Abstract

In this paper we introduce a sublinear conditional operator with respect to a family of possibly nondominated probability measures in presence of multiple ordered default times. In this way we generalize the results of [5], where a reduced-form framework under model uncertainty for a single default time is developed. Moreover, we use this operator for the valuation of credit portfolio derivatives under model uncertainty.

Keywords: sublinear expectation, nondominated model, reduced-form framework, multiple default times

Mathematics Subject Classification (2020): 60G65, 91G40, 91G80

1 Introduction

In this paper we introduce a reduced-form framework for multiple default times under model uncertainty. To this purpose we define a sublinear conditional operator with respect to a family of probability measures possibly mutually singular to each other in presence of multiple ordered default times. In this way we extend the classical literature on credit risk in presence of multiple defaults, see for example [14], [15], [16] and [22] to the case of a setting where many different probability models can be taken into account.

Over the last years, several different approaches have been developed in order to establish such robust settings which are independent of the underlying probability distribution, see among others [1], [6], [11], [12], [13], [20], [21], [25], [26], [28], [29], [31] and [32]. However, the above results hold only on the canonical space endowed with the natural filtration. In credit risk and insurance modeling it is fundamental to model multiple random events occurring as a surprise, such as defaults in a network of financial institutions or the loss occurrences of a portfolio of policy holders. This requires to consider filtrations with a dependence structure. Such a problem is mentioned in [2] and solved for an initial enlarged filtration. In [5] they define a sublinear conditional operator with respect to a filtration which is progressively enlarged by one random time.

In this paper we extend the approach in [5] and define a sublinear conditional operator with respect to a filtration progressively enlarged by multiple ordered stopping times. Such an extension is connected to several additional technical challenges with respect to the construction in [5].

First, we cannot consider default times in all generality, but we need to focus on a family of ordered stopping times. In particular, we work in the setting of the top-down model for increasing default times introduced by Ehlers and Schönbucher in [14] as a generalization to the well known Cox model in [23]. More specifically, we start with a reference filtration $F$ and define a family of ordered stopping times $\tau_1, \ldots, \tau_N$, in a similar way as done in [14]. We then progressively enlarge $F$ with the filtrations $\mathbb{H}^n$ generated by $(1_{\{\tau_n \leq t\}})_{t \geq 0}$, $n = 1, \ldots, N$, and define $\mathbb{G}^{(n)} := F \lor \mathbb{H}^1 \lor \ldots \lor \mathbb{H}^n$, $n = 1, \ldots, N$. In our case, we construct $\tau_1 < \ldots < \tau_N$ in such a way that $\tilde{\tau}_n := \tau_n - \tau_{n-1}$ is

---

independent of $\mathcal{H}^{n-1}_t$ for any $n = 2, \ldots, N, t \geq 0$ conditionally on $\mathcal{F}_\infty$. In particular, the intensities are driven by $\mathcal{F}$-adapted stochastic processes which may be used to model dependence structures driven by common risk factors and also contagion effects. We first address the problem of computing $\mathcal{G}^{(N)}$-conditional expectations of a given random variable under one given prior in terms of a sum of $\mathcal{F}$-conditional expectations depending on how many defaults have happened before time $t$. This is also a new contribution to the literature on ordered multiple default times in the classical case, i.e., in presence of only one probability measure. For an analogous result following the density approach for modeling successive default times, we refer to [15]. The main technical issue in our setting is to compute conditional expectations when a strictly positive number of defaults, but not all the $N$ defaults, have happened. Already under a fixed prior the results for multiple ordered default times are not a trivial extension of the ones in a single default setting.

We then use this representation to define the sublinear conditional operator $\tilde{\mathcal{E}}^N$ under model uncertainty with respect to the progressively enlarged filtration $\mathcal{G}^{(N)}$. As in [5], our definition makes use of the sublinear conditional operator introduced by Nutz and van Handel in [27] with respect to $\mathcal{F}$. To this purpose we assume that $\mathcal{F}$ is given by the canonical filtration. In particular, we show that our construction is consistent with the ones in [27] in presence of no default and in [5] for $N = 1$, respectively. The main technical challenge is to prove a weak dynamic programming principle for the operator as done in [5] for the single default setting, as it requires to exchange the order of integration between the operator and expectations under a given prior. This problem also appears in [5], however it becomes significantly more complex in the case when some defaults have already happened, but not all of them. In this situation we cannot any longer rely on the techniques used in [5] but have to come up with additional steps, see Lemma 5.3 and Proposition 5.7. We then use the conditional sublinear operator to evaluate credit portfolio derivatives under model uncertainty. In particular, we focus on the valuation of the so-called i-th to default contingent claims $\text{CCT}^{(i)}$, for $i = 1, \ldots, N$. This subject has been widely studied under one reference probability measure, see for example [3], [10], [14], [15], [17], [19], [30] and the survey in [18]. Especially, intensity models are often used in option pricing under credit risk, see e.g., references in [8], [9], [15], [14], [17], [19], and [24]. Here we extend these approaches to a robust framework, by using $\tilde{\mathcal{E}}^N$ to evaluate payoffs under a worst case scenario. In particular, for the i-th to default contingent claims we are able to derive sufficient conditions under which the strong tower property holds. As done in [5] for the single default case, we can also establish a relation between the sublinear conditional operator and the superhedging problem in a multiple default setting for a generic payment streams under given conditions.

The paper is organized as follows. In Section 2 we present the generalized Cox model for successive default times. In Section 3 we evaluate conditional expectations in presence of multiple ordered stopping times on a classical probability space. In Section 4 we provide a reduced-form setting under model uncertainty for multiple default times. In particular, we define the sublinear conditional operator $\tilde{\mathcal{E}}^N$ and analyze its properties. In Section 5 we derive the weak dynamic programming principle for the operator $\tilde{\mathcal{E}}^N$. In Section 6 we apply the operator to the valuation of credit portfolio derivatives. In Section 7 we briefly analyze superhedging for payment streams in a robust setting with multiple defaults.

2 Multiple ordered default times in the Cox model

Let $(\Omega, \mathcal{F}, P)$ be a probability space with $\mathcal{F} := \mathcal{B}(\Omega)$, equipped with a reference filtration $\mathcal{F} = (\mathcal{F}_t)_{t \geq 0}$. Moreover, we consider an additional probability space $(\tilde{\Omega}, \mathcal{B}(\tilde{\Omega}), \tilde{P})$. We then define the product probability space

$$(\tilde{\Omega}, \tilde{\mathcal{G}}, \tilde{P}) := (\Omega \times \tilde{\Omega}, \mathcal{B}(\Omega) \otimes \mathcal{B}(\tilde{\Omega}), P \otimes \tilde{P}). \quad (2.1)$$

We use the notation $\tilde{\omega} = (\omega, \tilde{\omega})$ for $\omega \in \Omega$ and $\tilde{\omega} \in \tilde{\Omega}$. For every function $X$ on $(\Omega, \mathcal{B}(\Omega))$ we denote its natural immersion into the product space by $X(\tilde{\omega}) := X(\omega)$ for all $\omega \in \Omega$, and similarly for functions on $(\tilde{\Omega}, \mathcal{B}(\tilde{\Omega}))$. Furthermore, for every sub-$\sigma$-algebra $\mathcal{A}$ of $\mathcal{B}(\Omega)$, its natural extension as a sub-$\sigma$-algebra of $\mathcal{G}$ on $(\tilde{\Omega}, \tilde{\mathcal{G}})$ is given by $\mathcal{A} \otimes \{0, \tilde{\Omega}\}$, and similarly for sub-$\sigma$-algebras of $\mathcal{B}(\tilde{\Omega})$. In the following, we construct on $(\tilde{\Omega}, \tilde{\mathcal{G}}, \tilde{P})$ an increasing sequence of $N$ random times $0 < \tau_1 < \ldots < \tau_N < \infty$, as done in [14], giving a generalization of the Cox model.
We work under the following assumption.

**Assumption 2.1.** 1. On $(\hat{\mathcal{O}}, \mathcal{B}(\hat{\mathcal{O}}))$ there are $N$ random variables $E_1, \ldots, E_N$ which are i.i.d. unit-exponentially distributed under $\hat{P}$.

2. On $(\hat{\mathcal{O}}, \mathcal{G})$ the random variables $E_1, \ldots, E_N$ are independent of $\mathcal{F}_\infty$ under $\hat{P}$.

Under Assumption 2.1 we now introduce the random times construction on $(\hat{\mathcal{O}}, \mathcal{G}, \hat{P})$, along with the associated enlarged filtrations.

**Definition 2.2.** Let Assumption 2.1 hold. For each $n = 1, \ldots, N$, iteratively proceed along the following steps:

1. Choose a non-negative $\mathcal{G}^{(n-1)}$-adapted process $\lambda^n$ such that $\int_0^t \lambda^n_s ds < \infty \hat{P}$-a.s. for all $t < \infty$ and $\int_0^\infty \lambda^n_s ds = \infty \hat{P}$-a.s. with $\mathcal{G}^{(0)} := \mathcal{F}$.

2. Define $\tau_n := \inf\{t > \tau_{n-1} : \int_{\tau_{n-1}}^t \lambda^n_s ds \geq E_n\}$ with $\tau_0 := 0$.

3. Define the process $H^n = (H^n_t)_{t \geq 0}$ by $H^n_t := 1_{\{\tau_n \leq t\}}$ for $t \geq 0$, and denote by $\mathbb{H}^n$ the filtration generated by $H^n$.

4. Define the enlarged filtration $\mathcal{G}^{(n)}$ by $\mathcal{G}^{(n)} := \mathcal{G}^{(n-1)} \vee \mathbb{H}^n$, again using the convention $\mathcal{G}^{(0)} := \mathcal{F}$.

**Remark 2.3.** Our construction slightly differs from the one given in Definition 4.2 of [14] in the following two points. First, we do not assume that the initial filtration $\mathcal{F}$ satisfies the usual hypothesis. Second, in [14], the enlarged filtration corresponding to the first $n$ random times is defined as the smallest filtration which contains $\mathcal{F}$, satisfies the usual hypothesis and makes $\tau_1, \ldots, \tau_n$ stopping times. Such a filtration is not equal to $\mathcal{G}^{(n)}$, as it can be shown that $\mathcal{G}^{(n)}$ is in general not right-continuous. However, the results of [14] that are useful for our purposes also hold when $\mathcal{F}$ does not satisfy the usual hypothesis and for our choice of the enlarged filtrations $\mathcal{G}^{(n)}$, $n = 1, \ldots, N$.

We here summarize some results proved in Proposition 4.3 in [14].

**Proposition 2.4.** The stopping times introduced in Definition 2.2 satisfy the following properties:

1. $\tau_0 < \tau_1 < \ldots < \tau_N < \infty \hat{P}$-a.s.

2. $\hat{P} \left( \tau_{n+1} > t | \mathcal{G}^{(n)}_t \right) = e^{-\int_{\tau_n}^t \lambda^n_s ds}$, $t \geq 0$.

3. $\tau_{n+1}$ avoids the $\mathcal{G}^{(n)}$-stopping times, i.e., for every $\mathcal{G}^{(n)}$-stopping time $\Theta$, $\hat{P}(\tau_{n+1} = \Theta) = 0$.

Note that $\hat{P} \left( \tau_{n+1} > t | \mathcal{G}^{(n)}_t \right) = \hat{P} \left( \tau_{n+1} > t | \mathcal{G}^{(n)}_t \right) = e^{-\int_{\tau_n}^t \lambda^n_s ds}$, $t \geq 0$.

We now give a construction of $N$ random times $0 < \tau_1 < \ldots < \tau_N < \infty$ as above. Consider the i.i.d. unit-exponentially distributed random variables $E_1, \ldots, E_N$ introduced in Assumption 2.1. Moreover, let $\lambda^1, \ldots, \lambda^N$ be $\mathcal{F}$-adapted non-negative processes such that for $n = 1, \ldots, N$ and $0 \leq t < \infty$ it holds

\[
\int_0^t \lambda^n_s ds < \infty, \quad \int_0^\infty \lambda^n_s ds = \infty. \tag{2.2}
\]

We now define for each $n = 1, \ldots, N$ the random variable $\tilde{\tau}_n$ by

\[
\tilde{\tau}_n = \inf \left\{ t > 0 : \int_0^t \lambda^n_s ds \geq E_n \right\} \tag{2.3}
\]

and the random variable $\tau_n$ by

\[
\tau_n = \sum_{k=1}^n \tilde{\tau}_k. \tag{2.4}
\]
By construction and by Assumption 2.1 we have that \( \tau_n = \tau_n - \tau_{n-1} \) is independent of \( \mathcal{H}_t^{n-1} \) given \( \mathcal{F}_\infty \), for any \( n = 2, \ldots, N \), \( t \geq 0 \).

We now show that the random times \( (\tau_n)_{n=1,\ldots,N} \) satisfy Definition 2.2. In particular, we want to prove that for all \( n = 1, \ldots, N \) there exists a \( \mathcal{G}^{(n-1)} \)-adapted process \( \lambda^n \) such that

\[
\tau_n = \inf \left\{ t > \tau_{n-1} : \int_{\tau_{n-1}}^t \lambda^n_s ds \geq E_n \right\},
\]

setting \( \tau_0 := 0 \). It is clear that \( \tau_1 = \tilde{\tau}_1 \), so that we first choose \( \lambda^1 := \tilde{\lambda}^1 \). For a general \( n = 2, \ldots, N \), define

\[
\lambda^n_t := 1_{\{t < \tau_{n-1}\}} \tilde{\lambda}^{n-1}_\tau + 1_{\{t \geq \tau_{n-1}\}} \tilde{\lambda}^n_{\tau - \tau_{n-1}}, \quad t \geq 0.
\]

The process \( \lambda^n \) defined in this way is clearly \( \mathcal{G}^{(n-1)} \)-adapted. Moreover, we have

\[
\tau_n = \sum_{k=1}^n \tilde{\tau}_k = \sum_{k=1}^{n-1} \tilde{\tau}_k + \tilde{\tau}_n
\]

\[
= \tau_{n-1} + \inf \left\{ t > 0 : \int_0^t \tilde{\lambda}^n_s ds \geq E_n \right\}
\]

\[
= \tau_{n-1} + \inf \left\{ t > 0 : \int_{\tau_{n-1}}^{\tau_{n-1} + t} \lambda^n_s ds \geq E_n \right\}
\]

\[
= \inf \left\{ s > \tau_{n-1} : \int_{\tau_{n-1}}^s \lambda^n_u du \geq E_n \right\}.
\]

In the rest of the paper, we use default times \( (\tau_i)_{1 \leq i \leq N} \) constructed as in (2.3) and (2.4) with corresponding filtrations \( \mathbb{H}^i, \mathcal{G}^{(i)} \) for \( i = 1, \ldots, N \), \( \mathcal{G}^{(0)} = \mathcal{F} \), as introduced in Definition 2.2.

Remark 2.5. With this construction it holds

\[ \mathcal{G} = \mathcal{G}^{(N)} = \mathcal{F}_\infty \otimes \sigma(E_1) \otimes \ldots \otimes \sigma(E_N) \]

\[ = \mathcal{F}_\infty \vee \mathcal{H}_\infty^1 \vee \ldots \vee \mathcal{H}_\infty^N \]

\[ = \mathcal{F}_\infty \vee \sigma(\tilde{\tau}_1) \vee \ldots \vee \sigma(\tilde{\tau}_N) \]

\[ = \mathcal{F}_\infty \vee \sigma(\tilde{\tau}_1) \vee \ldots \vee \sigma(\tilde{\tau}_N). \]

Moreover, on the event \( \{ \tau_1 \leq t \} \) we have

\[ \mathcal{F}_t \vee \sigma(E_1) = \mathcal{F}_t \vee \sigma(\tau_1), \quad t \geq 0. \quad (2.5) \]

This follows as

\[ \mathcal{F}_t \vee \sigma(E_1) \subseteq \mathcal{F}_t \vee \sigma(\tau_1), \quad t \geq 0 \]

because \( E_1 = \int_0^{\tau_1} \tilde{\lambda}^1_s ds \) and

\[ \mathcal{F}_t \vee \sigma(\tau_1) \subseteq \mathcal{F}_t \vee \sigma(E_1), \quad t \geq 0 \]

by the definition of \( \tau_1 \) in (2.3) and (2.4).

Finally, we introduce the notation \( \tau := (\tau_1, \ldots, \tau_N) \) and the convention \( \tau_0 := 0, \tau_{N+1} := +\infty \). Given an \( N \)-dimensional vector \( \mathbf{u} = (u_1, \ldots, u_N) \) we denote by \( \mathbf{u}_{(k)} \), for \( k \leq N \), the \( k \)-dimensional vector containing the first \( k \)-entries of \( \mathbf{u} \). Furthermore, for every \( P \in \mathcal{P} \) let \( \mathcal{G}^{(P)} := \mathcal{G} \cap \mathcal{N}^P_\infty \), where \( \mathcal{N}^P_\infty \) is the collection of sets which are \( (P, \mathcal{F}_\infty) \)-null. We define the set

\[ L^P_\mathcal{F}(\Omega) := \{ \tilde{X} | \tilde{X} : (\tilde{\Omega}, \mathcal{G}^{(P)}) \rightarrow (\mathbb{R}, \mathcal{B}(\mathbb{R})) \text{ measurable function such that } \mathbb{E}^P[|\tilde{X}|] < \infty \}. \quad (2.6) \]
3 General pricing results for successive defaults on a given probability space

In the setting outlined in Section 2 we now extend the sublinear conditional expectation of $E^\tilde{P}$ to the case of multiple defaults. To this purpose we need to express the conditional expectation of a random variable $Y \in L^1_p(\tilde{\Omega})$ with respect to $\mathcal{G}_t^{(N)}$ in terms of conditional expectations with respect to $\mathcal{F}_t$, for any $t \geq 0$. In a first step we split the conditional expectation $E^\tilde{P}[Y|\mathcal{G}_t^{(N)}]$ as

$$E^\tilde{P}[Y|\mathcal{G}_t^{(N)}] = E^\tilde{P}[1_{\{t < \tau\}} Y|\mathcal{G}_t^{(N)}] + \sum_{k=1}^{N-1} E^\tilde{P}[1_{\{\tau_k \leq t < \tau_{k+1}\}} Y|\mathcal{G}_t^{(N)}] + E^\tilde{P}[1_{\{\tau_N \leq t\}} Y|\mathcal{G}_t^{(N)}]$$

(3.1)

for any $t \geq 0$. We now analyze the terms on the right-hand side of (3.1). We start by the following lemma which is a generalization of Lemma 2.13 in [5] and which can also be seen as an extension of a result in Section 2.2.2 in [13].

**Lemma 3.1.** For any $\mathcal{G}_\infty^{(N)}$-measurable random variable $Y$ there exists a unique measurable function

$$\varphi : (\mathbb{R}_+^{N} \times \Omega, \mathcal{B}(\mathbb{R}_+^{N}) \otimes \mathcal{F}_\infty) \to (\mathbb{R}, \mathcal{B}(\mathbb{R}))$$

such that

$$Y(\omega, \tilde{\omega}) = \varphi(\tau_1(\omega, \tilde{\omega}), \ldots, \tau_N(\omega, \tilde{\omega}), \omega), \quad (\omega, \tilde{\omega}) \in \tilde{\Omega}.$$  

(3.2)

**Proof.** The result follows by the same arguments used in the proof of Lemma 2.13 in [5]. □

We now provide some preliminary lemmas.

**Lemma 3.2.** Let $Y \in L^1_p(\tilde{\Omega})$. Then

$$1_{\{\tau_k \leq t\}} E^\tilde{P}[Y|\mathcal{F}_t \vee \mathcal{H}_t^1 \vee \ldots \vee \mathcal{H}_t^k] = 1_{\{\tau_k \leq t\}} E^\tilde{P}[Y|\mathcal{F}_t \vee \sigma(E_1) \vee \ldots \vee \sigma(E_k)] \quad \tilde{P}\text{-a.s.}$$  

(3.3)

for any $k = 1, \ldots, N$ and $t \geq 0$.

