Abstract

The star chromatic index of a graph $G$ is the smallest integer $k$ for which $G$ admits a proper edge coloring with $k$ colors such that there is no bicolored path nor cycle of length four. In this paper, we first obtain an upper bound for the star chromatic index of the Cartesian product of two graphs. We then determine the exact value of the star chromatic index of 2-dimensional grids. We also obtain upper bounds on the star chromatic index of the Cartesian product of a path with a cycle, $d$-dimensional grids, $d$-dimensional hypercubes and $d$-dimensional toroidal grids, for every natural number $d \geq 2$.

1 Introduction

Here we briefly introduce the graph theory terminology and notations that we need throughout the paper. All graphs considered in this paper are finite, simple and undirected. We use $P_n$ and $C_n$ to denote a path and a cycle of order $n$, respectively. A path (cycle) of length $k$ (i.e. with $k$ edges) is referred to as a $k$-path ($k$-cycle). Let $G$ be a graph with vertex set $V(G)$ and edge set $E(G)$. The number of edges that are incident to a specific vertex in $G$ is called the degree of that vertex. The maximum degree of $G$, denoted by $\Delta(G)$ or simply $\Delta$, is the maximum degree among all the vertices in $G$. The distance between two edges in $G$ is the minimum length of the paths between every two end-points of these edges. A subset $M$ of edges in $G$ is called a matching if every two edges in $M$ have no common end-point. A perfect matching is a matching which covers all vertices of $G$.

The Cartesian product of two graphs $G$ and $H$, denoted by $G \square H$, is a graph with vertex set $V(G) \times V(H)$, and $(a, x)(b, y) \in E(G \square H)$ if either $ab \in E(G)$ and

* Research is partially supported by the Iran National Science Foundation (INSF).
$x = y$, or $xy \in E(H)$ and $a = b$. For a natural number $d$, we denote by $G^d$ the $d$-th Cartesian power, that is $G^d = G$ when $d = 1$, and $G^d = G^{d-1} \square G$ when $d > 1$. A $d$-dimensional hypercube $Q_d$ is the $d$-th Cartesian power of $P_2$. A $d$-dimensional grid $G_{\ell_1, \ell_2, \ldots, \ell_d} = P_{\ell_1} \square P_{\ell_2} \square \ldots \square P_{\ell_d}$ is the Cartesian product of $d$ paths. A $d$-dimensional toroidal grid $T_{\ell_1, \ell_2, \ldots, \ell_d} = C_{\ell_1} \square C_{\ell_2} \square \ldots \square C_{\ell_d}$ is the Cartesian product of $d$ cycles.

A proper vertex (respectively edge) coloring of graph $G$ is an assignment of colors to the vertices (respectively edges) of $G$ such that no two adjacent vertices (respectively two incident edges) receive the same color. The minimum number of colors that is needed to properly color the vertices (respectively edges) of $G$ is called the chromatic number (respectively chromatic index) of $G$, and is denoted by $\chi(G)$ (respectively $\chi'(G)$). A star vertex coloring of $G$, is a proper vertex coloring of $G$ such that no path or cycle on four vertices in $G$ is bi-colored (see [3,5]).

In 2008, Liu and Deng [7] introduced the edge version of the star vertex coloring that is defined as follows. A star edge coloring of $G$ is a proper edge coloring of $G$ such that no path or cycle of length four in $G$ is bi-colored. We call a star edge coloring of $G$ with $k$ colors, a $k$-star edge coloring of $G$. The smallest integer $k$ for which $G$ admits a $k$-star edge coloring is called the star chromatic index of $G$ and is denoted by $\chi'_s(G)$. Liu and Deng [7] presented an upper bound of $\lceil 16(\Delta - 1)^2 \rceil$ for the star chromatic index of graphs with $\Delta \geq 7$. In [2], Dvořák et al. obtained the lower bound $2\Delta(1 + o(1))$ and the near-linear upper bound $\Delta \cdot 2^{O(1) \sqrt{\log \Delta}}$ for the star chromatic index of graphs. They also presented some upper bounds and lower bounds for the star chromatic index of complete graphs and subcubic graphs (graphs with maximum degree at most 3). In [1], Bezegová et al. obtained some bounds on the star chromatic index of subcubic outerplanar graphs, trees and outerplanar graphs. Some other results on the star chromatic index of graphs can be found in [6,8,10–12].

