Abstract

Background: Stage III unresectable non-small cell lung cancer (NSCLC) is preferably treated with concurrent schedules of chemoradiotherapy, but none is clearly superior. Gemcitabine is a radiosensitizing cytotoxic drug that has been studied in phase 1 and 2 studies in this setting. The aim of this study was to describe outcome and toxicity of low-dose weekly gemcitabine combined with concurrent 3-dimensional conformal radiotherapy (3D-CRT).

Patients & methods: Treatment consisted of two cycles of a cisplatin and gemcitabine followed by weekly gemcitabine 300 mg/m² during 5 weeks of 3D-CRT, 60 Gy in 5 weeks (hypofractionated-accelerated). Overall survival (OS), progression-free survival (PFS), and treatment related toxicity according to Common Toxicity Criteria of Adverse Events (CTCAE) version 3.0 were assessed.

Results: Between February 2002 and August 2008, 318 patients were treated. Median age was 64 years (range 36–86); 72% were male, WHO PS 0/1/2 was 44/53/3%. Median PFS was 15.5 months (95% confidence interval [CI], 12.9-18.1) and median OS was 24.6 months (95% CI, 21.0-28.1). Main toxicity (CTCAE grade ≥3) was dysphagia (12.6%), esophagitis (9.6%), followed by radiation pneumonitis (3.0%). There were five treatment related deaths (1.6%), two due to esophagitis and three due to radiation pneumonitis.

Conclusion: Concurrent low-dose gemcitabine and 3D-CRT provides a comparable survival and toxicity profile to other available treatment schemes for unresectable stage III.

Keywords: Gemcitabine, Stage III NSCLC, Radiotherapy, Concurrent chemoradiotherapy

Introduction

At presentation approximately 30% of patients with non-small-cell lung cancer (NSCLC) have locally advanced (stage III) disease [1]. Median overall survival for clinically staged NSCLC stage IIIA is 14 months and for stage IIIB 10 months with five-year survival of 19% and 7%, respectively [2]. For good performance patients with unresectable stage III disease, the treatment of choice is concurrent chemoradiotherapy [3,4]. Different treatment modalities are used in practice, but none is clearly superior to others [5-11].

Gemcitabine is among the strongest radiosensitizing drugs available, but its use in lung cancer has been limited due to substantial toxicity when combining full-dose gemcitabine with radiotherapy in treatment of stage III NSCLC [12,13]. Excess rates of radiation pneumonitis have been reported using gemcitabine in chemoradiation for lung cancer in earlier studies that had used 2D radiotherapy [14,15]. Previously, a phase I trial was conducted at our institution establishing a safe schedule of concurrent weekly 300 mg/m² gemcitabine and 3D-CRT [16]. These results were confirmed in a phase II trial at our institution [17].

Here we report survival time and treatment related toxicity of this treatment regimen in a consecutive cohort of patients receiving gemcitabine-based concurrent chemoradiotherapy for stage III unresectable NSCLC over a period of 7 years. A subgroup analysis of patients aged >70 years was planned a priori.

**Materials and methods**

**Patient selection**

From February 2002 until December 2009, consecutive patients with stage III unresectable NSCLC who were treated with concurrent chemoradiotherapy with gemcitabine as radiosensitizer referred to one radiotherapy department from 6 hospitals in the northern part of the Netherlands were studied. Staging was performed by whole body \(^{18}\)F-FDG-PET, contrast enhanced chest CT, bronchoscopy, endoscopic ultrasound with fine-needle biopsy and mediastinoscopy. Treatment-related decisions were made during the weekly multidisciplinary meetings. The decision for treating these patients with this scheme, which was regarded as the standard treatment protocol for NSCLC stage III, was based on physical condition (performance status according to WHO), co-morbidity, and expected radiotherapy dose–volume constraints.

**Induction chemotherapy**

Chemotherapy consisted of two cycles of cisplatin 75 mg/m\(^2\) on day 1 and gemcitabine 1125 mg/m\(^2\) administered intravenously on day 1 and 8 of each 21-day cycle. This dose of gemcitabine provides the same dose intensity as the older 3 out of 4 week schedule. Antiemetics were ondansetron 8 mg twice daily on days 1 and 2, and dexamethasone 8 mg twice a day on days 1 and 2 of each cycle and aprepitant 125 mg on day 1 and 80 mg on days 2 and 3. The interval between the first dose of induction chemotherapy and the start of radiotherapy was 6 weeks.