**Proof.** We first first consider the case $k = 1$ to show the main arguments of the proof in a simpler setting. For any $t \geq 0$ we have

$$1_{\{\tau_1 \leq t\}} E^\tilde{P}[Y|\mathcal{F}_t \vee \mathcal{H}_t^1 \vee \ldots \vee \mathcal{H}_t^k] = 1_{\{\tau_1 \leq t\}} E^\tilde{P}[Y|\mathcal{F}_t \vee \sigma(E_1)]$$

$$= 1_{\{\tau_1 \leq t\}} E^\tilde{P}[Y|\mathcal{F}_t \vee \sigma(\tau_1)].$$

(3.4)

Here the first equality follows by a generalization of Corollary 5.1.2 in [7], and the second one by the definition of $\mathcal{H}_t^1$. This together with (2.25) proves equation (3.4). Let now $k = 2, \ldots, N - 1$. For any $t \geq 0$, we get

$$1_{\{\tau_k \leq t\}} E^\tilde{P}[Y|\mathcal{F}_t \vee \mathcal{H}_t^1 \vee \ldots \vee \mathcal{H}_t^k]$$

$$= 1_{\{\tau_k \leq t\}} E^\tilde{P}[Y|\mathcal{F}_t \vee \mathcal{H}_t^1 \vee \ldots \vee \mathcal{H}_t^{k-1} \vee \sigma(E_k)]$$

(3.5)

$$= 1_{\{\tau_k \leq t\}} E^\tilde{P}[Y(1_{\{\tau_{k-1} \leq t\}} + 1_{\{\tau_{k-1} > t\}})|\mathcal{F}_t \vee \mathcal{H}_t^1 \vee \ldots \vee \mathcal{H}_t^{k-1} \vee \sigma(E_k)]$$

$$= 1_{\{\tau_k \leq t\}} E^\tilde{P}[Y|\mathcal{F}_t \vee \mathcal{H}_t^1 \vee \ldots \vee \mathcal{H}_t^{k-1} \vee \sigma(E_k)]$$

$$= 1_{\{\tau_k \leq t\}} E^\tilde{P}[Y|\mathcal{F}_t \vee \mathcal{H}_t^1 \vee \ldots \vee \mathcal{H}_t^{k-2} \vee \sigma(E_k) \vee \mathcal{H}_t^{k-1}]$$

(3.6)

$$= 1_{\{\tau_k \leq t\}} E^\tilde{P}[Y|\mathcal{F}_t \vee \mathcal{H}_t^1 \vee \ldots \vee \mathcal{H}_t^{k-2} \vee \sigma(E_k) \vee \sigma(E_{k-1})]$$

(3.7)

Here (3.5) and (3.6) follow by the same arguments used to prove (3.4) applied to $\mathcal{F}_t \vee \mathcal{H}_t^1 \vee \ldots \vee \mathcal{H}_t^{k-1}$ on the event $\{\tau_k \leq t\}$ and to $\mathcal{F}_t \vee \mathcal{H}_t^1 \vee \ldots \vee \mathcal{H}_t^{k-2} \vee \sigma(E_k)$ on the event $\{\tau_{k-1} \leq t\}$, respectively. By recursively repeating the same procedure we get (3.7). □
Lemma 3.3. For any \( \psi : (\mathbb{R}^N \times \Omega, \mathcal{B}(\mathbb{R}^N) \otimes \mathcal{F}_\infty) \to (\mathbb{R}, \mathcal{B}(\mathbb{R})) \), \( t \geq 0 \) and \( k = 1, \ldots, N \), it holds

\[
1_{\{\tau_k \leq t\}} \mathbb{E}^\hat{\mu} \left[ \psi(\tau_{(k)}, \tilde{\tau}_{k+1}, \ldots, \tilde{\tau}_N, :)|F_t \vee \sigma(E_1) \vee \ldots \vee \sigma(E_k) \right] = 1_{\{\tau_k \leq t\}} \mathbb{E}^\hat{\mu} \left[ \psi(u_{(k)}, \tilde{\tau}_{k+1}, \ldots, \tilde{\tau}_N, :)|F_t \right] |_{u_{(k)} = \tau_{(k)}}.
\]

Equation (3.8) then follows by using a monotone class argument as in the proof of Lemma 2.15 in [5].

Proof. We use a monotone class argument. Let \( A \in \mathcal{F}_\infty \) and \( s_l, \tilde{s}_l > 0 \) for \( l = 1, \ldots, k \), \( j = k + 1, \ldots, N \). Then we get

\[
1_{\{\tau_k \leq t\}} \mathbb{E}^\hat{\mu} \left[ \prod_{l=1}^{k} 1_{\{\tau_l \leq s_l\}} \prod_{j=k+1}^{N} 1_{\{\tau_j \leq \tilde{s}_j\}} | F_t \vee \sigma(E_1) \vee \ldots \vee \sigma(E_k) \right]
\]

Equation (3.9) follows by Assumption 2.1. Equation (3.8) then follows by using a monotone class argument as in the proof of Lemma 2.15 in [5]. \( \square \)

Lemma 3.4. Let \( Y \in L^1_{\hat{\mu}}(\tilde{\Omega}) \). Then

\[
\mathbb{E}^{\hat{\mu}} \left[ 1_{\{\tau_k \leq t < \tau_{k+1}\}} Y | \mathcal{G}_t(k) \right] = 1_{\{\tau_k \leq t < \tau_{k+1}\}} \mathbb{E}^{\hat{\mu}} \left[ 1_{\{\tau_k \geq t \geq \tau_{k+1}\}} Y | \mathcal{G}_t(k) \right] / \mathbb{P}(\tau_{k+1} > \tau_0). \tag{3.10}
\]

for any \( t \geq 0 \) and \( k = 0, \ldots, N \).

Proof. We have

\[
\mathbb{E}^{\hat{\mu}} \left[ 1_{\{\tau_k \leq t < \tau_{k+1}\}} Y | \mathcal{G}_t(k) \right]
\]

Equation (3.11) then follows by using a monotone class argument as in the proof of Lemma 2.15 in [5].
For any $P$ and $W$ we are now able to provide the following proposition, that reduces the

\begin{equation}
\mathbb{E}^\tilde{P} \left[ 1_{\{\tau_k \leq \tau_{k+1} \}} Y | \mathcal{G}_t^{(k)} \right] = 1_{\{\tau_k \leq \tau_{k+1} \}} \mathbb{E}^\tilde{P} \left[ 1_{\{\tilde{\tau}_{k+1} > t - u_k \}} \varphi(u_k, \tilde{u}_k, \cdot) | \mathcal{F}_t \right] \big|_{u_k = \tau_k},
\end{equation}

(3.12)

Equation (3.11) follows from Lemma 5.1.2 (ii) in [7], and we get (3.12) because

\begin{equation}
\tilde{P} \left( \tau_t > t | \mathcal{G}_t^{(k)} \right) = 1 \text{ on } \{t < \tau_t - 1\}
\end{equation}

(3.14)

for $l = k + 1, \ldots, N$, respectively. By recursively applying these arguments we get (3.13).

\begin{remark}
In (3.13) we apply a slightly more general version of Lemma 5.1.2 (ii) in [7], since $Y$ is not $\mathcal{G}_k^{(l)}$-measurable for $l = k + 1, \ldots, N$ but $\mathcal{G}_t^{(N)}$-measurable. The proof of the result in [7] can be adapted without significant changes to our case.
\end{remark}

We are now able to provide the following proposition, that reduces the $\mathcal{G}^{(N)}$-conditional expectations in (3.1) to $\tilde{P}$-conditional expectations.

\begin{proposition}
Let $Y \in L^1_{\tilde{P}}(\tilde{\Omega})$. Then

\begin{equation}
\mathbb{E}^\tilde{P} \left[ 1_{\{\tau_k \leq \tau_{k+1} \}} Y | \mathcal{G}_t^{(N)} \right] = 1_{\{\tau_k \leq \tau_{k+1} \}} \mathbb{E}^\tilde{P} \left[ 1_{\{\tilde{\tau}_{k+1} > t - u_k \}} \varphi(u_k, \tilde{u}_k, \cdot) | \mathcal{F}_t \right] \big|_{u_k = \tau_k},
\end{equation}

(3.15)

\begin{equation}
\tilde{P} \text{-a.s. for any } t \geq 0 \text{ and } k = 1, \ldots, N, \text{ where } \varphi \text{ is the function introduced in Lemma 3.1, i.e.,}
\end{equation}

\begin{equation}
\varphi : (\mathbb{R}_+^N \times \Omega, \mathcal{B}(\mathbb{R}_+^N) \otimes \mathcal{F}_\infty) \to (\mathbb{R}, \mathcal{B}(\mathbb{R}))
\end{equation}

such that

\begin{equation}
Y(\omega, \tilde{\omega}) = \varphi(\tau_N(\omega), \tilde{\omega}, \omega), \quad (\omega, \tilde{\omega}) \in \tilde{\Omega},
\end{equation}

and $u_k = (u_{k,k+1}, \ldots, u_{k,N}) \in \mathbb{R}^{N-k}$ with $u_{k,l} := u_k + \sum_{m=k+1}^l \tilde{v}_m$ for $l = k + 1, \ldots, N$.

\begin{proof}
For any $t \geq 0$ and $k = 1, \ldots, N$ we get

\begin{equation}
\mathbb{E}^\tilde{P} \left[ 1_{\{\tau_k \leq \tau_{k+1} \}} Y | \mathcal{G}_t^{(N)} \right] = 1_{\{\tau_k \leq \tau_{k+1} \}} \mathbb{E}^\tilde{P} \left[ 1_{\{\tilde{\tau}_{k+1} > t - u_k \}} \varphi(u_k, \tilde{u}_k, \cdot) | \mathcal{F}_t \right] \big|_{u_k = \tau_k},
\end{equation}

(3.16)

(3.17)

(3.18)

where (3.15) follows directly from Lemma 3.1. Moreover, we use Lemma 3.2 to get (3.16), together with the fact that by Lemma 3.1 there exists a unique measurable function $\varphi : (\mathbb{R}_+^N \times \Omega, \mathcal{B}(\mathbb{R}_+^N) \otimes \mathcal{F}_\infty) \to (\mathbb{R}, \mathcal{B}(\mathbb{R}))$ such that

\begin{equation}
Y(\omega, \tilde{\omega}) = \varphi(\tau_N(\omega), \tilde{\omega}, \omega), \quad (\omega, \tilde{\omega}) \in \tilde{\Omega}.
\end{equation}

By applying Lemma 3.3 to the functions

\begin{equation}
\psi_1 : (\mathbb{R}_+^N \times \Omega, \mathcal{B}(\mathbb{R}_+^N) \otimes \mathcal{F}_\infty) \to (\mathbb{R}, \mathcal{B}(\mathbb{R}))
\end{equation}

\begin{equation}
\psi_2 : (\mathbb{R}_+^2 \times \Omega, \mathcal{B}(\mathbb{R}_+^2) \otimes \mathcal{F}_\infty) \to (\mathbb{R}, \mathcal{B}(\mathbb{R}))
\end{equation}

(7)
defined by

\[ \psi_1(\tau_{(k)}, \tilde{\tau}_{k+1}, ..., \tilde{\tau}_N, \omega) := 1_{\{\tilde{\tau}_{k+1} > t-\tau_k\}} \varphi \left( \tau_{(k)}, \tau_k + \tilde{\tau}_{k+1}, ..., \tau_k + \sum_{j=k+1}^{N} \tilde{\tau}_j, \omega \right) \]

and

\[ \psi_2(\tau_k, \tilde{\tau}_{k+1}, \omega) := 1_{\{\tilde{\tau}_{k+1} > t-\tau_k\}}. \]

we get (3.17). In addition, it holds

\[ \tilde{P}(\tilde{\tau}_{k+1} > t - u_k | \mathcal{F}_t) \bigg|_{u_k = \tau_k} = \tilde{P} \left( E_{k+1} > \int_0^{t-u_k} \tilde{\lambda}_s \, ds \bigg| \mathcal{F}_t \right) \bigg|_{u_k = \tau_k} \]

\[ = \tilde{P} \left( E_{k+1} > \int_0^{t-u_k} \tilde{\lambda}_s \, ds \bigg| \mathcal{F}_t \right) \bigg|_{u_k = \tau_k} = e^{-\int_0^{\tau_k} \tilde{\lambda}_s \, ds} \tilde{P}\text{-a.s.}, \tag{3.19} \]

because for any \( t \geq 0 \) we have that \( \int_0^{t-u_k} \tilde{\lambda}_s \, ds \) is measurable with respect to \( \mathcal{F}_t \) and \( E_{k+1} \) is independent of \( \mathcal{F}_t \) by Assumption 2.1. \( \square \)

Let \( \tilde{X} : (\tilde{\Omega}, \tilde{\mathcal{G}}) \to (\mathbb{R}, \mathcal{B}(\mathbb{R})) \) be a measurable function. Analogously to the setting of [5], and with a slight notational abuse, we introduce the notation

\[ \mathbb{E}^{\tilde{P}}[\tilde{X}](\omega) := \int_{\tilde{\Omega}} \tilde{X}(\omega, \tilde{\omega}) \tilde{P}(d\tilde{\omega}), \quad \omega \in \Omega. \tag{3.20} \]

When not needed, we do not make the dependence on \( \omega \) explicit.

**Theorem 3.7.** Let \( t \geq 0 \). If \( Y \in L^1_{\tilde{P}}(\tilde{\Omega}) \), then

\[ \mathbb{E}^{\tilde{P}} \left[ Y | \mathcal{G}_{t}^{(N)} \right] = 1_{\{t < \tau_{(1)}\}} e^{\int_0^t \tilde{\lambda}_s \, ds} \mathbb{E}^{\tilde{P}} \left[ 1_{\{t < \tau_{(1)}\}} Y \bigg| \mathcal{F}_t \right] \]

\[ + \sum_{k=1}^{N-1} 1_{\{\tau_k \leq t < \tau_{k+1}\}} e^{\int_{t-\tau_k}^{t} \tilde{\lambda}_s \, ds} \mathbb{E}^{\tilde{P}} \left[ 1_{\{t \geq \tau_{k+1} \}} \varphi(\mathbf{u}_{k}, \cdot) | \mathcal{F}_t \right] \bigg|_{u_k = \tau_k} + \frac{1_{\{\tau_{(N)} \leq t\}} \mathbb{E}^{\tilde{P}}[\varphi(\mathbf{u}_{(N)}, \cdot) | \mathcal{F}_t] |_{u_{(N)} = \tau}}{\tilde{P}\text{-a.s.}} \tag{3.21} \]

where \( \varphi \) is the function introduced in Lemma 3.1, i.e.,

\[ \varphi : (\mathbb{R}_+^N \times \Omega, \mathcal{B}(\mathbb{R}_+^N) \otimes \mathcal{F}_\infty) \to (\mathbb{R}, \mathcal{B}(\mathbb{R})) \tag{3.22} \]

such that

\[ Y(\omega, \tilde{\omega}) = \varphi(\tau_{(N)}(\omega, \tilde{\omega}), \omega), \tag{3.23} \]

and \( \mathbf{u}_k = (u_{k,1}, ..., u_{k,N}) \in \mathbb{R}^{N-k} \) with \( u_{k,l} := u_k + \sum_{m=k+1}^{N} \tilde{\tau}_m \) for \( k = 1, ..., N \).

**Proof.** Fix \( t \geq 0 \) and \( Y \in L^1_{\tilde{P}}(\tilde{\Omega}) \). By applying Lemma 3.1 to the case \( k = 0 \) and Proposition 3.6 to the other terms in (3.1), we get

\[ \mathbb{E}^{\tilde{P}} \left[ Y | \mathcal{G}_{t}^{(N)} \right] = 1_{\{t < \tau_{(1)}\}} e^{\int_0^t \tilde{\lambda}_s \, ds} \mathbb{E}^{\tilde{P}} \left[ 1_{\{t < \tau_{(1)}\}} Y | \mathcal{F}_t \right] \]

\[ + \sum_{k=1}^{N-1} 1_{\{\tau_k \leq t < \tau_{k+1}\}} e^{\int_{t-\tau_k}^{t} \tilde{\lambda}_s \, ds} \mathbb{E}^{\tilde{P}} \left[ 1_{\{t \geq \tau_{k+1} \}} \varphi(\mathbf{u}_{k}, \cdot) | \mathcal{F}_t \right] |_{u_k = \tau_k} + \frac{1_{\{\tau_{(N)} \leq t\}} \mathbb{E}^{\tilde{P}}[\varphi(\mathbf{u}_{(N)}, \cdot) | \mathcal{F}_t] |_{u_{(N)} = \tau}}{\tilde{P}\text{-a.s.}} \]

where \( \varphi \) is the function introduced in Lemma 3.1, i.e.,

\[ \varphi : (\mathbb{R}_+^N \times \Omega, \mathcal{B}(\mathbb{R}_+^N) \otimes \mathcal{F}_\infty) \to (\mathbb{R}, \mathcal{B}(\mathbb{R})) \]
such that

\[ Y(\omega, \hat{\omega}) = \varphi(\tau_{(N)}(\omega, \hat{\omega}), \omega), \]

and \( u_{\tilde{k}, k}^\tau = (u_{\tilde{k}, k+1}^\tau, \ldots, u_{\tilde{k}, k}^\tau) \in \mathbb{R}^{N-k} \) with \( u_{\tilde{k}, l}^\tau := u_k + \sum_{m=k+1}^{l} \tilde{r}_m \) for \( l = k+1, \ldots, N \).

By Lemma 2.12 in [5], for \( X \in L_1^P(\bar{\Omega}) \) and for any \( t \geq 0 \) we have

\[ \mathbb{E}^P[X|F_t] = \mathbb{E}^P[\mathbb{E}^P[X|F_t]] \quad \tilde{P}\text{-a.s.}, \tag{3.24} \]

where \( \mathbb{E}^P[X] \) is introduced in (3.20). Therefore, we get

\[ \mathbb{E}^P[1_{(t < \tau_1)} Y|F_t] = \mathbb{E}^P \left[ \mathbb{E}^P \left[ 1_{(t < \tau_1)} Y \right| F_t \right] \right] \quad \tilde{P}\text{-a.s.} \tag{3.25} \]

and

\[ \mathbb{E}^P \left[ 1_{(\tau_{k+1} > t - u_k)} \varphi(u_k, u_{\tilde{k}, \cdot})|F_t \right] \bigg|_{u_{\tilde{k}, k} = \tau_{(k)}} = \mathbb{E}^P \left[ \mathbb{E}^P \left[ 1_{(\tau_{k+1} > t - u_k)} \varphi(u_k, u_{\tilde{k}, \cdot}) \right| F_t \right] \bigg|_{u_{\tilde{k}, k} = \tau_{(k)}} \quad (3.26) \]

\( \tilde{P}\)-a.s. for every \( t \geq 0 \). Moreover, \( \mathbb{E}^P[\varphi(u_{(N), \cdot})|F_t]|_{u_{(N), \tau} = \tau} = \mathbb{E}^P[\varphi(u_{(N), \cdot})|F_t]|_{u_{(N), \tau} = \tau} \quad (3.27) \)

\( P \) a.s., for any \( t \geq 0 \). Putting together (3.24), (3.26) and (3.27) we finish the proof. \[ \square \]

4 Sublinear conditional operator for multiple default times

In this section we introduce a sublinear conditional operator with respect to a family of possibly nondominated probability measures, on a filtration enlarged with \( N \) stopping times. The definition of this operator is based on the construction of \( N \) ordered random times as in Section 2 and on the representation of the \( \mathbb{G}^{(N)} \)-conditional expectation in (3.24) from Theorem 3.7. Moreover, the following construction is a generalization of the definition of sublinear conditional operator under model uncertainty with respect to a filtration enlarged by one random time, as introduced in [5].

Let \( \Omega = D_0([0, \infty), \mathbb{R}) \) be the space of càdlàg functions \( \omega = (\omega_t)_{t \geq 0} \) in \( \mathbb{R} \) starting from zero, which is equipped with the metric induced by the Skorokhod topology. We consider the measurable space \( (\Omega, \mathcal{F}) \), where \( \mathcal{F} := \mathcal{B}(\Omega) \) is the Borel \( \sigma \)-algebra on \( \Omega \). The set of probability measures on \( (\Omega, \mathcal{F}) \) is given by \( \mathcal{P}(\Omega) \). We assume that \( \mathcal{P}(\Omega) \) is endowed with the topology of weak convergence. Furthermore, we denote by \( B := (B_t)_{t \geq 0} \) the canonical process, i.e., \( B_t(\omega) = \omega_t, t \geq 0 \), and its corresponding raw filtration by \( \mathcal{F} := (\mathcal{F}_t)_{t \geq 0} \) with \( \mathcal{F}_0 = \{\emptyset, \Omega\} \) and \( \mathcal{F}_\infty := \bigvee_{t \geq 0} \mathcal{F}_t = \mathcal{F} \). For every given \( P \in \mathcal{P}(\Omega) \) and \( t \geq 0 \), we define \( \mathcal{N}_t^P \) as the collection of sets which are \( (P, \mathcal{F}_t) \)-null, and consider the filtration \( \mathcal{F}^P := (\mathcal{F}_t^P)_{t \geq 0} \) defined by

\[ \mathcal{F}_t^P := \mathcal{F}_t \vee \mathcal{N}_t^P, \quad \mathcal{N}_t^P := \bigcap_{P \in \mathcal{P}(\Omega)} N_t^P. \tag{4.1} \]

For a given family of probability measures \( \mathcal{P} \) on \( \Omega \) we define the \( \sigma \)-algebra \( \mathcal{F}^P \) by

\[ \mathcal{F}^P := \mathcal{F} \vee \mathcal{N}_\infty^P, \quad \mathcal{N}_\infty^P := \bigcap_{P \in \mathcal{P}} N_\infty^P. \tag{4.2} \]

We follow the approach of [27] for defining sublinear expectations and introduce the following notation. Let \( \tau \) be a finite-valued \( \mathbb{F} \)-stopping time and \( \omega \in \Omega \). For every \( \hat{\omega} \in \Omega \), the concatenation process \( \omega \otimes \hat{\omega} := ((\omega \otimes \hat{\omega})_t)_{t \geq 0} \) of \( \omega, \hat{\omega} \) at \( \tau \) is given by

\[ (\omega \otimes \hat{\omega})_t := \omega_t 1_{(0, \tau(\omega))}(t) + (\omega_{(\tau)} + \hat{\omega}_{(t-\tau(\omega))}) 1_{(\tau(\omega), +\infty)}(t), \quad t \geq 0. \tag{4.3} \]

Furthermore, for every function \( X \) on \( \Omega \), define the function \( X^{\tau, \omega} \) on \( \Omega \) by

\[ X^{\tau, \omega}(\hat{\omega}) := X(\omega \otimes \hat{\omega}), \quad \hat{\omega} \in \Omega. \tag{4.4} \]
Remark 4.3. As a slight generalization to Proposition 2.4, it can be seen that for any \( n = 1, \ldots, N \) such that for \( n = 1, \ldots, N \) and \( 0 \leq t < \infty \) holds \( \tilde{F}_{\tilde{t}} \) holds \( \mathcal{P} \)-q.s. for all \( \tilde{P} \in \tilde{\mathcal{P}} \). Moreover, on \( (\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathcal{P}}) \) we consider non-negative \( \mathbb{F} \)-adapted processes \( \tilde{\lambda}^1, \ldots, \tilde{\lambda}^N \) such that for \( n = 1, \ldots, N \) and \( 0 \leq t < \infty \) holds \( \mathcal{P} \)-q.s. Furthermore, for each \( n = 1, \ldots, N \) the random times \( \tilde{\tau}_n \) and \( \tau_n \) on \( \tilde{\Omega} \) are defined as in (2.3) and (2.4) with associated filtrations \( \mathbb{H}^n \) and \( \mathbb{G}^{(n)} \) as in Definition 2.2.

