, the heat is transmitted only along the direction of the current, and the contact resistance of the cold and hot ends is ignored, the differential equation of heat conduction in the thermoelectric element in the interior can be expressed as [17,19]:

\[
\lambda_n \frac{d^2T_n}{dx^2} - \beta_n \frac{dT_n}{dx} + \frac{R_n I^2}{d} = 0 \tag{1}
\]

\[
\lambda_p \frac{d^2T_p}{dx^2} - \beta_p \frac{dT_p}{dx} + \frac{R_p I^2}{d_p} = 0 \tag{2}
\]

Where \(\lambda_n\) and \(\lambda_p\) represent the heat conductivity coefficients, W/(m°C); \(T_n\) and \(T_p\) represent temperature; \(K\); \(\beta_n\) and \(\beta_p\) represent the Thomson coefficients; \(R_n\) and \(R_p\) represent resistance; \(\Omega\); \(d_n\) and \(d_p\) represent length, m; \(I\) represents the output current, A.

In addition, the following basic equations are also used [17]:
\[ a = \alpha_p - \alpha_n \]  
(3)

\[ U = \int_{T_1}^{T_2} \alpha(T) dT \]  
(4)

\[ R = R_n + R_p \]  
(5)

Where \( \alpha \) represents Seebeck coefficient, V/K; \( U \) represents the output voltage; \( V; T_b \) and \( T_i \) represent the temperature of hot and cold ends of the power generation film, K; \( R \) represents the total resistance of thermoelectric element, \( \Omega \).

If it is considered that half of the joule heat generated in the thermoelectric element is transferred to the hot end and the other half to the cold end, the heat flux density at the cold and hot ends can be approximately expressed as:

\[ q_h = \alpha T_h l + \lambda \frac{T_h - T_i}{d} - \frac{R}{2} I^2 \]  
(6)

\[ q_i = \alpha T_i l + \lambda \frac{T_h - T_i}{d} + \frac{R}{2} I^2 \]  
(7)

Where \( q_h \) and \( q_i \) represent the heat flux density of the hot and cold ends of the power generation film, W/m².

BAI Zhongkai and others selected the same type of thermoelectric element and obtained the relationship between the heat conductivity coefficient of the thermoelectric element and the temperature change by measuring the diffusion coefficient and the corresponding heat capacity [17, 18]:

\[ \lambda = A + B \times (T + 273) + C \times (T + 273)^2 \]  
(8)

Where \( A = 5.7631 \); \( B = -0.02416 \); \( C = 0.00003593 \); \( T \) represents the average temperature of the cold and hot ends of the power generation film, °C.

Combined with the measured thermoelectric conversion efficiency curve of the thermoelectric element (Figure 2), the curve of the relation between the cold and hot ends temperature and thermoelectric conversion efficiency of the thermoelectric element under the design condition is shown in Figure 3.

**Fig. 3.** The curve of the relation between the cold and hot ends temperature and efficiency of thermoelectric element under the design condition.

As can be seen, as the temperature of the cold end decreases, the temperature of the hot end also decreases, and the corresponding thermoelectric conversion efficiency gradually increases. When the temperature of the cold end drops to 50 °C, the efficiency reaches 5.16 %. When the temperature of the cold end continues to decrease, the growth of conversion efficiency slows down. If the temperature of the cold end further decreases, the additional increase in cooling fan power is larger. Based on the above considerations, the temperature of the cold end is suggested to be controlled at 50 °C. At this time, the electrical power density of TEG is 1.86 W/cm², and the heat flux density of the heat dissipation module is 34.14 W/cm².

### 4 Optimization Design of Heat Dissipation Module

Radiator is the key module of TEG, the reasonable design of radiator, not only with light weight and small volume, but also with better heat dissipation performance. The performance state is mainly related to the fin parameters, including fin height, fin spacing, base thickness and fin thickness, etc. Based on the heat flux density of 34.14 kW/m² and controlling the cold end temperature of the generator module at 50 °C, the iterative method commonly used in heat engineering calculation was proposed to be applied in heat dissipation design in this paper, to evaluate the influence of different fin height, fin spacing and base thickness on the heat dissipation capacity, and obtain the optimal radiator structure based on the minimum required wind speed.