**Radiotherapy with gemcitabine as sensitizer**

Patients received 3D-CRT to a total dose of 60 Gy, administered over 5 weeks in once daily fractions of 2.4 Gy five days per week, together with once weekly gemcitabine 300 mg/m\(^2\). Gemcitabine was omitted when leukocytes were below 3.10\(^9\)/L or platelets below 100.10\(^9\)/L. The gross target volume (GTV) was delineated on the planning-CT and included the primary tumor and enlarged FDG-avid, or pathologically proven lymph nodes. Until 2005, tumor motion was determined with fluoroscopy and respective margins were added to the GTV, thereafter, an internal target volume (ITV) was individually delineated using a 4D-planning CT. A 5 mm margin was added to arrive at the clinical target volume, another 6 mm were added for the planning target volume (PTV). Radiotherapy was delivered using 6 MV photons, the dose was specified at the isocenter and was corrected for pulmonary heterogeneity. The total radiation dose administered corresponded to an equivalent dose of 62 Gy if it were given in 2 Gy daily fractions.

**Dose constraints**

The spinal cord dose was constrained to 50 Gy. The mean lung dose (MLD) should not exceed 20 Gy (uncorrected for the slightly higher dose per fraction; this would equal 21.6 Gy converted to 2Gy/fraction equivalent dose using an alpha/beta of 3Gy in the linear quadratic formula). The \(V_{20}\) (the volume of the total lung volume receiving \(\geq 20\) Gy) was constrained to 30\% (this value is challenging to recalculate using the linear-quadratic formula, but will correspond to a value about 8\% higher if given in 2Gy daily fractions).

For patients with high-volume disease, a proof-planning was made and evaluated for feasibility by the radiation oncologist. If necessary, the radiation dose was adapted. If the pulmonary dose constraints were still considerably exceeded after radiation dose reduction, patients were excluded from this protocol.

**Treatment evaluation**

Complete blood cell counts were performed on days 1, 8, and 22 of each induction chemotherapy cycle. On day 1 of each cycle, patient evaluation also included liver and renal functions, performance status, and toxicity scoring. During radiotherapy, complete blood cell counts and toxicity evaluation were performed. Two months after completion of treatment a response CT scan was obtained and patients were followed every 3 months with physical examination, laboratory tests and chest x-ray. Disease progression was defined according to RECIST 1.0 criteria [18]. Toxicity (esophagitis, and radiation pneumonitis) related to treatment was retrospectively scored using the Common Toxicity Criteria (CTCAE 3.0) of the National Cancer Institute.

**Statistical analysis**

Descriptive statistics were used to characterize clinical features and toxicity. Using the Kaplan-Meier method, overall survival (OS) and progression-free survival (PFS) were calculated from the date of diagnosis until death, loss to follow-up, or first documentation of progressive disease, respectively. A subgroup analysis in patients aged over 70 years was performed to evaluate the outcome in elderly patients. Cox regression analysis was performed with the variables age, smoking, gender, histology, radiation dose, WHO performance score and PT. A p-value of < 0.05 was considered statistically significant. All calculations were performed using SPSS 2.0 (International Business Machines Corp, Armonk, NY, USA).
Results

Three hundred and eighteen subsequent patients receiving concurrent chemoradiotherapy with gemcitabine as a radiosensitizer were studied. Median age was 64 years (range 36–86); male/female was 72/28%; WHO PS 0/1/2 was 44, 53 and 3%. A total of 93 patients were aged ≥ 70.

Chemotherapy

Two hundred and forty-two patients (76%) received cisplatin and gemcitabine as induction, 42 (13%) received carboplatin and gemcitabine, and 9 patients (3%) received other schedules. Twenty five (8%) patients did not receive induction chemotherapy. A total of 259 patients (81%) received all 5 weekly doses of gemcitabine during radiotherapy, 244 (76%) received both full dose gemcitabine and full dose radiotherapy. Fifty-one patients (16%) received between 1 and 4 gemcitabine administrations weekly, mainly due to neutropenia and thrombocytopenia. For the remaining 8, no information was available. Patient characteristics are detailed in Table 1. Interestingly, advanced age did not lead to decreasing the concomitant gemcitabine dose (Table 2).