Remark 4.3. As a slight generalization to Proposition 2.4 it can be seen that for any \( n = 0, \ldots, N - 1 \) the following properties hold:

- \( \tilde{\tau}_n := \tau_n - \tau_{n-1} \) is \( \mathcal{P} \)-q.s. independent of \( \mathcal{H}_t^{(n-1)} \) given \( \mathcal{F}_\infty \) for any \( t \geq 0 \) i.e., for each \( \tilde{P} \in \tilde{\mathcal{P}} \), \( \tilde{\tau}_n = \tau_n - \tau_{n-1} \) is independent of \( \mathcal{H}_t^{(n-1)} \) given \( \mathcal{F}_\infty \) for any \( t \geq 0 \) with respect to \( \tilde{P} \).
2. $\tau_{n+1}$ avoids $\mathcal{G}^{(n)}$-stopping times $\tilde{\mathcal{P}}$-q.s.

For $n = 1, \ldots, N$ we denote by $\mathcal{G}^{(n)}$ the corresponding universally completed filtration as in (4.11). Moreover, let $\mathcal{G}^P := \mathcal{G} \vee \mathcal{N}^\infty_\mathcal{P}$ with $\mathcal{N}^\infty_\mathcal{P}$ defined\(^1\) in (4.12). In addition, we define $L^0(\tilde{\Omega})$ as the space of all $\mathbb{R}$-valued $\mathcal{G}^P$-measurable functions, where we use the following convention. For every $\tilde{P} \in \mathcal{P}(\tilde{\Omega})$, we set $E^{\tilde{P}}[X] := E^{\tilde{P}}[X^+] - E^{\tilde{P}}[X^-]$ if $E^{\tilde{P}}[X^+]$ or $E^{\tilde{P}}[X^-]$ is finite and $E^{\tilde{P}}[X] := -\infty$ if $E^{\tilde{P}}[X^+] = E^{\tilde{P}}[X^-] = +\infty$. For each $\tilde{P} \in \mathcal{P}$, the set $L^0_{\tilde{P}}(\tilde{\Omega})$ is given by (2.6). Furthermore, we introduce the set

$$L^1(\tilde{\Omega}) := \{\tilde{X} : (\tilde{\Omega}, \mathcal{G}^P) \to (\mathbb{R}, \mathcal{B}(\mathbb{R})) \text{ measurable function such that } \tilde{E}(|\tilde{X}|) < \infty\},$$

where $\tilde{E}$ denotes the upper expectation associated to $\tilde{\mathcal{P}}$ defined as

$$\tilde{E}(\tilde{X}) := \sup_{\tilde{P} \in \mathcal{P}} \tilde{E}^{\tilde{P}}[\tilde{X}], \quad \tilde{X} \in L^0(\tilde{\Omega}).$$

We now use Theorem 3.7 to define the sublinear conditional operator $\tilde{E}^N$.

**Definition 4.4.** Let Assumption 4.1 hold for $\mathcal{P}$ and consider an upper semianalytic function $Y$ on $\tilde{\Omega}$ such that $Y \in L^1(\tilde{\Omega})$ or $Y$ is $\mathcal{G}^P$-measurable and non-negative. For $t \geq 0$ we define the following function

$$\tilde{E}^N_t(Y) := 1_{\{t < \tau_1\}} \tilde{E}_t \left( e^{\int_0^t \tilde{X} \text{d}E^{\tilde{P}}_t} \left[ 1_{\{t < \tau_1\}} Y \right] \right) + \sum_{k=1}^{N-1} 1_{\{\tau_k \leq t < \tau_{k+1}\}} \tilde{E}_t \left( e^{\int_{\tau_k}^t \tilde{X} \text{d}E^{\tilde{P}}_t} \left[ 1_{\{t - u_k < \tau_{k+1}\}} \varphi(u_k, u_{k+1}) \right] \right) \bigg|_{u_k = \tau(k)} + 1_{\{\tau_N \leq t\}} \tilde{E}_t(\varphi(u_{(N)})) \bigg|_{u_{(N)} = \tau(N)},$$

(4.11)

where $\varphi$ is the measurable function

$$\varphi : (\mathbb{R}_+^N \times \tilde{\Omega}, \mathcal{B}(\mathbb{R}_+^N) \otimes \mathcal{F}_\infty) \to (\mathbb{R}, \mathcal{B}(\mathbb{R}))$$

such that

$$Y(\omega, \tilde{\omega}) = \varphi(\tau_1(\omega, \tilde{\omega}), \ldots, \tau_N(\omega, \tilde{\omega}), \omega), \quad (\omega, \tilde{\omega}) \in \tilde{\Omega},$$

and $u_k^x$ is given in Theorem 3.7 and $(\varphi_t)_{t \geq 0}$ denotes the conditional sublinear operator introduced in Proposition 4.2.

**Remark 4.5.** Note that Theorem 3.7 also holds for $Y$ which is in $L^1(\tilde{\Omega})$ or $Y$ which is $\mathcal{G}^P$-measurable and non-negative. This follows as Lemma 3.1 can also be proved for a $\mathcal{G}^P$-measurable random variable, see also Remark 2.14 in [5]. In this case $\varphi : (\mathbb{R}_+^N \times \tilde{\Omega}, \mathcal{B}(\mathbb{R}_+^N) \otimes \mathcal{F}_\infty) \to (\mathbb{R}, \mathcal{B}(\mathbb{R}))$, which we use in (3.22) and (3.23).

We now recall Lemma 2.17 in [5] which lists some properties of upper semianalytic functions.

**Lemma 4.6.** Let $X, Y$ be two Polish spaces.

1. If $f : X \to Y$ is a Borel-measurable function and a set $A \subseteq X$ is analytic, then $f(A)$ is analytic. If a set $B \subseteq Y$ is analytic, then $f^{-1}(B)$ is analytic.

2. If $f_n : X \to \mathbb{R}, n \in \mathbb{N}$, is a sequence of upper semianalytic functions and $f_n \to f$, then $f$ is upper semianalytic.

3. If $f : X \to Y$ is a Borel-measurable function and $g : Y \to \mathbb{R}$ is upper semianalytic, then the composition $g \circ f$ is also upper semianalytic. If $f : X \to Y$ is a surjective Borel-measurable function and there is a function $g : Y \to \mathbb{R}$ such that $g \circ f$ is upper semianalytic, then $g$ is upper semianalytic.

\(^1\)Note that it is important to consider here the $\sigma$-algebra $\mathcal{G}^P$ and not $\mathcal{G}^\tilde{P} := \mathcal{G} \vee \mathcal{N}^\infty_\mathcal{P}$. For the same reason, the results in Section 3 are only stated for a $\mathcal{G}^P$-measurable random variable and not one which is measurable with respect to $\mathcal{G}^\tilde{P} := \mathcal{G} \vee \mathcal{N}^\infty_\mathcal{P}$.

11
4. If \( f, g : X \to \mathbb{R} \) are two upper semianalytic functions, then \( f + g \) is upper semianalytic.

5. If \( f : X \to \mathbb{R} \) is an upper semianalytic function, \( g : X \to \mathbb{R} \) is Borel-measurable such that \( g \geq 0 \), then the product \( f \cdot g \) is upper semianalytic.

6. If \( f : X \times Y \to \mathbb{R} \) is upper semianalytic and \( \kappa(dy;x) \) is a Borel-measurable stochastic kernel on \( Y \) given \( X \), then the function \( g : X \to \mathbb{R} \) defined by

\[
g(x) = \int f(x,y)\kappa(dy;x), \quad x \in X,
\]

is upper semianalytic.

**Proposition 4.7.** Let Assumption 4.4 hold for \( \mathcal{P} \) and consider an upper semianalytic function \( Y \) on \( \Omega \) such that \( Y \in L^1(\Omega) \) or \( Y \) is \( G_{\mathcal{P}} \)-measurable and non-negative. Then the sublinear conditional operator \( \mathcal{E}_t^N(Y) \) satisfies the consistency condition

\[
\hat{\mathcal{E}}_t^N(Y) = \text{ess sup}_P \mathbb{E}^P \left[ Y \big| \mathcal{G}_t^N \right] \quad \hat{\mathcal{P}}\text{-a.s. for all } \hat{\mathcal{P}} \in \mathcal{P},
\]

for any \( t \geq 0 \), where \( \hat{\mathcal{P}}(t; \hat{\mathcal{P}}) = \{ \hat{\mathcal{P}}' \in \mathcal{P} : \hat{\mathcal{P}}' = \hat{\mathcal{P}} \text{ on } \mathcal{G}_t^N \} \).

**Proof.** By the same arguments as in the proof of Lemma 2.18 in [5], \( e^{\int_0^t \hat{\lambda}_s^+ds} \mathbb{E}^\hat{\mathcal{P}} \left[ 1_{\{t < \tau_1\}} Y \right] \) is an upper semianalytic function on \( \Omega \) for any \( t \geq 0 \).

We now prove that

\[
e^{\int_0^t -\hat{\lambda}^-_s + ds} \mathbb{E}^\hat{\mathcal{P}} \left[ 1_{\{\tau_{k+1} > t - u_k\}} \varphi(u_k, \hat{u}_k^+, \cdot) \right]
\]

(4.13) is an upper semianalytic function on \( \Omega \) for \( k = 1, \ldots, N-1 \) and fixed \( u_k(\cdot) \), for every \( t \geq 0 \). Note that by Theorem 3.1 and Remark 4.5 there exists a function

\[
\hat{\varphi} : (\mathbb{R}_+^N \times \mathcal{B}(\mathbb{R}_+^N) \otimes \mathcal{F}_t^\mathcal{P}) \to (\mathbb{R}, \mathcal{B}(\mathbb{R}))
\]

such that

\[
Y(\omega, \hat{\omega}) = \varphi(\tau_N(\omega), \hat{\omega}, \omega) = \hat{\varphi}(\hat{\tau}(\hat{\omega}, \omega), \omega),
\]

with \( \tau_N = (\hat{\tau}_1, \ldots, \hat{\tau}_N) \). Therefore, we can rewrite (4.13) as

\[
e^{\int_0^t -\Delta_k u \hat{\lambda}_s^+ + ds} \mathbb{E}^\hat{\mathcal{P}} \left[ 1_{\{\tau_{k+1} > t - \sum_{i=1}^{k+1} u_i\}} \hat{\varphi}(\hat{u}_k(\cdot), \hat{\tau}_k(\cdot), \cdot) \right].
\]

where \( \hat{\tau}_k(\cdot) := (\hat{\tau}_k, \ldots, \hat{\tau}_N) \).

From now on we fix \( t \geq 0 \), \( k = 1, \ldots, N-1 \) and \( \hat{u}_k(\cdot) \). By point 5 of Lemma 4.6 it is enough to prove that \( \mathbb{E}^\hat{\mathcal{P}} \left[ 1_{\{\tau_{k+1} > t - \sum_{i=1}^{k+1} u_i\}} \hat{\varphi}(\hat{u}_k(\cdot), \hat{\tau}_k(\cdot), \cdot) \right] \) is an upper semianalytic function on \( \Omega \), as \( e^{\int_0^t -\hat{\lambda}^-_s + ds} \) is a non-negative Borel-measurable function.

Next, we show that \( Z := \mathbb{E}^\hat{\mathcal{P}} \left[ 1_{\{\tau_{k+1} > t - \sum_{i=1}^{k+1} u_i\}} \hat{\varphi}(\hat{u}_k(\cdot), \hat{\tau}_k(\cdot), \cdot) \right] \) is an upper semianalytic function on \( \Omega \times \hat{\Omega} \). Point 6 of Lemma 4.6 will then imply that (4.13) is an upper semianalytic function on \( \Omega \). As \( 1_{\{\tau_{k+1} > t - \sum_{i=1}^{k+1} u_i\}} \) is Borel-measurable on \( \Omega \times \hat{\Omega} \) and non-negative, it can be seen that \( Z \) is upper semianalytic applying again point 5 of Lemma 4.6. Therefore, it remains to show that for fixed \( k = 1, \ldots, N-1 \) and \( \hat{u}_k(\cdot) \), the function

\[
(\omega, \hat{\omega}) \mapsto \hat{\varphi}(\hat{u}_1, \ldots, \hat{u}_k, \hat{\tau}_k(\omega, \hat{\omega}), \ldots, \hat{\tau}_N(\omega, \hat{\omega}), \omega)
\]

is upper semianalytic. We first prove that the function \( g : \mathbb{R}_+^N \times \hat{\Omega} \to \mathbb{R} \) given by

\[
g(\hat{u}_l(\cdot), \omega) = \hat{\varphi}(\hat{u}_l(\cdot), \omega)
\]

is upper semianalytic.

To do so, define the function \( f : \Omega \times \hat{\Omega} \to \mathbb{R}_+^N \times \hat{\Omega} \) with \( f(\omega, \hat{\omega}) = (\hat{\tau}_1(\omega, \hat{\omega}), \ldots, \hat{\tau}_N(\omega, \hat{\omega}), \omega) \). Then \( f \) is surjective by the definition of \((\hat{\tau}_n)_{n=1}^N\). Note that \( Y(\omega, \hat{\omega}) = \hat{\varphi} \circ f(\omega, \hat{\omega}) = g \circ f(\omega, \hat{\omega}) \) is an
upper semianalytic function on $\Omega \times \tilde{\Omega}$, which implies by the second part of point 3 of Lemma 4.6 that the function $g$ is upper semianalytic on $\mathbb{R}_+^N \times \Omega$.

We now define the function $\tilde{f} : \mathbb{R}_+^k \times \Omega \times \tilde{\Omega} \to \mathbb{R}_+^N \times \Omega$ by

$$\tilde{f}(\tilde{u}(k), \omega, \tilde{\omega}) = (\tilde{u}(k), \tilde{T}_{(k+1, N)}(\omega, \tilde{\omega}), \omega),$$

which is a Borel-measurable function on $\mathbb{R}_+^k \times \Omega \times \tilde{\Omega}$. Then it holds

$$h(\tilde{u}(k), \omega, \tilde{\omega}) := g \circ \tilde{f}(\tilde{u}(k), \omega, \tilde{\omega}) = \tilde{\varphi}(\tilde{u}(k), \tilde{T}_{(k+1, N)}(\omega, \tilde{\omega}), \omega),$$

which is again upper semianalytic on $\mathbb{R}_+^k \times \tilde{\Omega} \times \tilde{\Omega}$ by the first part of point 3 of Lemma 4.6.

For fixed $\tilde{u}(k)$ define now $\tilde{\Psi}_{\tilde{u}(k)} : \Omega \times \tilde{\Omega} \to \mathbb{R}_+^N \times \tilde{\Omega}$ by $\tilde{\Psi}_{\tilde{u}(k)}(\omega, \tilde{\omega}) = (\tilde{u}(k), \omega, \tilde{\omega})$, which is Borel-measurable. Then we have

$$\tilde{\varphi}(\tilde{u}(k), \tilde{T}_{(k+1, N)}(\omega, \tilde{\omega}), \omega) = h \circ \tilde{\Psi}_{\tilde{u}(k)}(\omega, \tilde{\omega}) = h(\tilde{u}(k), \omega, \tilde{\omega}),$$

which is upper semianalytic on $\Omega \times \tilde{\Omega}$ by the first part of point 3 of Lemma 4.6. By using similar arguments and the fact that $g$ is upper semianalytic, we can also show that $\tilde{\varphi}(\tilde{u}(k), \omega)$ is upper semianalytic on $\Omega$.

The consistency condition in (4.12) follows by the same arguments as Theorem 2.18 in [5]. This is possible as $\{\tau_i > t\}, \{\tau_i = t\}, \{\tau_i \leq t\}$ are disjoint events and

$$\tilde{P}(t; \tilde{P}) = \{\tilde{P}' \circ \tilde{P} = P \circ \tilde{P} \text{ on } G_{1}^{(N)}\} = \{\tilde{P}' \in \tilde{P} : P' = P \text{ on } F_t\}.$$

\hfill \Box

**Proposition 4.8.** Let $t \geq 0$ and $Y$ satisfy the assumptions in Proposition 4.7. The function $\tilde{E}_1^{(N)}(Y)$ defined in (4.11) is upper semianalytic and measurable with respect to $G_{1}^{(N),*}$ and $\mathcal{G}^P$.

**Proof.** This follows by the same arguments as Proposition 2.21 in [5].

For $m = 1, ..., M$ and $Y$ satisfying the assumptions of Proposition 4.7 we denote by $\tilde{E}_m$ the following operator

$$\tilde{E}_m(Y) := 1_{\{t < \tau_1\}} \mathcal{E}_t \left( \int_0^t \tilde{\lambda}_s ds \mathbb{E}^P \left[ 1_{\{t < \tau_1\}} Y \right] \right)$$

$$+ \sum_{k=1}^{m-1} 1_{\{\tau_k \leq t < \tau_{k+1}\}} \mathcal{E}_t \left( \int_0^{t-\tau_k} \tilde{\lambda}_{s+} ds \mathbb{E}^P \left[ 1_{\{t-\tau_k > t-\tau_k\}} \tilde{\varphi}(u(k), \tilde{u}(k+1), ..., \tilde{u}(k+m), \cdot) \right] \right) \bigg|_{u(k) = \tau(k)}$$

$$+ 1_{\{\tau_m \leq t\}} \mathcal{E}_t(\tilde{\varphi}(u(m), \cdot)) \bigg|_{u(m) = \tau(m)}.$$  \hfill (4.15)

**Proposition 4.9.** Let $Y$ satisfy the assumptions in Proposition 4.7. Then:

1. If $Y$ is $\mathcal{F}_{\infty}^P$-measurable, then $\tilde{E}_1^{(N)}(Y)$ coincides with $\mathcal{E}_t(Y)$ for $t \geq 0$.

2. If $Y$ is $G_{\infty}^{(m),P}$-measurable, then $\tilde{E}_1^{(N)}(Y)$ coincides with $\tilde{E}_m(Y)$ for $t \geq 0$ and $m = 1, ..., N$.

For $m = 1$, the operator $\tilde{E}_1^1$ is the one defined in Theorem 2.18 in [5].

**Proof.** 1. If $Y$ is $\mathcal{F}_{\infty}^P$-measurable, then $Y(\tilde{\omega}) = Y(\omega, \tilde{\omega}) = Y(\omega)$. Therefore, by Definition 4.3 we get

$$\tilde{E}_1^{(N)}(Y) = 1_{\{t < \tau_1\}} \mathcal{E}_t \left( \int_0^t \tilde{\lambda}_s ds \mathbb{E}^P \left[ 1_{\{t < \tau_1\}} Y \right] \right)$$

$$+ \sum_{k=1}^{N-1} 1_{\{\tau_k \leq t < \tau_{k+1}\}} \mathcal{E}_t \left( \int_0^{t-\tau_k} \tilde{\lambda}_{s+} ds \mathbb{E}^P \left[ 1_{\{t-\tau_k > t-\tau_k\}} Y \right] \right) \bigg|_{u(k) = \tau(k)}$$

$$+ 1_{\{\tau_N \leq t\}} \mathcal{E}_t(Y)$$

$$= 1_{\{t < \tau_1\}} \mathcal{E}_t \left( \int_0^t \tilde{\lambda}_s ds \mathbb{E}^P \left[ 1_{\{t < \tau_1\}} Y \right] \right).$$
2. Let \( m = 1, \ldots, N \). If \( Y \) is \( \mathcal{G}_{\infty}^{(m)} \)-measurable, we can write

\[
Y(\omega, \hat{\omega}) = \varphi(\tau_1(\omega, \hat{\omega}), \ldots, \tau_m(\omega, \hat{\omega}), \omega)
\]

with \( \varphi : (\mathbb{R}^m_+ \times \Omega, \mathcal{B}(\mathbb{R}^m_+) \otimes \mathcal{F}_\mathbb{R}) \rightarrow (\mathbb{R}, \mathcal{B}(\mathbb{R})) \). Then for any \( t \geq 0 \) it follows

\[
\tilde{E}_t^N(Y) = 1_{[t < \tau_1]} \tilde{E}_t \left( e^{\int_0^{\tau_1} \tilde{X}_s \, ds} E^{P} \left[ 1_{[t < \tau_1]} Y \right] \right)
\]

\[
+ \sum_{k=1}^{m-1} 1_{[\tau_k < t < \tau_{k+1}]} \tilde{E}_t \left( e^{\int_0^{\tau_{k+1}} \tilde{X}_s \, ds} E^{P} \left[ 1_{[\tau_{k+1} > t - u_k]} \varphi(u_k, u_{k+1}^\tau, \ldots, u_{m,m}^\tau) \right] \right) \bigg|_{u_k = \tau_k}
\]

\[
+ 1_{[\tau_N \leq t]} \tilde{E}_t(Y)
\]

\[
= 1_{[t < \tau_1]} \tilde{E}_t \left( e^{\int_0^{\tau_1} \tilde{X}_s \, ds} E^{P} \left[ 1_{[t < \tau_1]} Y \right] \right)
\]

\[
+ \sum_{k=1}^{m-1} 1_{[\tau_k < t < \tau_{k+1}]} \tilde{E}_t \left( e^{\int_0^{\tau_{k+1}} \tilde{X}_s \, ds} E^{P} \left[ 1_{[\tau_{k+1} > t - u_k]} \varphi(u_k, u_{k+1}^\tau, \ldots, u_{m,m}^\tau) \right] \right) \bigg|_{u_k = \tau_k}
\]

\[
+ 1_{[\tau_N \leq t]} \tilde{E}_t(Y)
\]

\[
= 1_{[t < \tau_1]} \tilde{E}_t(Y) + \sum_{k=1}^{N-1} 1_{[\tau_k < t < \tau_{k+1}]} \tilde{E}_t(Y) + 1_{[\tau_N \leq t]} \tilde{E}_t(Y)
\]

\[
= \tilde{E}_t(Y).
\]
\[ + 1_{\{r_m \leq t\}} \hat{E}_t(\varphi(u_{(m)}, \cdot)) \big|_{u_{(m)} = \tau_{(m)}} = \hat{E}_t^m(Y). \]

We now prove some consistency properties.