#### 4.1 Mathematical model

The overall temperature of radiator is lower than 50 °C, so the influence of heat dissipation through radiation can be ignored, and the heat that flows through radiator sends out to the environment by the means of heat conduction and convection. It is a three-dimensional steady state and incompressible flow heat transfer process in the heat transfer unit, and the k-ε turbulence model is adopted to reflect turbulent flow on the convection side. The governing equations involved mainly include: thermal diffusion equation, mass conservation equation, momentum conservation equation, energy conservation equation and turbulence k-ε model [16, 20, 21].

The thermal diffusion equation is:

\[
\frac{\partial T}{\partial t} + \text{div}(\rho V) = 0
\]  
(9)

Where \( T \) represents temperature, K.

The mass conservation equation is:

\[
\frac{\partial \rho}{\partial t} + \text{div}(\rho V) = 0
\]  
(10)

Where \( \rho \) represents density, kg/cm³; \( t \) represents time, s; \( V \) represents the velocity vector, m/s; \( u, v \) and \( w \) respectively represent the components of the velocity vector in the x, y and z directions, m/s.

The momentum conservation equation is:

\[
\frac{\partial (\rho u)}{\partial t} + \text{div}(\rho u V) = \text{div}(\eta\text{grad}u) + F_x - \frac{\partial p}{\partial x}
\]  
(11)

\[
\frac{\partial (\rho v)}{\partial t} + \text{div}(\rho v V) = \text{div}(\eta\text{grad}v) + F_y - \frac{\partial p}{\partial y}
\]  
(12)
\[
\frac{\partial (\rho w)}{\partial t} + \text{div}(\rho w \mathbf{V}) = \text{div}(\eta \text{grad} w) + F_x - \frac{\partial p}{\partial x} \tag{13}
\]

Where \( \eta \) represents dynamic viscosity coefficient, \( \text{Pa} \cdot \text{s} \); \( F_x, F_y \) and \( F_z \) represent the components of the volume force in the \( x, y \) and \( z \) directions respectively, and \( p \) represents the pressure on the element body.

The energy conservation equation is:

\[
\frac{\partial (\rho T)}{\partial t} + \text{div}(\rho V T) = \text{div}(\frac{\lambda}{\text{cp}} \text{grad} T) + F_T \tag{14}
\]

Where \( c_p \) represents specific heat capacity, \( I/(\text{kg} \cdot \text{K}) \); \( F_T \) represents the heat transferred from mechanical work to fluid flow.

The governing equation of turbulent kinetic energy \( k \) is:

\[
\frac{\partial (\rho k)}{\partial t} + \frac{\partial (\rho u_i k)}{\partial x_i} = \frac{\partial}{\partial x_i} \left[ \left( \frac{\eta}{\sigma_k} \frac{\partial k}{\partial x_i} \right) + G_k - \rho \varepsilon \right] \tag{15}
\]

In formula (15):

\[
\eta_t = \rho C_\eta \frac{k^2}{\varepsilon} \tag{16}
\]

\[
G_k = 2\eta_t \left( \frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right) \frac{\partial u_i}{\partial x_j} \tag{17}
\]

Where \( \eta_t \) represents turbulent kinetic viscosity coefficient, \( \text{Pa} \cdot \text{s} \); \( G_k \) represents the generation rate of turbulence volume, \( \text{kg}/(\text{s} \cdot \text{m}) \).

The governing equation of dissipation rate \( \varepsilon \) is:

\[
\frac{\partial (\rho \varepsilon)}{\partial t} + \frac{\partial (\rho u_i \varepsilon)}{\partial x_i} = \frac{\partial}{\partial x_i} \left[ \left( \frac{\eta}{\sigma_\varepsilon} \frac{\partial \varepsilon}{\partial x_i} \right) + C_{1\varepsilon} G_k \frac{\varepsilon^2}{k} - C_{2\varepsilon} \rho \frac{\varepsilon^2}{k} \right] \tag{18}
\]

Where \( C_{1\varepsilon} = 1.44 \); \( C_{2\varepsilon} = 1.92 \); \( \sigma_k = 1 \); \( \sigma_\varepsilon = 1.3 \); \( C_\eta = 0.09 \).

### 4.2 Simulation calculation model

The calculation model of radiator was established by FLUENT software preprocessor gambit, tetrahedral shape was used in grid division, and a dense grid was arranged on the fin heat dissipation surface. The established structure model and divided grid are shown in Figure 4 and Figure 5.