Seven patients (2%) had a tumor resection after chemoradiotherapy.

Radiotherapy

The radiotherapy dose was 60 Gy in 284 patients (89%) while less than 60 Gy (range, 29 to 58 Gy) was administered in 34 patients (11%). These 34 patients included 17 patients with increased risk of radiation pneumonitis due to increased V20 and 8 patients who stopped treatment due to radiation related toxicity including 3 patients with CTC grade 3 esophagitis. Nine patients received less than 60 Gy for undocumented reasons.

The median PTV was 431 cc with the 90th percentile at 734 cc. Median V20 was 22.7% and the 90th percentile was 31.0%. In patients aged ≥ 70, median PTV was not different at 411 cc with the 90th percentile at 702 cc. Median V20 was 23%, with the 90th percentile at 30.6%.

Survival

Median PFS was 15.5 months (95% CI, 12.9-18.1) (Figure 1a) and median OS was 24.6 months (95% CI, 21.0-28.1) with a 5-year survival of 26% (Figure 1b). In the 244 patients who completed full concurrent treatment, median survival was 26.3 months (95% CI, 21.9-30.6 months) with a 5-year survival of 27%. In patients aged ≥ 70, median PFS was 18.7 (95% CI, 10.0-27.4) and OS was 26.2 months (95% CI, 19.0-33.4) with a 19% 5 year survival rate.

Using univariate Cox analysis, current smoking at diagnosis, squamous cell histology, higher WHO performance score, male gender and larger PTV, were all identified as negative factors influencing survival.

Table 1 Patient characteristics

| Number of patients | (N = 318) | % |
|--------------------|-----------|---|
| Age 64 (36–86)    | 229/89    | 72/28 |
| WHO 0 129 44      | 151 53    | 2 3  |
| 1 151 53          | 10 3      |
| 2 10 3            |
| Unknown 28        |
| Histology         |
| Adenocarcinoma 68 | 157 49.4  |
| Squamous cell 157 | 93 29.2   |

| Former 109        | 34 34     |
| Unknown 37        | 12 12     |
| Induction treatment |
| Cisplatin/gemcitabine 242 | 76 |
| Carboplatin/gemcitabine 42 | 13 |
| Platinum/pemetrexed 4 | 1 |
| Other 5           | 2 2       |
| No induction 25    | 8 8       |
| Radiotherapy dose received |
| 30-59 Gy 34       | 11 11     |
| 60 Gy 284         | 89 89     |
| >60 Gy 0          | 0 0       |
| During chemoradiotherapy: Received 5 gemcitabine cycles and 60 Gy 244 | 76 |
| Received 1–4 gemcitabine cycles and/or received less then 60 Gy 74 | 24 |

Table 2 Number of cycles of weekly gemcitabine with respect to age in stage III NSCLC

| Age | Number of patients |
|-----|--------------------|
| Age < 70 | 1 (≤1%) | 0 | 1 (≤1%) |
| Age ≥ 70 | 7 (3%) | 3 (3%) | 10 (3%) |
| 2     | 9 (4%) | 7 (8%) | 16 (5%) |
| 3     | 13 (6%) | 11 (12%) | 24 (8%) |
| 4     | 188 (84%) | 71 (76%) | 259 (84%) |

From 8 patients the weekly gemcitabine dosage was not specified.
multivariate Cox analysis, current smoking, male gender and larger PTV remained as negative factors influencing survival.

Toxicity
Most common toxicities were CTC grade 2 esophagitis (13.6%), and CTC grade 2 radiation pneumonitis (17.7%)

Figure 1 Survival of 318 patients treated with gemcitabine and 3D concurrent radiotherapy. a. Median Progression Free Survival was 15.5 months (95% CI, 12.9-18.1). b. Median Overall Survival was 24.6 months (95% CI, 21.0-28.1) with a 5-year survival of 26%.
Radiation pneumonitis was also in the same range as other recent studies. In addition, esophageal toxicity and radiation pneumonitis was also reported in our patients. For instance, in a study from Blanco et al., drug dosage was adapted due to toxicity while other studies have been closed due to unacceptable toxicity profiles (especially pulmonary toxicity) [15,22,23]. Price et al. investigated gemcitabine at a lower dosage (100 mg/m²) combined with a lower radiation dosage (55 Gy) given in a shorter time span (4 weeks) in a study that was prematurely closed due to slow accrual. There were 2 deaths in the gemcitabine arm due to acceleration of pre-existing interstitial lung disease [24]. Of note, in that study a daily fraction-dose of 2.75 Gy was given and the lung-dose-constraints had not been adapted for this higher dose per fraction. To our knowledge, there are no further reports using hypofractionated accelerated radiotherapy combined with gemcitabine.