**Proposition 4.10.** Let \( t \geq 0 \) and \( Y \) satisfy the assumptions in Proposition 4.7. Then the following holds:

1. If \( X \) is an upper semianalytic function on \( \tilde{\Omega} \) such that \( X \in L^1(\tilde{\Omega}) \) and
\[
\text{ess sup}_{P \in \tilde{P}(t, \tilde{P})} \mathbb{E}^P \left[ Y \mathbb{G}_t^{(N)} \right] = \text{ess sup}_{P \in \tilde{P}(t, \tilde{P})} \mathbb{E}^P \left[ X \mathbb{G}_t^{(N)} \right] \quad \tilde{P}\text{-a.s. for all } \tilde{P} \in \tilde{P},
\]
then \( \hat{E}_t^N(X) = \hat{E}_t^N(Y) \) \( \tilde{P}\text{-a.s. for all } \tilde{P} \in \tilde{P} \).

2. If \( A \in \mathcal{G}_t^{(N)} \), then \( \hat{E}_t^N(1_A Y) = 1_A \hat{E}_t^N(Y) \).

3. The following pathwise equalities hold:
\[ \hat{E}_t^N(1_{\tau_1 > t}) X = 1_{\{\tau_1 > t\}} \hat{E}_t^N(X), \]
\[ \hat{E}_t^N(1_{\tau_k \leq \tau_{k+1} < t}) X = 1_{\{\tau_k \leq \tau_{k+1} < t\}} \hat{E}_t^N(X), \quad k = 1, \ldots, N-1, \quad (4.16) \]
\[ \hat{E}_t^N(1_{\tau_N \leq t}) X = 1_{\{\tau_N \leq t\}} \hat{E}_t^N(X). \]

**Proof.** 1. The first property follows directly by the representation in (4.12).

2. From now on, we fix a given time \( t \geq 0 \) and an event \( A \in \mathcal{G}_t^{(N)} \). By (4.11) we have
\[ \hat{E}_t^N(1_A Y) = 1_{\{\tau_1 > t\}} \hat{E}_t \left( e^{\int_0^t \tilde{\lambda}_k d\mathbb{E}^P[1_{\{t < \tau_1\}} 1_A Y]} \right) \]
\[ + \sum_{k=1}^{N-1} 1_{\{\tau_k \leq t < \tau_{k+1}\}} \hat{E}_t \left( e^{\int_0^t \tilde{\lambda}_k d\mathbb{E}^P[1_{\{t < \tau_k\}} \varphi(u_{(k)}, u_{(k)}, \cdot) \varphi(u_{(k)}, u_{(k)}, \cdot)]} \right) \bigg|_{u_{(k)} = \tau_{(k)}} \]
\[ + 1_{\{\tau_N \leq t\}} \hat{E}_t \left( \varphi(u_{(N)}, \cdot) \varphi(u_{(N)}, \cdot) \right) \big|_{u_{(N)} = \tau_{(N)}}, \]
where
\[ \varphi : (\mathbb{R}^N_+ \times \Omega, \mathcal{B}^{(N)}_+ \otimes \mathcal{F}_t) \to (\mathbb{R}, \mathcal{B}(\mathbb{R})) \]
and
\[ \overline{\varphi} : (\mathbb{R}^N_+ \times \Omega, \mathcal{B}^{(N)}_+ \otimes \mathcal{F}_t) \to (\mathbb{R}, \mathcal{B}(\mathbb{R})) \]
such that
\[ Y(\omega, \tilde{\omega}) = \varphi(\tau_{(N)}(\omega, \tilde{\omega}), \omega) \]
and
\[ 1_A(\omega, \tilde{\omega}) = \overline{\varphi}(\tau_{(N)}(\omega, \tilde{\omega}), \omega). \]

Fix now \( u_{(k)} \in \mathbb{R}^k_+ \) and \( u^k_{(k)} := u_k + \sum_{m=k+1}^l \tilde{\tau}_m \) for \( l = k, \ldots, N \) with \( u^k_{(k)} := u_k \). For every \( l = k, \ldots, N \), we let \( \mathbb{H}^{k,l} = (H_t^{k,l})_{t \geq 0} \) be the filtration generated by the random variable \( u^k_{(k)} \). Note here that \( \mathbb{H}^{k,k} \) is the trivial filtration. Moreover, we introduce the filtration \( \mathbb{H}^{k,l} = (H_t^{k,l})_{t \geq 0} \) as given by \( H_t^{k,l} := \bigvee_{j=k+1}^l H_t^{k,j} \) for \( t \geq 0 \) and \( l = k+1, \ldots, N \). We now show that there exists \( \hat{A}^{k,N} \in \mathcal{F}_t \vee H_t^{k,N} \) such that
\[ \overline{\varphi}(u_{(k)}, u^k_{(k)}, \cdot) = 1_{\hat{A}^{k,N}}. \]

Since \( A \in \mathcal{G}_t^{(N)} \), there exists a measurable function \( f \), constants \( (s_n)_{n=1,\ldots,N} \) such that \( s_n \leq t \) and an \( \mathcal{F}_t \)-measurable random variable \( \mu_t \) such that
\[ 1_A = f(\mu_t, 1_{\{\tau_1 \leq s_1\}}, \ldots, 1_{\{\tau_N \leq s_N\}}). \]
Thus, as \(1_A(\omega, \dot{\omega}) = \varphi(\tau(\omega, \dot{\omega}), \omega)\) for any \((\omega, \dot{\omega}) \in \Omega \times \dot{\Omega}\), we have

\[
\varphi(\tau(\omega, \dot{\omega}), \omega) = f(\mu(\omega), 1_{\{\tau(\omega, \dot{\omega}) \leq s_1\}}, \ldots, 1_{\{\tau(\omega, \dot{\omega}) \leq s_N\}}) = f(\mu(\omega), 1_{\{\tau_1(\omega, \dot{\omega}) \leq s_1\}}, \ldots, 1_{\{\tau_k(\omega, \dot{\omega}) \leq s_k\}}, 1_{\{\tau_k(\omega, \dot{\omega}) + \tau_{k+1}(\omega, \dot{\omega}) \leq s_k+1\}}, \ldots, 1_{\{\tau_k(\omega, \dot{\omega}) + \sum_{i=k+1}^N \tau_i(\omega, \dot{\omega}) \leq s_N\}})
\]

for any \((\omega, \dot{\omega}) \in \Omega \times \dot{\Omega}\).

Then it holds

\[
\varphi(u(k), u^\tau_k(\omega, \dot{\omega}), \omega) = f(\mu(\omega), 1_{\{u_1 \leq s_1\}}, \ldots, 1_{\{u_k(\omega, \dot{\omega}) \leq s_k\}}, 1_{\{u^\tau_{k+1}(\omega, \dot{\omega}) \leq s_{k+1}\}}, \ldots, 1_{\{u^\tau_{N}(\omega, \dot{\omega}) \leq s_N\}})
\]

\[
= 1_{\hat{A}^{k,N}}
\]

where the right-hand side of the first equality is measurable with respect to \(\mathcal{F}_t \vee \mathcal{H}^{k,N}_t\), so that \(\hat{A}^{k,N} \in \mathcal{F}_t \vee \mathcal{H}^{k,N}_t\).

By Lemma 5.1.1 in [7], for any \(\tilde{A}^{k,l} \subset \mathcal{F}_t \vee \mathcal{H}^{l(N)}_t\) there exists \(\tilde{A}^{k,l-1} \subset \mathcal{F}_t \vee \mathcal{H}^{l-1(N)}_t\) such that

\[
\tilde{A}^{k,l} \cap \{u^\tau_k > t\} = \tilde{A}^{k,l-1} \cap \{u^\tau_{k,l} > t\},
\]

where \(l = k+1, \ldots, N\). With the notation introduced above we have that \(\hat{A}^{k,N} \subset \mathcal{F}_t\). Then we get

\[
1_{\{\tau_k \leq \tau_{k+1}\}} \mathcal{E}_t \left(e^{\int_{\tau_k}^{\tau_{k+1}} \hat{\lambda}_{k+1}(\omega, u^\tau_k) dt} \left[1_{\{\tau_{k+1} > t - u_k\}} \varphi(u(k), u^\tau_k, \cdot) \varphi(u(k), u^\tau_k, \cdot) \right] \right)|_{u(k) = \tau(k)}
\]

\[
= 1_{\{\tau_k \leq \tau_{k+1}\}} \mathcal{E}_t \left(e^{\int_{\tau_k}^{\tau_{k+1}} \hat{\lambda}_{k+1}(\omega, u^\tau_k) dt} \left[1_{\{\tau_{k+1} > t - u_k\}} \varphi(u(k), u^\tau_k, \cdot) \right] \right)|_{u(k) = \tau(k)}
\]

\[
= 1_{\{\tau_k \leq \tau_{k+1}\}} \mathcal{E}_t \left(e^{\int_{\tau_k}^{\tau_{k+1}} \hat{\lambda}_{k+1}(\omega, u^\tau_k) dt} \left[1_{\{\tau_{k+1} > t - u_k\}} \varphi(u(k), u^\tau_k, \cdot) \right] \right)|_{u(k) = \tau(k)}
\]

\[
= 1_{\{\tau_k \leq \tau_{k+1}\}} \mathcal{E}_t \left(e^{\int_{\tau_k}^{\tau_{k+1}} \hat{\lambda}_{k+1}(\omega, u^\tau_k) dt} \left[1_{\{\tau_{k+1} > t - u_k\}} \varphi(u(k), u^\tau_k, \cdot) \right] \right)|_{u(k) = \tau(k)}
\]

\[
= 1_{\{\tau_k \leq \tau_{k+1}\}} \mathcal{E}_t \left(e^{\int_{\tau_k}^{\tau_{k+1}} \hat{\lambda}(\omega, u^\tau_k) dt} \left[1_{\{\tau_{k+1} > t - u_k\}} \varphi(u(k), u^\tau_k, \cdot) \right] \right)|_{u(k) = \tau(k)}
\]

\[
= 1_{\{\tau_k \leq \tau_{k+1}\}} \mathcal{E}_t \left(e^{\int_{\tau_k}^{\tau_{k+1}} \hat{\lambda}(\omega, u^\tau_k) dt} \left[1_{\{\tau_{k+1} > t - u_k\}} \varphi(u(k), u^\tau_k, \cdot) \right] \right)|_{u(k) = \tau(k)}
\]

\[
= 1_{\{\tau_k \leq \tau_{k+1}\}} \mathcal{E}_t \left(e^{\int_{\tau_k}^{\tau_{k+1}} \hat{\lambda}(\omega, u^\tau_k) dt} \left[1_{\{\tau_{k+1} > t - u_k\}} \varphi(u(k), u^\tau_k, \cdot) \right] \right)|_{u(k) = \tau(k)}
\]

\[
= 1_{\{\tau_k \leq \tau_{k+1}\}} \mathcal{E}_t \left(e^{\int_{\tau_k}^{\tau_{k+1}} \hat{\lambda}(\omega, u^\tau_k) dt} \left[1_{\{\tau_{k+1} > t - u_k\}} \varphi(u(k), u^\tau_k, \cdot) \right] \right)|_{u(k) = \tau(k)}
\]

\[
= 1_{\{\tau_k \leq \tau_{k+1}\}} \mathcal{E}_t \left(e^{\int_{\tau_k}^{\tau_{k+1}} \hat{\lambda}(\omega, u^\tau_k) dt} \left[1_{\{\tau_{k+1} > t - u_k\}} \varphi(u(k), u^\tau_k, \cdot) \right] \right)|_{u(k) = \tau(k)}
\]

\[
= 1_{\{\tau_k \leq \tau_{k+1}\}} \mathcal{E}_t \left(e^{\int_{\tau_k}^{\tau_{k+1}} \hat{\lambda}(\omega, u^\tau_k) dt} \left[1_{\{\tau_{k+1} > t - u_k\}} \varphi(u(k), u^\tau_k, \cdot) \right] \right)|_{u(k) = \tau(k)}
\]
Note now that all the arguments used in the derivation of (4.28) also work for variable $Z$ of notation $\hat{\tau}$ to denote that we fix with a lemma that is extensively used in the following analysis. The proof follows by (4.9) and the conditional Fubini-Tonelli Theorem.

Proof. We recall that by (3.20) and (5.2) we have that $\mathbb{E}^{\hat{P}}[L^1(\hat{\Omega})]$ is measurable as well as non-negative or $L^1(\hat{\Omega})$, which is well-defined by Proposition 4.8, can be rewritten as

$$\mathbb{E}^{\hat{P}}[L^1(\hat{\Omega})] = \mathbb{E}^{\hat{P}}[\mathcal{F}_t]$$

for $0 \leq s \leq t, k = 1, ..., N$. Note that this is a generalization of Theorem 2.22 in [5], where (5.1) is shown for $k = 1$.

Fix $t \geq 0$ and consider an upper semianalytic function $\tilde{X}$ on $\hat{\Omega}$ such that $\tilde{X} \in L^1(\hat{\Omega})$ or $\tilde{X}$ is $\mathcal{G}^P$-measurable and non-negative. As in (5.2), with a slight notational abuse we introduce the notation

$$E_t(\tilde{X}) := E_t(\tilde{X}(\cdot, \hat{\omega}))(\omega), \quad (\omega, \hat{\omega}) \in \hat{\Omega},$$

(5.2)
to denote that we fix $\hat{\omega}$ and compute the operator $E_t$ on the function $\tilde{X}(\omega, \hat{\omega}), \omega \in \Omega$. We start with a lemma that is extensively used in the following analysis.

Lemma 5.1. For any $t \geq 0$ and any $\mathcal{G}^P$-measurable, upper semianalytic and non-negative random variable $Z$ on $\hat{\Omega}$, it holds

$$\mathbb{E}^{\hat{P}}[E_t(Z)] \geq E_t(\mathbb{E}^{\hat{P}}[Z]).$$

Proof. We recall that by (3.20) and (5.2) we have that

$$\mathbb{E}^{\hat{P}}[E_t(Z)] = \int_{\hat{\Omega}} E_t(Z(\cdot, \hat{\omega}))(\omega)d\hat{P}(\hat{\omega}), \quad \omega \in \Omega.$$ 

(5.3)
The proof follows by (4.9) and the conditional Fubini-Tonelli Theorem.

For brevity reasons, we prove the result for the special case $k = 2$. In this case, the left-hand side in (5.1), which is well-defined by Proposition 4.8, can be rewritten as

$$\mathbb{E}^{\hat{P}}[E_t(Y)] = 1_{\{s < \tau_t\}} E_s \left( e^{\int_s^t \lambda_x d\hat{F}^{\hat{P}}} \left[ 1_{\{s < \tau_t\}} E_t^2(Y) \right] \right)$$

(5.4)

5 Weak dynamic programming principle

In this section we investigate dynamic programming for the operator $\hat{\mathcal{E}}_t^{k}$ for $k = 1, ..., N$. More precisely, consider a $\mathcal{G}^P$-measurable, upper semianalytic and non-negative random variable $Y$ on $\hat{\Omega}$. Under Assumption 4.1 we prove the dynamic programming principle

$$\hat{\mathcal{E}}_s^{k}(\hat{\mathcal{E}}_t^{k}(Y)) \geq \hat{\mathcal{E}}_s^{k}(Y) \quad \hat{P}\text{-a.s. for all } \hat{P} \in \hat{P},$$

(5.1)

for $0 \leq s \leq t, k = 1, ..., N$. Note that this is a generalization of Theorem 2.22 in [5], where (5.1) is shown for $k = 1$.
for \(0 \leq s < t\) follows from the tower property of \(\phi\).

With this expression in mind, we now proceed to analyze the three terms on the right-hand side of equation (5.4). We start from the third one.

**Proposition 5.2.** For any \(t \geq s \geq 0\), it holds

\[
1_{\{t_s \leq s \leq t\}} \mathcal{E}_s \left( e^{\int_0^{t_s} \lambda^t_{\bar{\tau}} d\bar{\tau} \mathbb{P}} \left[ 1_{\{t \leq \bar{\tau} \leq u_1\}} \varphi_t(u_1, u_1 + \bar{\tau}, \cdot) \right] \right)_{|u_2 = (t_s, t)|} = 1_{\{t_s \leq s \leq t\}} \mathcal{E}_s \left( \varphi(u_1, u_1 + \bar{\tau}, \cdot) \right)_{|u_2 = (t_s, t)|},
\]

where \(\varphi\) is defined in (3.22) and (3.23).

By the definition of \(\mathcal{E}_t\) in (3.11) it follows that for any \((u_1, u_2, \omega) \in \mathbb{R}^2_+ \times \Omega\) it holds

\[
\mathcal{E}_t \left( \varphi_t(u_1, u_2, \cdot) \right)_{|u_2 = (t_s, t)|} = 1_{\{t_s \leq s \leq t\}} \mathcal{E}_s \left( \varphi(u_1, u_1 + \bar{\tau}, \cdot) \right)_{|u_2 = (t_s, t)|}.
\]

With this expression in mind, we now proceed to analyze the three terms on the right-hand side of equation (5.4). We start from the third one.

**Proposition 5.2.** For any \(t \geq s \geq 0\), it holds

\[
1_{\{t_s \leq s \leq t\}} \mathcal{E}_s \left( \varphi_t(u_1, u_2, \cdot) \right)_{|u_1, u_2 = (t_s, t)|} = 1_{\{t_s \leq s \leq t\}} \mathcal{E}_s \left( \varphi(u_1, u_1 + \bar{\tau}, \cdot) \right)_{|u_1, u_2 = (t_s, t)|},
\]

where \(\varphi\) is defined in (3.22) and (3.23) and \(\varphi_t\) given in (5.5).

**Proof.** The proof uses similar arguments as in Theorem 2.22 in [5]. In particular, we have

\[
1_{\{t_s \leq s \leq t\}} \mathcal{E}_s \left( \varphi_t(u_1, u_2, \cdot) \right)_{|u_1, u_2 = (t_s, t)|} = 1_{\{t_s \leq s \leq t\}} \mathcal{E}_s \left( \varphi(u_1, u_1 + \bar{\tau}, \cdot) \right)_{|u_1, u_2 = (t_s, t)|}.
\]

Note that the second equality holds since we deal with disjoint sets, whereas the third equality follows from the tower property of \(\mathcal{E}_t\) stated in (3.8) and since

\[
1_{\{t_s \leq s \leq t\}} 1_{\{t < t_s\}} = 0, \quad 1_{\{t_s \leq s \leq t\}} 1_{\{t_s < t \}} = 0
\]

for \(0 \leq s \leq t\).

We now consider the first term of the right-hand side of (5.4). We start with three lemmas.