In this work, grid-independent solution test was carried out on the fin area of the simulation calculation model. The model selection of No.1 and No.20 radiators in Table 1 was selected as the test object, and the heat transfer performance of the fin was compared when the size was 0.1 mm, 0.2 mm, 0.3 mm, 0.5 mm and 0.7 mm. The results showed that the heat flux will shift greatly when the grid size is larger than 0.3 mm. After considering the requirements of calculation accuracy and calculation speed, the grid size was determined as 0.2 mm.

The radiator is adopted with aluminum material, and the speed inlet condition is adopted. The wind direction is horizontal flow along the fin groove, the outlet is set as pressure outlet, and the heat dissipation surface is set as no slip speed mode. Heat flow flows in from the bottom of the base with a size of 34.14 kW/m² and an environment temperature of 20 °C. Steady-state standard turbulence k-\( \varepsilon \) model is adopted for calculation, SIMPLEC algorithm is selected for speed as well as pressure coupling, and the convergence standard is set by default.

![Fig. 4. Schematic diagram of the calculation structure](image)

![Fig. 5. Overall grid division of the heat dissipation module](image)

### 4.3 Radiator structure design

#### 4.3.1 Fin height and spacing optimization

The thickness of the fin shall be 2 mm, and the length and width of the base shall be 45 mm. Accordingly, under the condition that the base thickness is fixed as 10 mm, 20 kinds of radiators with different fin spacing and fin height are given in this paper, as shown in Table 1. The wind speed can be obtained by simulation calculation with the method described in Section 3.1, required by these 20 types of radiators when the average surface temperature under the base is slightly lower than 50 °C, and the result is shown in Figure 6.

| Table 1. Type of radiator (a) |
|-------------------------------|
| Element | \( D \) (mm) | \( N \) | \( S \) (mm) | \( H \) (mm) |
|--------|-----------|-----|------|------|
| 1-5    | 10        | 7   | 4    | 60/70/80/90/100 |
| 6-10   | 10        | 8   | 3.5  | 60/70/80/90/100 |
| 11-15  | 10        | 9   | 3    | 60/70/80/90/100 |
| 16-20  | 10        | 10  | 2.5  | 60/70/80/90/100 |
If the fin height and spacing parameters are fixed, and when the base is thin, the thermal resistance is small and the heat dissipation performance is improved, it is suitable to choose a smaller fin thickness value. From the figure, when the fin height and fin spacing are fixed as 90 mm and 3 mm respectively, the thickness of the base is suitable for 8 mm.

4.3.3 Iteration optimization

Under the condition that the base thickness is fixed as 8 mm, 8 kinds of radiators with different fin height and fin spacing are given in this paper, as shown in Table 3. With the same approach, the simulation results are shown in Figure 8.

| Table 3. Type of radiator (c) |
|-------------------------------|
| Element | $D$ (mm) | $N$ | $S$ (mm) | $H$ (mm) |
|---------|--------|----|--------|--------|
| 28-31   | 8      | 9  | 3      | 80/90/100/110 |
| 32-35   | 8      | 10 | 2.5    | 80/90/100/110 |

Fig. 8. The relationship between fin spacing/fin height and required wind speed

From the figure, when the base thickness is 8 mm, the optimal values of fin height and spacing are still 90 mm and 3 mm, and the iteration ends.

In terms of heat dissipation design, 35 different types of fin radiators are listed in Section 4.3. Under the design conditions, the required wind speed varies greatly, with the maximum value 1.9 times of the minimum value. It can be seen that the application of iterative method to find the best radiator structure is of great significance to reduce the mass volume of the device and improve the total efficiency of the system.

5 Conclusion

In this paper, the curve of the relation between the thermoelectric conversion efficiency of the generator module and the temperature at both ends is given, and the influence of various structural parameters on the heat dissipation performance is quantitatively analyzed. The specific conclusions are as follows:
1) Due to the influence of heat source and material characteristics, there is an optimal operating temperature when the thermoelectric element works. Under such a design condition, the temperature of the cold end of the generator module should be controlled at 50 °C. At this time, the efficiency reaches 5.16 % and the system output performance is the best.

2) When the fin thickness is 2 mm, the optimal values of base thickness, fin spacing and fin height are 8 mm, 3 mm and 90 mm respectively. At this time, when the average surface temperature of the base is slightly lower than 50 °C, the wind speed required is only 3.91 m/s.