The main factors that are important concerning pulmonary toxicity (i.e. radiation pneumonitis) during chemoradiation with concurrent low-dose gemcitabine are not completely understood. Lung dose, the use of conformal radiotherapy and the timing of the gemcitabine dosage are primary candidates. The CALGB 30105 trial showed that a V$_{20}$ of 40% was associated with significant grade 3–5 pulmonary toxicity [25], which would be expected with any other combination treatment, even with radiotherapy alone. We observed no unexpected pulmonary toxicity rates, because at our institute, the constraint for V$_{20}$ was set at a rather conservative 30% (uncorrected for the slightly higher daily fraction dose of 2.4 Gy) and indeed the vast majority (90%) of treated patients had a V$_{20}$ lower than 30%. Elective nodal irradiation was completely foregone in the first year of this study, with no ensuing statistically significant toxicity differences. However, all three patients in our study who died due to radiation pneumonitis were aged above 70 – and had V$_{20}$ of 16, 34 and 30%, respectively. The CALGB study also identified older age to be associated with increased pulmonary toxicity [25].

Also for esophageal toxicity, radiation technique had been shown to be critical. In a phase 1 study, which initially started using 2D conformal techniques, but halfway switched to 3D techniques, the percentage of the esophagus irradiated to 60 Gy dropped from 68 to 18%, and grade 2 esophagitis dropped from 5/10 patients to 2/14 patients [14].

Administration of gemcitabine more frequently than once weekly was also associated with increased toxicity.
One study administered gemcitabine twice weekly (50 mg/m²) with 3D radiotherapy with elective nodal irradiation of the mediastinum [22]. Of note, the PTVs in that study were three times as large as ours due to elective nodal irradiation. Due to unacceptable toxicity, the gemcitabine dose was reduced to 35 mg/m², but even after this reduction, still more severe CTC grade ≥ 3 esophageal and pulmonary toxicity was observed compared to our study. Our once weekly schedule featured 3 (for 50 mg/ m²) to 4.3 times (for 35 mg/ m²) the cumulative weekly gemcitabine dose [22]. This suggests that timing of drug administration may trigger toxicity, as was also demonstrated in our previous phase 1 and 2 clinical trials.

There were a total of 5 (1.6%) non-hematological grade 5 events in our study, which is comparable to other mainstream treatment regimens [6,7,10,20].

Conclusions

Treatment of patients with unresectable stage III NSCLC with cisplatin and gemcitabine followed by concurrent gemcitabine and 3D conformal radiotherapy was safe and yielded effectiveness and toxicity rates comparable with other drugs in our hands. These results are very likely due to conservative radiation dose-constraints and 3D-conformal radiotherapy avoiding irradiation of excessive volumes of uninvolved mediastinal areas. Although age was not a factor influencing survival and the absolute incidence at 3% grade 5 pneumonitis in patients older than 70 years was what could be expected, patients above 70 years of age should be selected with great caution for this regimen.

Competing interest

Through H.J.M.G., the hospital receives research grants from Eli Lilly, Pfizer and Roche. All remaining authors have declared no conflicts of interest.

Authors’ contribution

Study concept and design was done by LFAD, EMW, TJNH and HJMG. Data acquisition was done by GSMAK, LFAD, EMW, JW, EB, EMD, JWWG, JWIL, TEJR, RMP, MJFM. Quality control and assurance was done by EMW, JW and EB. Data analysis, interpretation and statistical analysis was done by GSMAK, JW and HG. Manuscript preparation was done by GSMAK and HJMG. Editing and review was done by LFAD, EMW, JW, EB, EMD, JWWG, JWIL, TEJR, RMP, MJFM and TJNH. All authors attest to its validity and legitimacy of the presented facts and agree to its submission.