**Lemma 5.3.** Let \(Y\) be a \(\mathcal{G}_t\)-measurable, upper semianalytic and non-negative random variable on \(\Omega\). For any \(t \geq 0\), it holds

\[
1_{\{t_2 \leq t\}} \mathcal{E}_t \left( \varphi(u_1, u_2, \cdot) \right)_{|u_1, u_2 = (t_2, t)} = 1_{\{t_2 \leq t\}} \mathcal{E}_t(Y)
\]

where \(\varphi\) is given in (3.22) and (3.23).
Proof. On the event \( \{ \tau_2 \leq t \} \) we have
\[
\tau_1(\omega \otimes_1 \omega', \hat{\omega}) = \tau_1(\omega, \hat{\omega}) \quad \text{for all } \omega' \in \Omega
\]
\[
\tau_2(\omega \otimes_1 \omega', \hat{\omega}) = \tau_2(\omega, \hat{\omega}) \quad \text{for all } \omega' \in \Omega,
\]
as \( \{ \tau_2 \leq t \} \subseteq \{ \tau_1 \leq t \} \). Therefore, on the event \( \{ \tau_2 \leq t \} \) we get by (4.7) and (4.11) that
\[
E_t(Y) = E_t(Y(\cdot, \hat{\omega}))(\omega) = \sup_{P \in \mathcal{P}} \int_{\Omega} Y(\omega \otimes_1 \omega', \hat{\omega})P(\omega')
\]
\[
= \sup_{P \in \mathcal{P}} \int_{\Omega} \varphi(\tau_1(\omega \otimes_1 \omega', \hat{\omega}), \tau_2(\omega \otimes_1 \omega', \hat{\omega}), \omega \otimes_1 \omega')P(\omega')
\]
\[
= \sup_{P \in \mathcal{P}} \int_{\Omega} \varphi(\tau_1(\omega, \hat{\omega}), \tau_2(\omega, \hat{\omega}), \omega \otimes_1 \omega')P(\omega')
\]
\[
= \sup_{P \in \mathcal{P}} \int_{\Omega} \varphi(u_1, u_2, \omega \otimes_1 \omega')P(\omega')|_{(u_1, u_2) = (\tau_1, \tau_2)}
\]
\[
= E_t(\varphi(u_1, u_2, \cdot))(\omega)|_{(u_1, u_2) = (\tau_1(\omega, \hat{\omega}), \tau_2(\omega, \hat{\omega}))}.
\]
for all \( \omega \in \Omega \).

\[
\square
\]

Lemma 5.4. For every non-negative measurable function
\[
\hat{\Psi} : (\mathbb{R}_+^2 \times \Omega, \mathcal{B}(\mathbb{R}) \otimes \mathcal{F}_x^\infty) \to (\mathbb{R}, \mathcal{B}(\mathbb{R}))
\]
we have that
\[
E^\hat{P}[\hat{\Psi}(\tau_1, \widehat{\tau}_2, \cdot)] = E^{\hat{P}}\left[\left(E^\hat{P}[\hat{\Psi}(u_1, \widehat{\tau}_2, \cdot)]\right)|_{u_1 = \tau_1}\right]
\]
and
\[
E^\hat{P}[\hat{\Psi}(\tau_1, \widehat{\tau}_2, \cdot)] = E^{\hat{P}}\left[\left(E^\hat{P}[\hat{\Psi}(\tau_1, u_2, \cdot)]\right)|_{u_2 = \tau_2}\right]. \tag{5.6}
\]
Proof. Fix first \( s_1, s_2 \geq 0 \) and \( A^* \in \mathcal{F}_x^\infty \). Then since \( E_1 \) and \( E_2 \) are independent under \( \hat{P} \), it holds
\[
E^\hat{P}[1_{\{\tau_1 \leq s_1\}}1_{\{\tau_2 \leq s_2\}}1_{\cdot^*}] = 1_{A^*}E^\hat{P}[1_{\{\tau_1 \leq s_1\}}1_{\{\tau_2 \leq s_2\}}] = 1_{A^*}E^\hat{P}[1_{\{\tau_1 \leq s_1\}}|E^\hat{P}[1_{\{\tau_2 \leq s_2\}}]].
\]
On the other hand, we have
\[
E^\hat{P}\left[\left(E^\hat{P}[1_{\{u_1 \leq s_1\}}1_{\{\tau_2 \leq s_2\}}1_{\cdot^*}]\right)|_{u_1 = \tau_1}\right] = 1_{A^*}E^\hat{P}\left[1_{\{u_1 \leq s_1\}}E^\hat{P}[1_{\{\tau_2 \leq s_2\}}]\right]
\]
\[
= 1_{A^*}E^\hat{P}\left[1_{\{\tau_1 \leq s_1\}}E^\hat{P}[1_{\{\tau_2 \leq s_2\}}]\right]
\]
and by the same arguments it follows
\[
E^\hat{P}\left[\left(E^\hat{P}[1_{\{\tau_1 \leq s_1\}}1_{\{\tau_2 \leq s_2\}}1_{\cdot^*}]\right)|_{\tilde{u}_2 = \tau_2}\right] = 1_{A^*}E^\hat{P}\left[1_{\{\tau_1 \leq s_1\}}E^\hat{P}[1_{\{\tau_2 \leq s_2\}}]\right].
\]
Then the result follows by a monotone class argument.

\[
\square
\]

Lemma 5.5. Let \( Y \) be a \( \mathcal{G}^\hat{P} \)-measurable, upper semianalytic and non-negative random variable on \( \Omega \) and \( \hat{\varphi} \) be the unique non-negative, measurable function \( \hat{\varphi} : (\mathbb{R}_+^2 \times \Omega, \mathcal{B}(\mathbb{R}) \otimes \mathcal{F}_x^\infty) \to (\mathbb{R}, \mathcal{B}(\mathbb{R})) \) such that
\[
Y(\omega, \hat{\omega}) = \hat{\varphi}(\tau_1(\omega, \hat{\omega}), \tau_2(\omega, \hat{\omega}), \omega), \quad (\omega, \hat{\omega}) \in \Omega \times \hat{\Omega}. \tag{5.7}
\]
Then for each \( 0 \leq s \leq t \) it holds
\[
E^\hat{P}\left[E_t(\hat{\varphi}(u_1, \tau_2, \cdot)) \right]|_{u_1 = \tau_1} \geq E_t\left(E^\hat{P}[1_{\{s \leq u_1 \leq t\}}\hat{\varphi}(u_1, \tau_2, \cdot)]|_{u_1 = \tau_1}\right). \tag{5.8}
\]
Proof. First note that the existence of such a function $\tilde{\varphi}$ follows by Lemma 3.1. Let $0 \leq s \leq t$. Then for each $P \in \mathcal{P}$ we have

$$\mathbb{E}^P \left[ \mathbb{E}^P \left[ \mathbb{E}^P \left[ 1_{\{s < u_1 \leq t\}} \tilde{\varphi}(u_1, \tilde{r}_2, \cdot) \right] \bigg| u_1 = r_1 \right] \right]$$

$$= \mathbb{E}^P \left[ \mathbb{E}^P \left[ \mathbb{E}^P \left[ 1_{\{s < u_1 \leq t\}} \tilde{\varphi}(u_1, \tilde{r}_2, \cdot) \right] \bigg| u_1 = r_1 \right] \right]$$

$$\geq \mathbb{E}^P \left[ \mathbb{E}^P \left[ \mathbb{E}^P \left[ 1_{\{s < u_1 \leq t\}} \tilde{\varphi}(u_1, \tilde{r}_2, \cdot) \right] \bigg| u_1 = r_1 \right] \right].$$

(5.9)

Here, we apply representation (4.9) in (5.9). We now prove that for each non-negative and measurable function $\tilde{\varphi} : (\mathbb{R}_+^2 \times \Omega, \mathcal{B}(\mathbb{R}_+^2) \otimes \mathcal{F}_t^P) \to (\mathbb{R}, \mathcal{B}(\mathbb{R}))$ it holds

$$\mathbb{E}^P \left[ \mathbb{E}^P \left[ 1_{\{s < u_1 \leq t\}} \tilde{\varphi}(u_1, \tilde{r}_2, \cdot) \bigg| u_1 = r_1 \right] \right] = \mathbb{E}^P \left[ \mathbb{E}^P \left[ 1_{\{s < u_1 \leq t\}} \tilde{\varphi}(u_1, \tilde{r}_2, \cdot) \bigg| u_1 = r_1 \right] \right] P\text{-a.s. for all } P \in \mathcal{P}.$$ 

(5.11)

Fix first $s_1, s_2 \geq 0$ and $A \in \mathcal{F}_t^P$. For every $P \in \mathcal{P}$ we have that

$$\mathbb{E}^P \left[ \mathbb{E}^P \left[ 1_{\{s < u_1 \leq t\}} 1_{\{u_1 \leq s_1\}} 1_{\{\tilde{r}_2 \leq s_2\}} 1_A \bigg| u_1 = r_1 \right] \right]$$

$$= \mathbb{E}^P \left[ \mathbb{E}^P \left[ 1_{\{\tilde{r}_2 \leq s_2\}} 1_A \bigg| \mathbb{E}^P \left[ 1_{\{s < u_1 \leq t\}} 1_{\{u_1 \leq s_1\}} \bigg| u_1 = r_1 \right] \right] \right]$$

$$= \mathbb{E}^P \left[ 1_{\{s < r_1 \leq t \wedge s_1\}} 1_A \bigg| \mathbb{E}^P \left[ 1_{\{\tilde{r}_2 \leq s_2\}} \bigg| u_1 = r_1 \right] \right]$$

$$= \mathbb{E}^P \left[ 1_{\{s < r_1 \leq t \wedge s_1\}} \mathbb{E}^P \left[ 1_{\{\tilde{r}_2 \leq s_2\}} 1_A \bigg| u_1 = r_1 \right] \right]$$

(5.12)

where we use in (5.12) that $\mathbb{E}^P \left[ 1_{\{\tilde{r}_2 \leq s_2\}} 1_A \bigg| u_1 = r_1 \right]$ is independent of $\tilde{\omega}$. Moreover, (5.13) follows as $\mathbb{E}^P \left[ 1_{\{s < r_1 \leq t \wedge s_1\}} \right] = -e^{- \int_0^{\tilde{r}_1} \lambda_s^{d-1} \lambda_t^{d-1} r} e^{- \int_0^{\tilde{r}_1} \lambda_t^{d-1} r}$ is $\mathcal{F}_t$-measurable. Then we get (5.11) by using a monotone class argument. Note now that (5.11) implies

$$\mathbb{E}^P \left[ \mathbb{E}^P \left[ 1_{\{s < u_1 \leq t\}} \tilde{\varphi}(u_1, \tilde{r}_2, \cdot) \bigg| u_1 = r_1 \right] \right]$$

$$\geq \mathbb{E}^P \left[ \mathbb{E}^P \left[ 1_{\{s < u_1 \leq t\}} \tilde{\varphi}(u_1, \tilde{r}_2, \cdot) \bigg| u_1 = r_1 \right] \right]$$

(5.14)

by using (13) in (5.14). Putting together the inequalities (5.10) and (5.14) yields (5.8).

The next lemma provides a fundamental step in the computations on the second term of the right-hand side of (5.4).

Lemma 5.6. Let $Y$ be a $\mathcal{G}_t^P$-measurable, upper semianalytic and non-negative random variable on $\Omega$. For any $0 \leq s \leq t$ it holds

$$\mathbb{E}^P \left[ 1_{\{s < r_1 \leq t < \tilde{r}_2\}} \mathbb{E}^P \left[ 1_{\{\tilde{r}_2 \geq t - u_1\}} \tilde{\varphi}(u_1, u_1 + \tilde{r}_2, \cdot) \right] \bigg| u_1 = r_1 \right] \right] \geq \mathbb{E}^P \left[ 1_{\{s < r_1 \leq t \leq \tilde{r}_2\}} Y \right],$$

(5.15)

where $\varphi$ is given in (3.22) and (3.23).
Proof. Since the operator $E_t$ is $\mathcal{F}_{\infty}^*$-measurable, and considering a generalized version of Lemma \[5.7\] where the reference filtration at final time is now $\mathcal{F}_s^*$, we can apply Lemma \[5.4\] to the function $\Psi : (\mathbb{R}_+^2 \times \Omega, B(\mathbb{R}_+) \otimes \mathcal{F}_{\infty}^*) \to (\mathbb{R}, B(\mathbb{R}))$ given by

$$
\Psi(t_1, \tilde{\tau}, \omega) := 1_{\{s < t \leq 1\}} 1_{\{t_2 > t - \tilde{\tau}_1\}} E_t \left( e^{t_0 - t - \tilde{\tau}_1} \tilde{\lambda}_d^2 dt \tilde{\Omega}_t \left[ 1_{\{t_2 > t - u\}} \varphi(u_1, u_1 + \tilde{\tau}_2, \cdot) \right] \right) \bigg|_{u_1 = \tau_1}.
$$

(5.16)

Then we get

$$
E^P \left[ 1_{\{s < \tau_1 \leq t \}} 1_{\{\tau_1 \leq t \}} E_t \left( e^{t_0 - t - \tilde{\tau}_1} \tilde{\lambda}_d^2 dt \tilde{\Omega}_t \left[ 1_{\{t_2 > t - u\}} \varphi(u_1, u_1 + \tilde{\tau}_2, \cdot) \right] \right) \right] \bigg|_{u_1 = \tau_1}.
$$

(5.17)

$$
E^P \left[ \tilde{\Omega}_t \left[ 1_{\{s < \tau_1 \leq t \}} 1_{\{\tau_1 \leq t \}} E_t \left( e^{t_0 - t - \tilde{\tau}_1} \tilde{\lambda}_d^2 dt \tilde{\Omega}_t \left[ 1_{\{t_2 > t - u\}} \varphi(u_1, u_1 + \tilde{\tau}_2, \cdot) \right] \right) \right] \right] \bigg|_{u_1 = \tau_1}.
$$

(5.18)

$$
E^P \left[ \tilde{\Omega}_t \left[ 1_{\{s < \tau_1 \leq t \}} 1_{\{\tau_1 \leq t \}} E_t \left( e^{t_0 - t - \tilde{\tau}_1} \tilde{\lambda}_d^2 dt \tilde{\Omega}_t \left[ 1_{\{t_2 > t - u\}} \varphi(u_1, u_1 + \tilde{\tau}_2, \cdot) \right] \right) \right] \right] \bigg|_{u_1 = \tau_1}.
$$

(5.19)

$$
E^P \left[ \tilde{\Omega}_t \left[ 1_{\{s < \tau_1 \leq t \}} 1_{\{\tau_1 \leq t \}} E_t \left( e^{t_0 - t - \tilde{\tau}_1} \tilde{\lambda}_d^2 dt \tilde{\Omega}_t \left[ 1_{\{t_2 > t - u\}} \varphi(u_1, u_1 + \tilde{\tau}_2, \cdot) \right] \right) \right] \right] \bigg|_{u_1 = \tau_1}.
$$

(5.20)

Here we obtain \[5.17\] by Lemma \[5.4\] whereas \[5.18\] follows from the fact that for fixed $\omega \in \tilde{\Omega}$ the indicator function $1_{\{t_2 > t - u\}}$ is $\mathcal{F}_s^*$-measurable and from Remark 2.4 (iv) in \[27\]. Inequality \[5.19\] comes directly from Lemma \[5.3\] whereas \[5.20\] follows by applying Lemma \[5.4\] to $Y := 1_{\{t_2 > t - u\}} Y$, which is again a $\mathcal{G}^P$-measurable, upper semianalytic and non-negative random variable on $\tilde{\Omega}$. Finally, \[5.21\] by Lemma \[5.3\] applied to $Y 1_{\{s < \tau_1 \leq t \}}$.

We are now ready to give the next proposition, which takes into account the first term of the right-hand side of \[5.4\].

Proposition 7.7. Let $Y$ be a $\mathcal{G}^P$-measurable, upper semianalytic and non-negative random variable on $\tilde{\Omega}$. For any $0 \leq s \leq t$ it holds

$$
1_{\{s < \tau_1 \}} E_s \left( e^{t_0 - t - \tilde{\tau}_1} \tilde{\lambda}_d^2 dt \tilde{\Omega}_t \left[ 1_{\{s < \tau_1 \}} \tilde{\Omega}^2 (Y) \right] \right) \geq 1_{\{s < \tau_1 \}} E_s \left( e^{t_0 - t - \tilde{\tau}_1} \tilde{\lambda}_d^2 dt \tilde{\Omega}_t \left[ 1_{\{s < \tau_1 \}} Y \right] \right).
$$

(5.22)

Proof. From Definition \[4.12\] we get

$$
1_{\{s < \tau_1 \}} E_s \left( e^{t_0 - t - \tilde{\tau}_1} \tilde{\lambda}_d^2 dt \tilde{\Omega}_t \left[ 1_{\{s < \tau_1 \}} \tilde{\Omega}^2 (Y) \right] \right)
$$

$$
= 1_{\{s < \tau_1 \}} E_s \left( e^{t_0 - t - \tilde{\tau}_1} \tilde{\lambda}_d^2 dt \tilde{\Omega}_t \left[ 1_{\{s < \tau_1 \}} \tilde{\Omega}_t \left( e^{t_0 - t - \tilde{\tau}_1} \tilde{\lambda}_d^2 dt \tilde{\Omega}_t \left[ 1_{\{s < \tau_1 \}} Y \right] \right) \right) \right)
$$

$$
+ 1_{\{\tau_1 \leq \tau \leq \tilde{\tau}_2 \}} E_t \left( e^{t_0 - t - \tilde{\tau}_1} \tilde{\lambda}_d^2 dt \tilde{\Omega}_t \left[ 1_{\{t_2 > t - \tau \}} \varphi(u_1, u_1 + \tilde{\tau}_2, \cdot) \right] \right) \bigg|_{u_1 = \tau_1}.
$$

21
Moreover, following the same arguments as in the proof of Theorem 2.22 of [5] we get
\[
\mathbb{E}\left[1_{\{s<\tau_1\}} 1_{\{t<\tau_1\}} E_t \left(e^{\int_{s}^{\tau_1} \lambda_1^{(s)} dv} \mathbb{E}\left[1_{\{t<\tau_1\}} Y\right]\right)\right] = E_t \left(e^{\int_{s}^{\tau_1} \lambda_1^{(s)} dv} \mathbb{E}\left[1_{\{t<\tau_1\}} Y\right]\right)
\]
\[
\geq E_t \left(\mathbb{E}\left[1_{\{s<\tau_1\}} 1_{\{t<\tau_2\}} Y\right]\right).
\]
By Lemma 5.6 we have
\[
\mathbb{E}\left[1_{\{s<\tau_1\}} 1_{\{t<\tau_2\}} E_t \left(e^{\int_{s}^{\tau_1} \lambda_1^{(s)} dv} \mathbb{E}\left[1_{\{t<\tau_1\}} Y\right]\right)\right] \geq E_t \left(\mathbb{E}\left[1_{\{s<\tau_1\}} 1_{\{t<\tau_2\}} Y\right]\right).
\]
By Lemma 5.3 it follows that
\[
\mathbb{E}\left[1_{\{s<\tau_1\}} 1_{\{t<\tau_2\}} E_t \left(e^{\int_{s}^{\tau_1} \lambda_1^{(s)} dv} \mathbb{E}\left[1_{\{t<\tau_1\}} Y\right]\right)\right] = \mathbb{E}\left[1_{\{s<\tau_1\}} 1_{\{t<\tau_2\}} E_t (Y)\right].
\]
Putting together (5.23), (5.24), (5.25), (5.26) and Remark 2.4 (iii) in [27], with the notation (5.24), we get that
\[
1_{\{s<\tau_1\}} E_t \left(e^{\int_{s}^{\tau_1} \lambda_1^{(s)} dv} \mathbb{E}\left[1_{\{s<\tau_1\}} E_t (Y)\right]\right) \geq 1_{\{s<\tau_1\}} E_t \left(e^{\int_{s}^{\tau_1} \lambda_1^{(s)} dv} \mathbb{E}\left[1_{\{s<\tau_1\}} 1_{\{t<\tau_2\}} Y\right]\right) + \mathbb{E}\left[1_{\{s<\tau_1\}} 1_{\{t<\tau_2\}} E_t (Y)\right]
\]
\[
= 1_{\{s<\tau_1\}} E_t \left(e^{\int_{s}^{\tau_1} \lambda_1^{(s)} dv} \mathbb{E}\left[1_{\{s<\tau_1\}} 1_{\{t<\tau_2\}} Y\right]\right) + \mathbb{E}\left[1_{\{s<\tau_1\}} 1_{\{t<\tau_2\}} E_t (Y)\right]
\]
\[
= 1_{\{s<\tau_1\}} E_t \left(e^{\int_{s}^{\tau_1} \lambda_1^{(s)} dv} \mathbb{E}\left[1_{\{s<\tau_1\}} 1_{\{t<\tau_2\}} Y\right]\right)
\]
where we use Lemma 5.6 in (5.27). Equality (5.28) holds by Remark 2.4 (iv) in [27] together with the fact that
\[
\{s < \tau_1(\cdot, \bar{\omega}), \{\tau_2(\cdot, \bar{\omega}) \leq t\} \in \mathcal{F}_t \}
\]
for fixed \(\bar{\omega} \in \bar{\Omega}\). Inequality (5.29) follows from Lemma 5.1 and (5.30) by the sublinearity of \(E_t\). Finally, the tower property of \(E_t\) implies (5.31).

We finally consider the second term of the right-hand side of (5.31), i.e.
\[
1_{\{\tau_1 \leq s < \tau_2\}} E_s \left(e^{\int_{s}^{\tau_1} \lambda_1^{(s)} dv} \mathbb{E}\left[1_{\{\tau_2 > \tau_1\}} \varphi_t(u_1, u_1 + \tau_2, \cdot)\right]\right) \bigg|_{u_1 = \tau_1}.
\]

**Proposition 5.8.** For any \(0 \leq s \leq t\) it holds
\[
1_{\{\tau_1 \leq s < \tau_2\}} E_s \left(e^{\int_{s}^{\tau_1} \lambda_1^{(s)} dv} \mathbb{E}\left[1_{\{\tau_2 > s - u_1\}} \varphi_t(u_1, u_1 + \tau_2, \cdot)\right]\right) \bigg|_{u_1 = \tau_1}
\]
\[
\geq 1_{\{\tau_1 \leq s < \tau_2\}} E_s \left(e^{\int_{s}^{\tau_1} \lambda_1^{(s)} dv} \mathbb{E}\left[1_{\{\tau_2 > s - u_1\}} \varphi(u_1, u_1 + \tau_2, \cdot)\right]\right) \bigg|_{u_1 = \tau_1},
\]
where \(\varphi_t\) is defined in (5.35) and \(\varphi\) is given in (3.22) and (3.23).
Proof. From (5.3) we get

\[ 1_{\{\tau_i \leq s < \tau_j\}} \mathcal{E}_s \left( e^{\int_{t_{\tau_i}}^{t_s} \lambda_s^2 \text{d}v \mathbb{P}} \left[ 1_{\{\tau_j > s - u_1\}} \varphi_s(u_1, u_1 + \tau_s) \right] \right) \bigg|_{u_1 = \tau_i} \]

\[ = 1_{\{\tau_i \leq s < \tau_j\}} \mathcal{E}_s \left( e^{\int_{t_{\tau_i}}^{t_s} \lambda_s^2 \text{d}v \mathbb{P}} \left[ 1_{\{\tau_j > s - u_1\}} \left\{ 1_{\{u_1 > t\}} \mathcal{E}_t (e^{\int_{t_{\tau_i}}^{t_s} \lambda_s^2 \text{d}v \mathbb{P}} [1_{\{\tau_j > t - u_1\}} \varphi(u_1, u_1 + \tau_s)] + 1_{\{u_1 + \tau_s \leq t\}} \mathcal{E}_t (\varphi(u_1, u_1 + \tau_s + \tau_s)) \right) \right] \right) \bigg|_{u_1 = \tau_i} \]  

(5.34)

Since \( 1_{\{u_1 > t\}} \mathcal{E}_t (e^{\int_{t_{\tau_i}}^{t_s} \lambda_s^2 \text{d}v \mathbb{P}} [1_{\{\tau_j > t - u_1\}} \varphi(u_1, u_1 + \tau_s)] \) is independent of \( \hat{\omega} \), we have

\[ \mathbb{E}^\hat{\omega} \left[ 1_{\{\tau_j > s - u_1\}} \left\{ 1_{\{u_1 > t\}} \mathcal{E}_t (e^{\int_{t_{\tau_i}}^{t_s} \lambda_s^2 \text{d}v \mathbb{P}} [1_{\{\tau_j > t - u_1\}} \varphi(u_1, u_1 + \tau_s)] + 1_{\{u_1 + \tau_s \leq t\}} \mathcal{E}_t (\varphi(u_1, u_1 + \tau_s + \tau_s)) \right) \right] \]

\[ = 1_{\{u_1 \leq t\}} \mathcal{E}_t (e^{\int_{t_{\tau_i}}^{t_s} \lambda_s^2 \text{d}v \mathbb{P}} [1_{\{\tau_j > t - u_1\}} \varphi(u_1, u_1 + \tau_s)]) \]  

(5.35)

Also note that \( 1_{\{u_1 \leq t\}} \mathcal{E}_t (e^{\int_{t_{\tau_i}}^{t_s} \lambda_s^2 \text{d}v \mathbb{P}} [1_{\{\tau_j > t - u_1\}} \varphi(u_1, u_1 + \tau_s)]) \) is independent of \( \hat{\omega} \), so that

\[ \mathbb{E}^\hat{\omega} \left[ 1_{\{\tau_j > s - u_1\}} 1_{\{u_1 \leq t\}} \mathcal{E}_t (e^{\int_{t_{\tau_i}}^{t_s} \lambda_s^2 \text{d}v \mathbb{P}} [1_{\{\tau_j > t - u_1\}} \varphi(u_1, u_1 + \tau_s)]) \right] \]

\[ = 1_{\{u_1 \leq t\}} \mathcal{E}_t (e^{\int_{t_{\tau_i}}^{t_s} \lambda_s^2 \text{d}v \mathbb{P}} [1_{\{\tau_j > t - u_1\}} \varphi(u_1, u_1 + \tau_s)]) \]  

(5.36)

Putting together (5.35), (5.36) and Remark 2.4 (iii) in [27], we have that the right-hand side of (5.34) is equal to

\[ 1_{\{\tau_i \leq s < \tau_j\}} e^{\int_{t_{\tau_i}}^{t_s} \lambda_s^2 \text{d}v \mathbb{E}_s} \left( e^{\int_{t_{\tau_i}}^{t_s} \lambda_s^2 \text{d}v \mathbb{P}} [1_{\{\tau_j > t - u_1\}} \varphi(u_1, u_1 + \tau_s)] + 1_{\{u_1 \leq t\}} \mathcal{E}_t (e^{\int_{t_{\tau_i}}^{t_s} \lambda_s^2 \text{d}v \mathbb{P}} [1_{\{\tau_j > t - u_1\}} \varphi(u_1, u_1 + \tau_s)]) \right) \bigg|_{u_1 = \tau_i} \]

(5.37)

\[ = 1_{\{\tau_i \leq s < \tau_j\}} e^{\int_{t_{\tau_i}}^{t_s} \lambda_s^2 \text{d}v \mathbb{E}_s} \left( \mathcal{E}_t (1_{\{u_1 \leq t\}} \mathbb{E}^\hat{\omega} [1_{\{\tau_j > t - u_1\}} \varphi(u_1, u_1 + \tau_s)]) \right) \bigg|_{u_1 = \tau_i} \]

(5.38)

\[ \geq 1_{\{\tau_i \leq s < \tau_j\}} e^{\int_{t_{\tau_i}}^{t_s} \lambda_s^2 \text{d}v \mathbb{E}_s} \left( \mathcal{E}_t (e^{\int_{t_{\tau_i}}^{t_s} \lambda_s^2 \text{d}v \mathbb{P}} [1_{\{\tau_j > t - u_1\}} \varphi(u_1, u_1 + \tau_s)]) \right) \bigg|_{u_1 = \tau_i} \]

(5.39)

\[ \geq 1_{\{\tau_i \leq s < \tau_j\}} e^{\int_{t_{\tau_i}}^{t_s} \lambda_s^2 \text{d}v \mathbb{E}_s} \left( \mathcal{E}_t (e^{\int_{t_{\tau_i}}^{t_s} \lambda_s^2 \text{d}v \mathbb{P}} [1_{\{\tau_j > t - u_1\}} \varphi(u_1, u_1 + \tau_s)]) \right) \bigg|_{u_1 = \tau_i} \]
5.10. Remark 2.4 (iv) in [27] and (5.32). The inequality in (5.39) follows by Lemma 5.1 and the
is

Putting together Definition 4.4 with Propositions 5.2, 5.7 and 5.8, we then get the following

in [7]. Standard products in this class of derivatives are given by the collection of the so called

to default contingent claim CCT

the payoff of the claim CCT

• If \( \tau \leq T \), then the claim pays the amount \( Z_{\tau} \) at time \( \tau \), where \( Z_t \) is given by a \( \mathcal{G}^{(N)} \)-
predictable process, and a \( \mathcal{G}^{(N)}_T \)-measurable amount \( X_t \) at time \( T \).

• If \( \tau > T \), the holder receives an amount \( X \) at time \( T \), where \( X \) is given by a non-negative
and \( \mathcal{G}^{(N)}_T \)-measurable random variable.

Note that the equality (5.37) holds as \( 1_{\{u_1 \leq s \}}1_{\{u_1 \geq t \}} = 0 \) for \( 0 \leq s \leq t \), whereas in (5.38) we use
again Remark 2.4 (iv) in [27] and (5.32). The inequality in (5.39) follows by Lemma 5.1 and the
one in (5.40) by the sublinearity of \( \mathcal{E} \). As \( 1_{\{\tau_2 > t - u_1 \}}1_{\{\tau_2 > s - u_1 \}} = 1_{\{\tau_2 > t - u_1 \}} \), we have

\[
1_{\{u_1 \leq t \}}1_{\{\tau_2 > t - u_1 \}} + 1_{\{\tau_2 > s - u_1 \}}1_{\{u_1 + \tilde{\tau}_2 \leq t \}} \\
= 1_{\{\tau_2 > s - u_1 \}}1_{\{u_1 \leq t \}}1_{\{\tau_2 > t - u_1 \}} + 1_{\{u_1 + \tilde{\tau}_2 \leq t \}} \\
= 1_{\{\tau_2 > s - u_1 \}}1_{\{u_1 \leq t \}}1_{\{\tau_2 > t - u_1 \}} + 1_{\{u_1 + \tilde{\tau}_2 \leq t \}}1_{\{u_1 + \tilde{\tau}_2 \leq t \}} \\
= 1_{\{\tau_2 > s - u_1 \}}1_{\{u_1 \leq t \}}1_{\{\tau_2 > t - u_1 \}} + 1_{\{u_1 + \tilde{\tau}_2 \leq t \}}1_{\{u_1 + \tilde{\tau}_2 \leq t \}} \\
= 1_{\{\tau_1 \leq s < \tau_2 \}}1_{\{\tau_1 \leq t \}},
\]

where we use in (5.43) that \( 1_{\{u_1 \leq t \}}1_{\{u_1 + \tilde{\tau}_2 \leq t \}} = 0 \), as \( \tilde{\tau}_2 \) is non-negative. Then (5.41) follows by
(5.44). Then (5.42) holds by the tower property of \( \mathcal{E} \) and we use that for \( 0 \leq s \leq t \)

\[
1_{\{\tau_1 \leq s < \tau_2 \}}1_{\{\tau_1 \leq t \}} = 1_{\{\tau_1 \leq s < \tau_2 \}}.
\]

Putting together Definition 4.4 with Propositions 5.2, 5.7 and 5.8 we then get the following
theorem.

**Theorem 5.9.** Let Assumption 4.1 hold and \( Y \) be an upper semianalytic function on \( \tilde{\Omega} \) such that
\( Y \) is \( \mathcal{G}^T \)-measurable and non-negative. Then for any \( 0 \leq s \leq t, k = 1, \ldots, N \) it holds

\[
\mathcal{E}^k_s(\mathcal{E}^k_t(Y)) \geq \mathcal{E}^k_s(Y) \quad \tilde{P}\text{-a.s. for all } \tilde{P} \in \tilde{P}.
\]

**Proof.** For \( k = 3, \ldots, N \) the result follows by similar arguments as in the Propositions 5.2, 5.7 and
5.8.

6 Valuation of credit portfolio products in a multiple default setting under model uncertainty

In this section we study the valuation of basket credit derivatives in a multiple default setting under
model uncertainty. For more details on these insurance products we refer to Section 9.1 in [7]. Standard products in this class of derivatives are given by the collection of the so called \( i \)-th to default contingent claim CCT\((i)\) with maturity \( T > 0 \) for any \( i = 1, \ldots, N \). In the framework
outlined in Section 2 we assume that the multiple defaults are represented by a collection of ordered
stopping times \( \{\tau_i\}_{1 \leq i \leq N} \) constructed as in (23) and (24). In this setting, for any \( i = 1, \ldots, N \), the payoff of the claim CCT\((i)\) is defined as follows:

- If \( \tau_i \leq T \), then the claim pays the amount \( Z_{\tau_i} \) at time \( \tau_i \), where \( Z^i \) is given by a \( \mathcal{G}^{(N)} \)-
predictable process, and a \( \mathcal{G}^{(N)}_T \)-measurable amount \( X^i \) at time \( T \).

- If \( \tau_i > T \), the holder receives an amount \( X \) at time \( T \), where \( X \) is given by a non-negative
and \( \mathcal{G}^{(N)}_T \)-measurable random variable.
We now evaluate a special type of these contracts by using the operator $\tilde{E}^N$ in the following setting. For the financial interpretation of $\tilde{E}^N$ as pricing operator, we refer to Section 7.

Let $T < \infty$ be the maturity time. We define the filtration $\mathbb{F}_t^P := (\mathcal{F}_t^P)_{t \in [0, T]}$ by

$$\mathcal{F}_t^P := \mathcal{F}_t \vee \mathcal{N}_t^P, \quad t \in [0, T],$$

(6.1)

where $\mathcal{N}_t^P$ is the collection of sets which are $(P, \mathcal{F}_T)$-null for all $P \in \mathcal{P}$. For fixed $i = 1, \ldots, N$ we consider a product associated to the $i$-th default event, defined in particular by the following payoff:

1. $1_{(\tau_i > T)} Y_i$, where $Y$ is a $\mathcal{F}_T^P$-measurable, non-negative and upper semianalytic function on $\Omega$, such that $\mathcal{E}(Y) < \infty$;

2. $1_{(0 < \tau_i \leq T)} Z_{\tau_i}$, where $Z = (Z_t)_{t \in [0, T]}$ is an $\mathcal{F}_T^P$-predictable non-negative process on $\Omega$, such that the function $Z(t, \omega) := Z_t(\omega)$, $(t, \omega) \in [0, T] \times \Omega$, is upper semianalytic and $\sup_{t \in [0, T]} \mathcal{E}(Z_t) < \infty$.

The payoff defined above can be seen as a particular case of a CCT$^i$, for any fixed $i = 1, \ldots, N$, and as a generalization for multiple default times of the insurance products studied in Section 2.4 of [5]. Before we evaluate this payoff for $N = 2$, we state an auxiliary lemma which we need in the following.

**Lemma 6.1.** Fix $\omega \in \Omega$ and let $h : (\mathbb{R}^+ \times \Omega, \mathcal{B}(\mathbb{R}^+) \otimes \mathcal{F}_T^P) \rightarrow (\mathbb{R}, \mathcal{B}(\mathbb{R}))$ be a function such that $\mathbb{E}^P [|h(\tilde{\tau}_i(\omega), \omega))|] < \infty,$ $i = 1, 2$. Then we have

$$\mathbb{E}^P \left[ 1_{\{s < \tilde{\tau}_i(\omega) \leq t\}} h(\tilde{\tau}_i(\omega), \omega) \right] = \int_t^s h(x, \omega)e^{-\int_t^x \lambda_i(y)dy}\tilde{\lambda}_i^1(\omega)dx$$

(6.2)

for all $0 \leq s \leq t \leq T$ and $i = 1, 2$.

**Proof.** Let $i = 1, 2$. For fixed $\omega \in \Omega$ and $u \geq 0$ it holds

$$P(\tilde{\tau}_i(\omega, \omega) \leq u) = 1 - P(\tilde{\tau}_i(\omega, \omega) > u) = 1 - e^{-\int_0^u \lambda_i(y)dy},$$

It follows that for fixed $\omega \in \Omega$ the density of $\tilde{\tau}_i(\omega)$ is given by the function $u \rightarrow e^{-\int_0^u \lambda_i(y)dy}\tilde{\lambda}_i^1(\omega)$. Therefore we have

$$\mathbb{E}^P \left[ 1_{\{s < \tilde{\tau}_i(\omega) \leq t\}} h(\tilde{\tau}_i(\omega), \omega) \right] = \int_t^s h(x, \omega)e^{-\int_t^x \lambda_i(y)dy}\tilde{\lambda}_i^1(\omega)dx$$

for $0 \leq s \leq t \leq T$. \hfill \Box

We start by valuating the payoff payed in case of no default.

**Proposition 6.2.** Let $Y$ be an $\mathcal{F}_T^P$-measurable upper semianalytic function on $\Omega$ such that $\mathcal{E}(Y) < \infty$. Then for every $t \in [0, T]$ the random variables

$$Y e^{-\int_t^T \tilde{\lambda}_i^1 ds}, \quad 1_{(\tau_i > T)} Y,$$

$$Y \left( \int_t^T e^{-\int_t^s \tilde{\lambda}_i^2 ds}e^{-\int_t^s \lambda_i^1 dy}\tilde{\lambda}_i^1 dx + e^{-\int_t^T \tilde{\lambda}_i^2 ds} \right), \quad Y e^{-\int_{T-d}^{T-\tau_i} \tilde{\lambda}_i^2 ds}$$

are upper semianalytic. Moreover, $1_{(\tau_i > T)} Y$ and $1_{(\tau_i > T)} Y$ belong to $L^1(\Omega)$. If $\mathcal{P}$ satisfies Assumption [4.7], we have that

$$\tilde{E}^P_1 \left( 1_{(\tau_i > T)} Y \right) = 1_{(\tau_i > t)} \mathcal{E} \left( Y e^{-\int_t^T \tilde{\lambda}_i^1 ds} \right)$$

(6.3)

and
for every $t \in [0,T]$.

**Proof.** Clearly $1_{\{\tau_1>T\}} Y$ and $Y e^{-\int_0^T \tilde{\lambda}^2_{ds}}$ are upper semianalytic and belong to $L^1(\tilde{\Omega})$. As $1_{\{\tau_1>T\}} Y$ is measurable with respect to $\mathcal{G}^{(1)}$, Proposition 4.4 implies that

$$\tilde{E}^2_t \left(1_{\{\tau_1>T\}} Y \right) = \tilde{E}^1_t \left(1_{\{\tau_1>T\}} Y \right)$$

(6.5)

for all $t \in [0,T]$. Thus (6.3) follows directly by (6.5) and Lemma 2.26 in [5].

By noting that $1_{\{\tau_2>T\}}, e^{\int_0^T \tilde{\lambda}^2_{ds}}, \int_t^T e^{-\int_s^T \tilde{\lambda}^2_{ds}} e^{-\int_s^T \tilde{\lambda}^1_{ds} \, d\tilde{W}_s} e^{-\int_t^T \tilde{\lambda}^1_{ds} \, d\tilde{W}_t}$ and $e^{-\int_{u_1}^T \tilde{\lambda}^2_{ds}}$ are non-negative Borel-measurable functions, it follows by point 4 and 5 in Lemma 4.6 that the random variables

$$1_{\{\tau_2>T\}}, \ Y \left(\int_0^T e^{-\int_0^T \tilde{\lambda}^2_{ds}} e^{-\int_s^T \tilde{\lambda}^1_{ds} \, d\tilde{W}_s} e^{-\int_t^T \tilde{\lambda}^1_{ds} \, d\tilde{W}_t} \right), \ Y e^{-\int_{u_1}^T \tilde{\lambda}^2_{ds}}$$

are upper semianalytic. Moreover, it holds

$$\hat{E}(|Y 1_{\{\tau_2>T\}}|) = \sup_{P \in \mathcal{P}} \mathbb{E}^\hat{P} [|Y 1_{\{\tau_2>T\}}|] \leq \sup_{P \in \mathcal{P}} \mathbb{E}^\hat{P} [|Y|] = \sup_{P \in \mathcal{P}} \mathbb{E}^P [|Y|] = \mathcal{E}(|Y|) < \infty,$$

which proves that $Y 1_{\{\tau_2>T\}}$ is in $L^1(\tilde{\Omega})$. From Definition 4.4 we get

$$\tilde{E}^2_t \left(1_{\{\tau_2>T\}} Y \right) = \tilde{E}_t \left(e^{\int_0^T \tilde{\lambda}^1_{ds} \, d\tilde{W}_t} 1_{\{\tau_1>T\}} \right) + \tilde{E}^1_t \left(e^{\int_{u_1}^T \tilde{\lambda}^2_{ds} \mathbb{E}^P \left[1_{\{\tau_2>T-u_1\}} Y \right]} \right) \bigg|_{u_1=T}$$

(6.6)

for $t \in [0,T]$. It holds

$$\mathbb{E}^\hat{P} \left[1_{\{\tau_1>T\}} 1_{\{\tau_2>T\}} \right] = \mathbb{E}^\hat{P} \left[1_{\{\tau_1>T\}} \right] \mathbb{E}^\hat{P} \left[1_{\{\tau_2>T\}} \right]$$

$$= \mathbb{E}^\hat{P} \left[1_{\{t<T\}} 1_{\{\tau_1>T\}} \right] + \mathbb{E}^\hat{P} \left[1_{\{\tau_1>T\}} 1_{\{\tau_2>T\}} \right]$$

$$= \mathbb{E}^\hat{P} \left[1_{\{t<u_1\}} 1_{\{\tau_2>T-u_1\}} \right] + \mathbb{E}^\hat{P} \left[1_{\{\tau_1>T\}} \right]$$

(6.7)

$$= \mathbb{E}^\hat{P} \left[1_{\{t<u_1\}} e^{-\int_0^T \tilde{\lambda}^2_{ds}} \right] + e^{-\int_0^T \tilde{\lambda}^1_{ds}}$$

$$= \mathbb{E}^\hat{P} \left[1_{\{t<T\}} e^{-\int_0^T \tilde{\lambda}^2_{ds}} \right] + e^{-\int_0^T \tilde{\lambda}^1_{ds}}$$

(6.8)

Here we use Lemma 5.4 in [6,7] and Lemma 6.1 in [6,8] with $h(x,\omega) = e^{-\int_0^t \tilde{\lambda}^2_{ds}}$.

Moreover, for any fixed $u_1 > 0$ and $t \in [0,T]$ we have

$$\mathbb{E}^\hat{P} \left[1_{\{\tau_2>T-u_1\}} \right] = \mathbb{E}^\hat{P} \left[1_{\{\tau_2>T-u_1\}} \right]$$

(6.9)

Then the result follows by putting together (6.5), (6.8) and (6.9).

**Remark 6.3.** By considering non-linear affine processes it is possible to derive a numerical valuation of (6.3), see [4].

We now turn to the case when the default happens before time $T$. We start with the following lemma.
Lemma 6.4. Let $Z := (Z_t)_{t \in [0,T]}$ be an $\mathbb{F}^P$-predictable and non-negative or bounded process on $\Omega$, and fix a measure $\tilde{P} \in \mathcal{P}$ such that $\tilde{P} = P \otimes P$ for a probability measure $P \in \mathcal{P}$. Then we have
\[
\mathbb{E}^\tilde{P} \left[ I_{\{t < \tau_1 \leq s \}} Z_{\tau_1} \mid \mathcal{G}_t^{(2)} \right] = I_{\{t > \tau_1 \}} \mathbb{E}^\tilde{P} \left[ \int_t^s Z_u e^{-\int_t^u \hat{\lambda}_u^1 \, d\lambda_u^1} \, du \mid \mathcal{F}_t \right] \quad \tilde{P}\text{-a.s.} \tag{6.10}
\]
and
\[
\mathbb{E}^\tilde{P} \left[ I_{\{t < \tau_2 \leq s \}} Z_{\tau_2} \mid \mathcal{G}_t^{(2)} \right] = \mathbb{E}^\tilde{P} \left[ I_{\{t > \tau_2 \}} \mathbb{E}^\tilde{P} \left[ \int_t^s \left( \int_0^{s-u} Z_{y+x} e^{-\int_t^y \hat{\lambda}_y^2 \, d\lambda_y^2} \, dx \right) e^{-\int_t^y \hat{\lambda}_y^1 \, d\lambda_y^1} \, dy \mid \mathcal{F}_t \right] \mid \mathcal{G}_t^{(1)} \right] \quad \tilde{P}\text{-a.s.,} \tag{6.11}
\]
for any $0 \leq t \leq s \leq T$.

Proof. Fix $t \in [0,T]$. Equation (6.10) follows as
\[
\mathbb{E}^\tilde{P} \left[ I_{\{t < \tau_1 \leq s \}} Z_{\tau_1} \mid \mathcal{G}_t^{(2)} \right] = \mathbb{E}^\tilde{P} \left[ I_{\{t < \tau_1 \leq s \}} Z_{\tau_1} \mid \mathcal{G}_t^{(1)} \right]
\]
and by Lemma 2.27 in [3]. By Theorem 3.7 it holds
\[
\mathbb{E}^\tilde{P} \left[ I_{\{t < \tau_1 \leq s \}} Z_{\tau_1} \mid \mathcal{G}_t^{(2)} \right] = \mathbb{E}^\tilde{P} \left[ I_{\{t > \tau_1 \}} \mathbb{E}^\tilde{P} \left[ I_{\{t < \tau_1 \leq s \}} Z_{\tau_1} \mid \mathcal{F}_t \right] \mid \mathcal{G}_t^{(1)} \right] \quad (6.12)
\]
We have
\[
\mathbb{E}^P \left[ \mathbb{E}^\tilde{P} \left[ I_{\{t < \tau_1 \leq s \}} Z_{\tau_1} \mid \mathcal{F}_t \right] \right] = \mathbb{E}^P \left[ \mathbb{E}^\tilde{P} \left[ I_{\{t < \tau_1 \leq s \}} Z_{\tau_1} \mid \mathcal{F}_t \right] \right]
\]
and by Lemma 5.4. In addition we use twice Lemma 6.1, namely in (6.14) and (6.15). Analogously we can compute the second term in (6.12) by using (3.24) and Lemma 6.1.

We are now ready to give the following proposition.

Proposition 6.5. Let $Z := (Z_t)_{t \in [0,T]}$ be an $\mathbb{F}^P$-predictable process on $\Omega$ such that the function $Z(t,\omega) := Z_t(\omega)$, $(t,\omega) \in [0,T] \times \Omega$, is upper semianalytic and there exists $M \in \mathbb{R}^+$ such that $\sup_{t \in [0,T]} |Z_t| < M \mathcal{P}$-q.s.. Then for all $0 \leq t \leq s \leq T$ the random variables
\[
I_{\{t < \tau_1 \leq s \}} Z_{\tau_1}, \quad \int_t^s Z_u e^{-\int_t^u \hat{\lambda}_u^1 \, d\lambda_u^1} \, du, \quad I_{\{t < \tau_2 \leq s \}} Z_{\tau_2},
\]
\[
\int_t^s \left( \int_0^{s-u} Z_{y+x} e^{-\int_t^y \hat{\lambda}_y^2 \, d\lambda_y^2} \, dx \right) e^{-\int_t^y \hat{\lambda}_y^1 \, d\lambda_y^1} \, dy, \quad \int_{t-u_1}^{s-u_1} Z_{u_1} e^{-\int_{t-u_1}^u \hat{\lambda}_u^2 \, d\lambda_u^2} \, du
\]

27
Lemma 6.4. for all \( t \) by Proposition 4.9.

derive some sufficient conditions under which the classical tower property holds for such payoffs.

\[
E_t^2 \left( I_{(t < t_1 \leq s)} Z_{t_1} \right) = I_{(t_2 > t)} E_t \left( \int_t^s Z_u e^{- \int_t^u \tilde{\lambda}_u^1 dv} d\tilde{\lambda}_u^1 du \right) \quad \hat{P} \text{-a.s. for all } \hat{P} \in \hat{P} \tag{6.16}
\]

and

\[
E_t^2 \left( I_{(t < t_2 \leq s)} Z_{t_2} \right) = I_{(t_1 > t)} e^{\int_t^{t_1} \tilde{\lambda}_u^1 dv} E_t \left( \int_t^{s-t_1} \left( Z_{y+x} e^{- \int_t^y \tilde{\lambda}_u^2 dw} \tilde{\lambda}_u^2 dw \right) e^{- \int_t^y \tilde{\lambda}_u^1 dw} \tilde{\lambda}_u^1 dw \right)
\]

\[
+ I_{(t_1 \leq t < t_2 \leq s)} e^{d_{t_1} \tilde{\lambda}_u^2 dw} E_t \left( \int_t^{s-t_2} \left( Z_{u_1+x} e^{- \int_t^{u_1+x} \tilde{\lambda}_w^2 dw} \tilde{\lambda}_w^2 dw \right) \right)_{u_1=t_1} \tag{6.17}
\]

\( \hat{P} \text{-a.s. for all } \hat{P} \in \hat{P}, \text{ for all } 0 \leq t \leq T. \)

Proof. Note that \( I_{(t < t_1 \leq s)} Z_{t_1} \) and \( \int_t^s Z_u e^{- \int_t^u \tilde{\lambda}_u^1 dv} \tilde{\lambda}_u^1 dv \) are upper semianalytic and in \( L^1(\hat{\Omega}) \) by Corollary 2.28 in [5]. Equation (6.16) follows by Corollary 2.28 in [5], as

\[
E_t^2 \left( I_{(t < t_1 \leq s)} Z_{t_1} \right) = \tilde{E}_t \left( I_{(t < t_1 \leq s)} Z_{t_1} \right)
\]

by Proposition 4.9.

Points 5 and 6 in Lemma 6.4 imply that

\[
I_{(t < t_2 \leq s)} Z_{t_2}, \int_t^s \left( Z_{y+x} e^{- \int_t^y \tilde{\lambda}_u^2 dw} \tilde{\lambda}_u^2 dw \right) e^{- \int_t^y \tilde{\lambda}_u^1 dw} \tilde{\lambda}_u^1 dw, \int_t^{s-t_2} Z_{u_1+x} e^{- \int_t^{u_1+x} \tilde{\lambda}_w^2 dw} \tilde{\lambda}_w^2 dw
\]

are upper semianalytic. Clearly, \( I_{(t < t_2 \leq s)} Z_{t_2} \) is in \( L^1(\hat{\Omega}) \). Moreover, equation (6.17) follows by Lemma 6.4. \( \square \)

6.1 Sufficient conditions for the classical tower property

In this section we show that the operator \( E_t^2 \) applied to \( \text{CCT}^{(i)} \) maps \( L^1(\hat{\Omega}) \) to \( L^1(\hat{\Omega}) \), and derive some sufficient conditions under which the classical tower property holds for such payoffs.

Proposition 6.6. Let \( Z := (Z_t)_{t \in [0,T]} \) be an \( \mathbb{R}^P \)-predictable non-negative process on \( \Omega \) such that the function \( Z(t, \omega) := Z_t(\omega) \), \((t, \omega) \in [0,T] \times \Omega\), is upper semianalytic and there exists \( M \in \mathbb{R}_+ \) such that \( \sup_{t \in [0,T]} Z_t < M \) \( P \)-a.s. for all \( P \in \mathcal{P} \). If \( \mathcal{P} \) satisfies Assumption 4.1, then we have

\[
E_t^2 \left( I_{(0 < t_2 < t)} Z_{t_2} \right) \in L^1(\hat{\Omega}).
\]

If in addition

\[
\int_t^s E_t \left( \int_{t-x}^{T-x} Z_{x+y} e^{- \int_t^y \tilde{\lambda}_u^2 dw} \tilde{\lambda}_u^2 dw \right) e^{- \int_t^y \tilde{\lambda}_u^1 dw} \tilde{\lambda}_u^1 dw \right) \quad \hat{E}_t \right( \int_t^s \left( \int_{t-x}^{T-x} Z_{x+y} e^{- \int_t^y \tilde{\lambda}_u^2 dw} \tilde{\lambda}_u^2 dw \right) e^{- \int_t^y \tilde{\lambda}_u^1 dw} \tilde{\lambda}_u^1 dw \right) \tag{6.18}
\]

and

\[
\int_t^s E_t \left( \int_{t-x}^{T-x} Z_{x+y} e^{- \int_t^y \tilde{\lambda}_u^2 dw} \tilde{\lambda}_u^2 dw \right) e^{- \int_t^y \tilde{\lambda}_u^1 dw} \tilde{\lambda}_u^1 dw \right) \quad \hat{E}_t \right( \int_t^s \left( \int_{t-x}^{T-x} Z_{x+y} e^{- \int_t^y \tilde{\lambda}_u^2 dw} \tilde{\lambda}_u^2 dw \right) e^{- \int_t^y \tilde{\lambda}_u^1 dw} \tilde{\lambda}_u^1 dw \right) \tag{6.19}
\]

for all \( 0 \leq s \leq t \leq T \), then

\[
E_t^2 \left( E_t^2 \left( I_{(0 < t_2 < t)} Z_{t_2} \right) \right) = E_t^2 \left( I_{(0 < t_2 < t)} Z_{t_2} \right) \quad \hat{P} \text{-a.s. for all } \hat{P} \in \hat{P} \tag{6.20}
\]

for all \( 0 \leq s \leq t \leq T \).
Proof. Let \( t \in [0, T] \). We start by proving that

\[
\mathbb{E} \left( \tilde{E}_t^2 (1_{\{0 < \tau_2 < T\}} Z_{\tau_2}) \right) < \infty. \tag{6.21}
\]

We have

\[
\mathbb{E} \left( \tilde{E}_t^2 (1_{\{0 < \tau_2 < T\}} Z_{\tau_2}) \right) = \sup_{\tilde{P} \in \tilde{P}} \mathbb{E}^{\tilde{P}} \left[ |\tilde{E}_t^2 (1_{\{0 < \tau_2 < T\}} Z_{\tau_2})| \right]
\leq \sup_{\tilde{P} \in \tilde{P}} \mathbb{E}^{\tilde{P}} \left[ \tilde{E}_t^2 (I_{\tau_2}) \right]
\leq \sup_{\tilde{P} \in \tilde{P}} \mathbb{E}^{\tilde{P}} \left[ \tilde{E}_t^2 (M) \right]
= M < \infty. \tag{6.22}
\]

To derive the classical tower property for the payoff function \( 1_{\{0 < \tau_2 < T\}} Z_{\tau_2} \) we need to prove that in this case the inequalities which we use in Section 5 to derive the weak dynamic programming principle are indeed equalities. Let \( 0 \leq s \leq t \leq T \). First, we prove that (5.19) in Lemma 5.6 is indeed an equality, i.e.,

\[
\mathbb{E}^{\tilde{P}} \left[ \mathcal{E}_t \left( 1_{\{s < u \leq t\}} 1_{\{\hat{\tau}_2 > t-u\} E^{f_{t-u} \tilde{\lambda}^2_{du}} \mathbb{E}^{\tilde{P}} \left[ 1_{\{\hat{\tau}_2 > t-u\} 1_{\{0 < u + \hat{\tau}_2 \leq T\}} Z_{u+\hat{\tau}_2} \right] \right) \right]
= \mathcal{E}_t \left( \mathbb{E}^{\tilde{P}} \left[ 1_{\{s < u \leq t\}} 1_{\{\hat{\tau}_2 > t-u\} E^{f_{t-u} \tilde{\lambda}^2_{du}} \mathbb{E}^{\tilde{P}} \left[ 1_{\{\hat{\tau}_2 > t-u\} 1_{\{0 < u + \hat{\tau}_2 \leq T\}} Z_{u+\hat{\tau}_2} \right] \right) \right). \tag{6.23}
\]

By using Lemma 6.4 we can rewrite the left-hand side of (6.23) as

\[
\mathbb{E}^{\tilde{P}} \left[ \mathcal{E}_t \left( 1_{\{s < u \leq t\}} 1_{\{\hat{\tau}_2 > t-u\} E^{f_{t-u} \tilde{\lambda}^2_{du}} \mathbb{E}^{\tilde{P}} \left[ 1_{\{\hat{\tau}_2 > t-u\} 1_{\{0 < u + \hat{\tau}_2 \leq T\}} Z_{u+\hat{\tau}_2} \right] \right) \right]
= \mathbb{E}^{\tilde{P}} \left[ 1_{\{\hat{\tau}_2 > t-u\}} \mathcal{E}_t \left( 1_{\{s < u \leq t\}} E^{f_{t-u} \tilde{\lambda}^2_{du}} \int_{t-u}^{T-u_1} Z_{u_1+v} e^{-f_0 \tilde{\lambda}^2_{du} \tilde{\lambda}_0^2 dv} \right) \right]
= \mathbb{E}^{\tilde{P}} \left[ 1_{\{\hat{\tau}_2 > t-u\}} \mathcal{E}_t \left( 1_{\{s < u \leq t\}} e^{f_{t-u} \hat{\lambda}^2_{du}} \int_{t-u_1}^{T-u_1} Z_{u_1+v} e^{-f_0 \hat{\lambda}^2_{du} \hat{\lambda}_0^2 dv} \right) \right], \tag{6.24}
\]

where (6.24) follows since \( \mathcal{E}_t \left( 1_{\{s < u \leq t\}} E^{f_{t-u} \hat{\lambda}^2_{du}} \int_{t-u}^{T-u_1} Z_{u_1+v} e^{-f_0 \hat{\lambda}^2_{du} \hat{\lambda}_0^2 dv} \right) \) is independent of \( \hat{\omega} \). We now turn to the right-hand side of (6.23). By Lemma 6.1 and similar calculations as for the left-hand side of (6.23), we have that

\[
\mathcal{E}_t \left( \mathbb{E}^{\tilde{P}} \left[ 1_{\{s < u \leq t\}} 1_{\{\hat{\tau}_2 > t-u\} E^{f_{t-u} \hat{\lambda}^2_{du}} \mathbb{E}^{\tilde{P}} \left[ 1_{\{\hat{\tau}_2 > t-u\} 1_{\{0 < u + \hat{\tau}_2 \leq T\}} Z_{u+\hat{\tau}_2} \right] \right) \right]
= \mathcal{E}_t \left( 1_{\{s < u \leq t\}} e^{f_{t-u} \hat{\lambda}^2_{du}} \int_{t-u_1}^{T-u_1} Z_{u_1+v} e^{-f_0 \hat{\lambda}^2_{du} \hat{\lambda}_0^2 dv} \mathbb{E}^{\tilde{P}} \left[ 1_{\{\hat{\tau}_2 > t-u\}} \right) \right]
= \mathcal{E}_t \left( 1_{\{s < u \leq t\}} e^{f_{t-u} \hat{\lambda}^2_{du}} \int_{t-u_1}^{T-u_1} Z_{u_1+v} e^{-f_0 \hat{\lambda}^2_{du} \hat{\lambda}_0^2 dv} \right), \tag{6.26}
\]

At this point, equation (6.23) follows directly by (6.24) and (6.26). Coming now to equation (5.20), from Lemma 6.1 it can be seen that

\[
\mathbb{E}^{\tilde{P}} \left[ \mathcal{E}_t \left( \mathbb{E}^{\tilde{P}} \left[ 1_{\{s < u \leq t\}} 1_{\{\hat{\tau}_2 > t-u\} 1_{\{0 < u + \hat{\tau}_2 \leq T\}} Z_{u+\hat{\tau}_2} \right] \right) \right] \bigg|_{u_1=\tau_1}
= \mathcal{E}_t \left( \mathbb{E}^{\tilde{P}} \left[ 1_{\{s < u \leq t\}} 1_{\{\hat{\tau}_2 > t-u\} 1_{\{0 < u + \hat{\tau}_2 \leq T\}} Z_{u+\hat{\tau}_2} \right] \right) \bigg|_{u_1=\tau_1} \tag{6.27}
\]
is equivalent to

\[
\mathbb{E}^p \left[ \mathbf{1}_{\{s < \tau_2 \leq t\}} \mathcal{E}_t \left( \int_{1-u_1}^{T-u_1} Z_{u_1+v} e^{-f_0^{\alpha} \lambda_0^2 dW_{u_1+v}} \right) \bigg| u_{1}=\tau_1 \right] = \mathcal{E}_t \left( \mathbb{E}^p \left[ \mathbf{1}_{\{s < \tau_1 \}} \mathbf{1}_{\{\tau_1 \leq t < \tau_2 \}} \mathbf{1}_{\{0 < \tau_2 \leq T\}} \mathbb{E}_{\tau_2} \right] \right),
\]

which is exactly condition (6.18) by using Lemma 6.1. Next, we show that the inequalities (6.29) and (6.30) are indeed equalities, i.e.,

\[
\mathbb{E}^p \left[ \mathcal{E}_t \left( \mathbf{1}_{\{s < \tau_1 \}} \mathbf{1}_{\{\tau_2 \leq t\}} \mathbf{1}_{\{0 < \tau_2 \leq T\}} \mathbb{E}_{\tau_2} \right) \right] = \mathcal{E}_t \left( \mathbb{E}^p \left[ \mathbf{1}_{\{s < \tau_1 \}} \mathbf{1}_{\{\tau_1 \leq t < \tau_2 \}} \mathbf{1}_{\{0 < \tau_2 \leq T\}} \mathbb{E}_{\tau_2} \right] \right)
\]

(6.28)

and

\[
\mathcal{E}_t \left( \mathbb{E}^p \left[ \mathbf{1}_{\{s < \tau_1 \}} \mathbf{1}_{\{\tau_1 \leq t < \tau_2 \}} \mathbb{E}_{\tau_2} \right] \right) + \mathcal{E}_t \left( \mathbb{E}^p \left[ \mathbf{1}_{\{s < \tau_1 \}} \mathbf{1}_{\{\tau_1 \leq t < \tau_2 \}} \mathbf{1}_{\{0 < \tau_2 \leq T\}} \mathbb{E}_{\tau_2} \right] \right)
\]

\[
+ \mathcal{E}_t \left( \mathbb{E}^p \left[ \mathbf{1}_{\{s < \tau_1 \}} \mathbf{1}_{\{\tau_1 \leq t < \tau_2 \}} \mathbf{1}_{\{0 < \tau_2 \leq T\}} \mathbb{E}_{\tau_2} \right] \right)
\]

\[
= \mathcal{E}_t \left( \mathbb{E}^p \left[ \mathbf{1}_{\{s < \tau_1 \}} \mathbf{1}_{\{\tau_2 \leq t\}} \mathbf{1}_{\{0 < \tau_2 \leq T\}} \mathbb{E}_{\tau_2} \right] \right) + \mathcal{E}_t \left( \mathbb{E}^p \left[ \mathbf{1}_{\{s < \tau_1 \}} \mathbf{1}_{\{\tau_2 \leq t\}} \mathbf{1}_{\{0 < \tau_2 \leq T\}} \mathbb{E}_{\tau_2} \right] \right)
\]

(6.29)

We first consider the right-hand side of (6.28). Similar arguments used in the derivation of (6.15) imply that

\[
\mathcal{E}_t \left( \mathbb{E}^p \left[ \mathbf{1}_{\{s < \tau_1 \}} \mathbf{1}_{\{\tau_2 \leq t\}} \mathbf{1}_{\{0 < \tau_2 \leq T\}} \mathbb{E}_{\tau_2} \right] \right) = \mathcal{E}_t \left( \mathbb{E}^p \left[ \mathbf{1}_{\{s < \tau_1 \}} \mathbf{1}_{\{\tau_2 \leq t\}} \mathbf{1}_{\{0 < \tau_2 \leq T\}} \mathbb{E}_{\tau_2} \right] \right)
\]

(6.30)

\[
= \int_s^t \left( \int_0^{t-x} Z_{s+x} e^{-f_0^{\alpha} \lambda_0^2 dW_{s+x}} \right) e^{-f_0^{\alpha} \lambda_1^2 d\lambda_1} dx
\]

(6.31)

since \( \int_s^t \left( \int_0^{t-x} Z_{s+x} e^{-f_0^{\alpha} \lambda_0^2 dW_{s+x}} \right) e^{-f_0^{\alpha} \lambda_1^2 d\lambda_1} dx \) is non-negative and \( \mathcal{F}_t \)-measurable.

Moreover, note that for fixed \( \omega \in \Omega \) the random variable \( \mathbf{1}_{\{s < \tau_1 \}} \mathbf{1}_{\{\tau_2 \leq t\}} \mathbf{1}_{\{0 < \tau_2 \leq T\}} \mathbb{E}_{\tau_2} \) is \( \mathcal{F}_t \)-measurable and non-negative. For this reason, the left-hand side of (6.28) can be rewritten as

\[
\mathbb{E}^p \left[ \mathcal{E}_t \left( \mathbf{1}_{\{s < \tau_1 \}} \mathbf{1}_{\{\tau_2 \leq t\}} \mathbf{1}_{\{0 < \tau_2 \leq T\}} \mathbb{E}_{\tau_2} \right) \right] = \mathbb{E}^p \left[ \mathbf{1}_{\{s < \tau_1 \}} \mathbf{1}_{\{\tau_2 \leq t\}} \mathbf{1}_{\{0 < \tau_2 \leq T\}} \mathbb{E}_{\tau_2} \right]
\]

(6.32)

where (6.32) follows by (6.30). We now get (6.28) directly from (6.31) and (6.32).

We now turn to (6.29). The left-hand side terms can be written with similar arguments used as in (6.15) as

\[
\mathbb{E}^p \left[ \mathbf{1}_{\{s < \tau_1 \}} \mathbf{1}_{\{\tau_2 \leq t\}} \mathbf{1}_{\{0 < \tau_2 \leq T\}} \mathbb{E}_{\tau_2} \right] = \int_s^t \left( \int_0^{t-x} Z_{s+x} e^{-f_0^{\alpha} \lambda_0^2 dW_{s+x}} \right) e^{-f_0^{\alpha} \lambda_1^2 d\lambda_1} dx,
\]

(6.33)

\[
\mathbb{E}^p \left[ \mathbf{1}_{\{s < \tau_1 \}} \mathbf{1}_{\{\tau_2 \leq t\}} \mathbf{1}_{\{0 < \tau_2 \leq T\}} \mathbb{E}_{\tau_2} \right] = \int_s^t \left( \int_0^{t-x} Z_{s+x} e^{-f_0^{\alpha} \lambda_0^2 dW_{s+x}} \right) e^{-f_0^{\alpha} \lambda_1^2 d\lambda_1} dx,
\]

(6.34)

and

\[
\mathbb{E}^p \left[ \mathbf{1}_{\{s < \tau_1 \}} \mathbf{1}_{\{\tau_2 \leq t\}} \mathbf{1}_{\{0 < \tau_2 \leq T\}} \mathbb{E}_{\tau_2} \right] = \int_s^t \left( \int_0^{t-x} Z_{s+x} e^{-f_0^{\alpha} \lambda_0^2 dW_{s+x}} \right) e^{-f_0^{\alpha} \lambda_1^2 d\lambda_1} dx.
\]

(6.35)

By (6.31), (6.33), (6.34), (6.35) and assumption (6.19) we get

\[
\mathcal{E}_t \left( \mathbb{E}^p \left[ \mathbf{1}_{\{s < \tau_1 \}} \mathbf{1}_{\{\tau_2 \leq t\}} \mathbb{E}_{\tau_2} \right] \right) + \mathcal{E}_t \left( \mathbb{E}^p \left[ \mathbf{1}_{\{s < \tau_1 \}} \mathbf{1}_{\{\tau_1 \leq t < \tau_2 \}} \mathbf{1}_{\{0 < \tau_2 \leq T\}} \mathbb{E}_{\tau_2} \right] \right)
\]

\[
+ \mathcal{E}_t \left( \mathbb{E}^p \left[ \mathbf{1}_{\{s < \tau_1 \}} \mathbf{1}_{\{\tau_1 \leq t < \tau_2 \}} \mathbf{1}_{\{0 < \tau_2 \leq T\}} \mathbb{E}_{\tau_2} \right] \right)
\]

\[
= \mathcal{E}_t \left( \int_s^T \left( \int_0^{t-x} Z_{s+x} e^{-f_0^{\alpha} \lambda_0^2 dW_{s+x}} \right) e^{-f_0^{\alpha} \lambda_1^2 d\lambda_1} dx \right)
\]

30
\[ + \int_{t-x}^{t} \left( \int_{t-x}^{T-x} Z_{v+x} e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} \right) e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} dx \]

\[ + \int_{0}^{t} \left( \int_{t-x}^{u} Z_{v+x} e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} \right) e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} dx \]

\[ = \mathcal{E}_{t} \left( \int_{t}^{T} \left( \int_{0}^{T-x} Z_{v+x} e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} \right) e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} dx \right) \]

Here, the last equality is implied by the \( \mathcal{F}_{t} \)-measurability of \( \int_{t}^{T} Z_{v+x} e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} dx \). This proves equation (6.29).

In order to conclude the proof, we need to show that inequalities (5.39) and (5.40) in the proof of Proposition 5.38 are indeed equalities, that is,

\[ \mathbb{E}^{\mathcal{P}} \left[ \mathcal{E}_{t} \left( 1 \{ \tau_{2} > s - u_{1} \} 1 \{ u_{1} + \tau_{2} \leq t \} 1 \{ u_{1} + \tau_{2} \leq T \} Z_{u_{1} + \tau_{2}} \right) \right] = \mathcal{E}_{t} \left( \mathbb{E}^{\mathcal{P}} \left[ 1 \{ \tau_{2} > s - u_{1} \} 1 \{ u_{1} + \tau_{2} \leq t \} 1 \{ u_{1} + \tau_{2} \leq T \} Z_{u_{1} + \tau_{2}} \right] \right) \]

(6.36)

and

\[ \mathcal{E}_{t} \left( 1 \{ u_{1} \leq t \} \mathbb{E}^{\mathcal{P}} \left[ 1 \{ \tau_{2} > s - u_{1} \} 1 \{ u_{1} + \tau_{2} \leq T \} Z_{u_{1} + \tau_{2}} \right] \right) + \mathcal{E}_{t} \left( \mathbb{E}^{\mathcal{P}} \left[ 1 \{ \tau_{2} > s - u_{1} \} 1 \{ u_{1} + \tau_{2} \leq t \} 1 \{ u_{1} + \tau_{2} \leq T \} Z_{u_{1} + \tau_{2}} \right] \right) \]

\[ = \mathcal{E}_{t} \left( 1 \{ u_{1} \leq t \} \mathbb{E}^{\mathcal{P}} \left[ 1 \{ \tau_{2} > s - u_{1} \} 1 \{ u_{1} + \tau_{2} \leq T \} Z_{u_{1} + \tau_{2}} \right] \right) + \mathbb{E}^{\mathcal{P}} \left[ 1 \{ \tau_{2} > s - u_{1} \} 1 \{ u_{1} + \tau_{2} \leq t \} 1 \{ u_{1} + \tau_{2} \leq T \} Z_{u_{1} + \tau_{2}} \right] \] .

(6.37)

By Lemma 6.1 we have

\[ \mathcal{E}_{t} \left( \mathbb{E}^{\mathcal{P}} \left[ 1 \{ \tau_{2} > s - u_{1} \} 1 \{ u_{1} + \tau_{2} \leq t \} 1 \{ u_{1} + \tau_{2} \leq T \} Z_{u_{1} + \tau_{2}} \right] \right) = \mathcal{E}_{t} \left( \int_{s-u_{1}}^{u_{1}} Z_{v+u_{1}} e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} \right)
\]

\[ = \int_{s-u_{1}}^{u_{1}} Z_{v+u_{1}} e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} \]

(6.38)

where (6.38) follows since \( \int_{s-u_{1}}^{u_{1}} Z_{v+u_{1}} e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} \) is non-negative and \( \mathcal{F}_{t} \)-measurable. By similar arguments as in (6.34) it follows

\[ \mathbb{E}^{\mathcal{P}} \left[ \mathcal{E}_{t} \left( 1 \{ \tau_{2} > s - u_{1} \} 1 \{ u_{1} + \tau_{2} \leq t \} 1 \{ u_{1} + \tau_{2} \leq T \} Z_{u_{1} + \tau_{2}} \right) \right] = \int_{s-u_{1}}^{u_{1}} Z_{v+u_{1}} e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} \]

(6.39)

which implies together with (6.38) that (6.40) holds. Moreover, by (6.38) and the \( \mathcal{F}_{t} \)-measurability of \( \int_{s-u_{1}}^{u_{1}} Z_{v+u_{1}} e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} \), equation (6.37) follows.

**Example 6.7.** Fix \( 0 \leq s \leq t \leq T \) such that \( T \leq t + s \). Moreover, let the process \( Z = (Z_{t})_{t \in [0,T]} \) be deterministic and non-negative. We want to show that conditions (6.18) and (6.19) are satisfied. Note that

\[ \int_{s}^{t} \left( \int_{t-x}^{T-x} Z_{v+x} e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} \right) e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} dx \]

(6.40)

is \( \mathcal{F}_{t} \)-measurable and non-negative if \( T \leq t + s \). Then we get that

\[ \mathcal{E}_{t} \left( \int_{s}^{t} \left( \int_{t-x}^{T-x} Z_{v+x} e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} \right) e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} dx \right) \]

\[ = \int_{s}^{t} \left( \int_{t-x}^{T-x} Z_{v+x} e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} \right) e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} dx . \]

(6.41)

Moreover, we have

\[ \int_{s}^{t} \mathcal{E}_{t} \left( \int_{t-x}^{T-x} Z_{v+x} e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} \right) e^{-\int_{0}^{v} \lambda_{u}^{2} dw} \frac{\lambda_{u}^{2}}{\lambda_{u}^{2}} dx \]

31
where (6.42) holds because \( \int_{t-u}^{T-u} Z_{u+t} e^{-\int_u^T \lambda_2^2 dv} \lambda_2^2 dv \) is \( \mathcal{F}_t \)-measurable and non-negative for \( \int_{t-u}^{T-u} Z_{u+t} e^{-\int_u^T \lambda_2^2 dv} \lambda_2^2 dv \) is \( \mathcal{F}_t \)-measurable and non-negative for \( \int_{t-u}^{T-u} Z_{u+t} e^{-\int_u^T \lambda_2^2 dv} \lambda_2^2 dv \). Condition (6.18) follows now directly from (6.41) and (6.42). Moreover, since \( \int_t^T \left( \int_0^T x Z_{u+t} e^{-\int_u^T \lambda_2^2 dv} \lambda_2^2 dv \right) e^{-\int_0^u \lambda_1^2 du} \lambda_1^2 du dx \) is \( \mathcal{F}_t \)-measurable, equation (6.44) implies that condition (6.19) holds.

**Proposition 6.8.** Fix \( 0 \leq s \leq t \leq T \) and let \( Y = Y(\omega), \omega \in \Omega, \) be an \( \mathcal{F}_t^T \)-measurable upper semianalytic and non-negative function on \( \Omega \) such that \( E(Y) < \infty. \) If \( \mathcal{P} \) satisfies Assumption 4.1, then \( \tilde{E}_t^2 (1_{[t_2,T]} Y) \in L^1(\Omega) \) for any \( t \in \{0,T\}. \) If in addition

\[
\int_s^t E_t \left( Y e^{-\int_0^{T-t} \lambda_2^2 dv} e^{-\int_0^t \lambda_1^2 du} \lambda_1^2 dx \right) = E_t \left( \int_s^t Y e^{-\int_0^{T-t} \lambda_2^2 dv} e^{-\int_0^t \lambda_1^2 du} \lambda_1^2 dx \right)
\]

(6.43)

and

\[
E_t \left( Y \left( \int_s^t e^{-\int_0^{T-t} \lambda_2^2 dv} e^{-\int_0^t \lambda_1^2 du} \lambda_1^2 dx + e^{-\int_0^t \lambda_1^2 du} \right) \right) + E_t \left( \int_s^t e^{-\int_0^{T-t} \lambda_2^2 dv} e^{-\int_0^t \lambda_1^2 du} \lambda_1^2 dx \right)
\]

(6.44)

then

\[
\tilde{E}_t^2 (1_{[t_2,T]} Y) = \tilde{E}_t^2 (1_{(t_2,T)} Y) \quad \tilde{P}\text{-a.s. for all } \tilde{P} \in \tilde{P}.
\]

(6.45)

**Proof.** To prove this result we have to show that the inequalities (6.19), (6.20), (6.29), (6.30), (5.39) and (5.40) are indeed equalities. This can be done by similar arguments as the ones used in the proof of Proposition 6.8.

We now provide some examples where (6.33) and (6.34) are satisfied.

**Example 6.9.** Let us consider \( Y = 1. \) Assume that \( T \leq t + s, \) which also implies that \( T \leq 2t. \) In this case the left-hand side in (6.43) can be rewritten as

\[
\int_s^t E_t \left( e^{-\int_0^{T-t} \lambda_2^2 dv} e^{-\int_0^t \lambda_1^2 du} \lambda_1^2 dx \right) = \int_s^t e^{-\int_0^{T-t} \lambda_2^2 dv} e^{-\int_0^t \lambda_1^2 du} \lambda_1^2 dx,
\]

(6.46)

since \( e^{-\int_0^{T-t} \lambda_2^2 dv} \) is \( \mathcal{F}_t \)-measurable and non-negative for \( s < x \leq t. \) Note now that

\[
\int_s^t e^{-\int_0^{T-t} \lambda_2^2 dv} e^{-\int_0^t \lambda_1^2 du} \lambda_1^2 dx
\]

is \( \mathcal{F}_t \)-measurable and non-negative. Thus, the right-hand side in (6.43) can be written as

\[
E_t \left( \int_s^t e^{-\int_0^{T-t} \lambda_2^2 dv} e^{-\int_0^t \lambda_1^2 du} \lambda_1^2 dx \right) = \int_s^t e^{-\int_0^{T-t} \lambda_2^2 dv} e^{-\int_0^t \lambda_1^2 du} \lambda_1^2 dx,
\]

(6.47)

so that (6.43) holds by (6.46) and (6.47). Regarding (6.44), we get

\[
E_t \left( \int_s^t e^{-\int_0^{T-t} \lambda_2^2 dv} e^{-\int_0^t \lambda_1^2 du} \lambda_1^2 dx + e^{-\int_0^t \lambda_1^2 du} \lambda_1^2 dx \right) + E_t \left( \int_s^t e^{-\int_0^{T-t} \lambda_2^2 dv} e^{-\int_0^t \lambda_1^2 du} \lambda_1^2 dx \right)
\]

(6.48)

\[
E_t \left( \int_s^t e^{-\int_0^{T-t} \lambda_2^2 dv} e^{-\int_0^t \lambda_1^2 du} \lambda_1^2 dx + e^{-\int_0^t \lambda_1^2 du} \lambda_1^2 dx \right) + \int_s^t e^{-\int_0^{T-t} \lambda_2^2 dv} e^{-\int_0^t \lambda_1^2 du} \lambda_1^2 dx
\]

(6.49)

32
where \( \text{6.48} \) and \( \text{6.49} \) come from \( \text{6.47} \) and from the \( \mathcal{F}_t \)-measurability of the term

\[
\int_s^t e^{-\int_u^t \lambda^2_u du} e^{-\int_0^t \lambda^1_u du} \lambda^1_u dx,
\]

respectively.

**Remark 6.10.**

1. Under the assumption \( T < t + s \), equality \( \text{6.43} \) can also be proved for a general payoff \( Y \) as given in Proposition \( \text{6.3} \) by using the same arguments as in Example \( \text{6.3} \). However, it is not possible to prove \( \text{6.44} \) as the term \( Y \int_s^t e^{-\int_u^t \lambda^2_u du} e^{-\int_0^t \lambda^1_u du} \lambda^1_u dx \) is not any longer \( \mathcal{F}_t \)-measurable. Thus, we have

\[
\mathcal{E}_t \left( Y \int_s^t e^{-\int_u^t \lambda^2_u du} e^{-\int_0^t \lambda^1_u du} \lambda^1_u dx \right) = \mathcal{E}_t \left( Y \int_s^t e^{-\int_u^t \lambda^2_u du} e^{-\int_0^t \lambda^1_u du} \lambda^1_u dx, \right.
\]

which does not allow to do a similar step as in \( \text{6.49} \).

2. In the \( G \)-setting, equality \( \text{6.44} \) holds when

\[
- \mathcal{E}_t \left( -Y \left( \int_s^t e^{-\int_u^t \lambda^2_u du} e^{-\int_0^t \lambda^1_u du} \lambda^1_u dx + e^{-\int_0^t \lambda^1_u du} \right) \right)
\]

\[
= \mathcal{E}_t \left( Y \left( \int_s^t e^{-\int_u^t \lambda^2_u du} e^{-\int_0^t \lambda^1_u du} \lambda^1_u dx + e^{-\int_0^t \lambda^1_u du} \right) \right),
\]

or

\[
- \mathcal{E}_t \left( -Y \int_s^t e^{-\int_u^t \lambda^2_u du} e^{-\int_0^t \lambda^1_u du} \lambda^1_u dx \right) = \mathcal{E}_t \left( Y \int_s^t e^{-\int_u^t \lambda^2_u du} e^{-\int_0^t \lambda^1_u du} \lambda^1_u dx \right).
\]

### 7 Superhedging

By generalizing the superhedging results for payment stream in Section 3 in [5] we can prove also a dynamic robust superhedging duality in our extended setting.

Fix \( T > 0 \). We define the filtration \( \mathcal{G}_t^{\tilde{P},(N)} := (\mathcal{G}_t^{\tilde{P},(N)})_{t \in [0,T]} \) by

\[
\mathcal{G}_t^{\tilde{P},(N)} := \mathcal{G}_t^{(N),*} \vee \mathcal{N}_T^{\tilde{P}}, \quad t \in [0,T],
\]

where \( \mathcal{N}_T^{\tilde{P}} \) is the collection of sets which are \((\tilde{P}, \mathcal{G}_t^{(N)})\)-null for all \( \tilde{P} \in \tilde{P} \). Let \( \tilde{R}_t := (\tilde{R}_t)_{t \in [0,T]} \) be a non-negative \( \mathcal{G}_t^{\tilde{P},(N)} \)-adapted process with nondecreasing paths, such that \( \tilde{R}_t \) is upper semianalytic for all \( t \in [0,T] \) and \( \tilde{R}_0 = 0 \). Moreover, consider a process \( S = (S_t)_{t \in [0,T]} \) which is \( m \)-dimensional, \( \mathcal{G}_t^{\tilde{P},(N)} \)-adapted with càdlàg paths and a \((\tilde{P}, \mathcal{G}_t^{\tilde{P},(N)})\)-semimartingale for all \( \tilde{P} \in \tilde{P} \). Here, \( S \) represents the (discounted) tradable assets on the enlarged market. The money market account is set equal to 1. Furthermore, the set of \( m \)-dimensional \( \mathcal{G}_t^{\tilde{P},(N)} \)-predictable processes which are \( S \)-integrable for all \( \tilde{P} \in \tilde{P} \) is denoted by \( \tilde{L}(S, \tilde{P}) \) and the admissible strategies on \( \tilde{P} \) are given by

\[
\tilde{\Theta} := \left\{ \tilde{d} \in \tilde{L}(S, \tilde{P}) : \int^{(\tilde{P})} \tilde{d} dS \text{ is a } (\tilde{P}, \mathcal{G}_t^{\tilde{P},(N)})\text{-supermartingale for all } \tilde{P} \in \tilde{P} \right\}.
\]

We use the notation \( \int^{(\tilde{P})} \tilde{d} dS := (\int^{(\tilde{P})}_t \tilde{d} dS)_{t \in [0,T]} \) for the usual Itô integral under \( \tilde{P} \).

**Assumption 7.1.**

1. \( \tilde{P} \) is a set of sigma martingale measures for \( S \), i.e., \( S \) is a \((\tilde{P}, \mathcal{G}_t^{\tilde{P},(N)})\)-sigma-martingale for all \( \tilde{P} \in \tilde{P} \);
2. \( \tilde{P} \) is saturated: all equivalent sigma-martingale measures of its elements still belong to \( \tilde{P} \);
3. \( S \) has dominating diffusion under every \( \tilde{P} \in \tilde{P} \).
Next we state generalized versions of Theorem 3.11 and Theorem 3.12 in [5].

**Theorem 7.2.** Let Assumption 4.1 hold for $\mathcal{P}$ and Assumption 7.1 for $\tilde{\mathcal{P}}$, respectively. Consider a cumulative payment stream $\tilde{R} = (R_s)_{s \in [0,T]}$ with $\tilde{E}_s^N(\tilde{R}_T) \in L^1(\Omega)$ for all $s \in [0,T]$. Let $t \in [0,T]$. If there exists a $\tilde{\mathcal{G}}^{P,(N)}$-adapted process $\tilde{X} = (\tilde{X}_s)_{s \in [0,T]}$ with càdlàg paths, such that for $s \in [0,t]$,

$$\tilde{X}_s = \tilde{E}_s^N(\tilde{R}_t) \quad \tilde{P}\text{-a.s. for all } \tilde{P} \in \tilde{\mathcal{P}},$$

and if the tower property holds for $\tilde{R}$, i.e., for all $r, s \in [0,t]$ with $r \leq s$,

$$\tilde{E}_r^N(\tilde{R}_t) = \tilde{E}_r^N(\tilde{E}_s^N(\tilde{R}_t)) \quad \tilde{P}\text{-a.s. for all } \tilde{P} \in \tilde{\mathcal{P}},$$

then we have the following equivalent dualities for all $\tilde{P} \in \tilde{\mathcal{P}}$ and $0 \leq s \leq t \leq T$,

$$\tilde{E}_s^{N}(\tilde{R}_{t}) = \text{ess inf} \tilde{P}\{ \tilde{v} \text{ is } \tilde{\mathcal{G}}^{P,(N)}\text{-measurable : } \exists \tilde{\delta} \in \tilde{\Delta} \text{ such that } \tilde{v} + \int_s^t \tilde{\delta}_u dS_u \geq \tilde{R}_t \} \quad \tilde{P}\text{-a.s.}$$

for all $\tilde{P}' \in \tilde{\mathcal{P}}$ \hspace{1cm} and \hspace{1cm}

$$\tilde{E}_s^{N}(\tilde{R}_t - \tilde{R}_s) = \text{ess inf} \tilde{P}\{ \tilde{v} \text{ is } \tilde{\mathcal{G}}^{P,(N)}\text{-measurable : } \exists \tilde{\delta} \in \tilde{\Delta} \text{ such that } \tilde{v} + \int_s^t \tilde{\delta}_u dS_u \geq \tilde{R}_t - \tilde{R}_s \} \quad \tilde{P}\text{-a.s.}$$

Proof. The proof follows by the same arguments as the proof of Theorem 3.11 in [5].

For $0 \leq s \leq t \leq T$, we define the following set

$$\tilde{C}_s^t : = \left\{ \tilde{\delta} \in \tilde{\Delta} : \tilde{E}_s^{N}(\tilde{R}_t) + \int_{s_1}^{(P)} \tilde{\delta}_u dS_u \geq \tilde{R}_{s_2} \tilde{P}\text{-a.s. for all } \tilde{P} \in \tilde{\mathcal{P}} \text{ for all } s_1 \leq s_2 \leq t \right\}.$$

**Theorem 7.3.** Under the assumptions of Theorem 7.2 for $0 \leq s \leq t \leq T$, we have the following statements:

1. The set $\tilde{C}_s^t$ is not empty.

2. The robust global superhedging price of $\tilde{R}$ is given by $\tilde{E}_s^{N}(\tilde{R}_T)$ and the robust local superhedging price of $\tilde{R}$ on the interval $[s,t]$ is given by $\tilde{E}_s^{N}(\tilde{R}_t - \tilde{R}_s)$.

3. Optimal superhedging strategies exist.

Proof. The proof follows by the same arguments as the proof of Theorem 3.12 in [5].