This paper is organized as follows. In Section 2, we give a tight upper bound for the star chromatic index of the Cartesian product of two arbitrary graphs $G$ and $H$. In Section 3, we determine the exact value of $\chi'_s(P_m \square P_n)$ for all natural numbers $m, n \geq 2$. Then, we give some upper bounds for the star chromatic index of the Cartesian product of a path and a cycle and the Cartesian product of two cycles. Moreover, applying the upper bounds obtained in Section 2, we give upper bounds on the star chromatic index of grids, hypercubes, and toroidal grids.

2 General upper bounds

In this section, we define the concept of star compatibility and use this concept to obtain an upper bound for the star chromatic index of the Cartesian product of two graphs. Naturally, these bounds imply some upper bounds on the star chromatic index of $G \square P_n$ and $G \square C_n$, for every graph $G$.

Let $f$ be a star edge coloring of a graph $G$. For every vertex $v$ of $G$, we denote the set of colors of the edges incident to $v$ by $C_f(v)$. Two star edge colorings $f_1$ and
$f_2$ of $G$ are star compatible if for every vertex $v$, $C_{f_1}(v) \cap C_{f_2}(v) = \emptyset$. We say that graph $G$ is $(k, t)$-star colorable if $G$ has $t$ pairwise star compatible colorings with $k$ colors.

**Theorem 2.1.** If $G$ and $H$ are two graphs such that $G$ is $(k_G, t_G)$-star colorable and $t_G \geq \chi(H)$, then 
\[
\chi_s'(G \Box H) \leq k_G + \chi_s'(H).
\]
Moreover, this bound is tight.

**Proof.** Let $f_i : E(G) \to \{0, 1, \ldots, k_G - 1\}$, $0 \leq i \leq t_G - 1$, be star compatible colorings of $G$ and $f_H : E(H) \to \{k_G, k_G + 1, \ldots, k_G + \chi_s'(H) - 1\}$ be a star edge coloring of $H$. Also, let $E_H$ be a proper vertex coloring of $H$ using colors $\{0, 1, \ldots, \chi(H) - 1\}$. We define edge coloring $f$ of $G \Box H$ as follows. For every edge $ab$ of $G$ and every vertex $x$ of $H$, let 
\[
f((a, x) \cdot (b, x)) = f_{E_H(x)}(ab),
\]
that is well-defined, since $t_G \geq \chi(H)$.

For every edge $xy$ of $H$ and every vertex $a$ of $G$, let 
\[
f((a, x) \cdot (a, y)) = f_H(xy).
\]
Note that edge coloring $f$ uses $k_G + \chi_s'(H)$ different colors. Since the colors of edges in $G$ and $H$ are different and colorings $f_H$ and $f_i$, $0 \leq i \leq t_G - 1$, are star edge colorings, the edge coloring $f$ is a proper edge coloring and every 4-path (or 4-cycle) with two incident edges in $G$ or $H$ uses at least three different colors. Thus, we only need to consider the case where we have a path with edges $\alpha = (a, x)(b, x)$, $\beta = (b, x)(b, y)$ and $\gamma = (b, y)(c, y)$, respectively. In such a case, we have $f(\alpha) = f_{E_H(x)}(ab)$ and $f(\gamma) = f_{E_H(y)}(bc)$. On the other hand, $c_H(x) \neq c_H(y)$ because $xy \in E(H)$, and consequently star edge colorings $f_{E_H(x)}$ and $f_{E_H(y)}$ are star compatible. Therefore, $f(\alpha) \neq f(\gamma)$. This shows that $f$ is a star edge coloring of $G \Box H$.

Now, we prove the tightness of the bound. Let $G \cong P_2$ and $H \cong C_n$, where $n > 4$ is even. Note that for paths and cycles, there exists a star edge coloring with at most 3 colors except for $C_5$ which requires 4 colors (see proof of Theorem 5.1 in [2]). Therefore, since $\chi_s'(C_n) = 3$ and $P_2$ is $(2, 2)$-star colorable, we conclude that $\chi_s'(P_2 \Box C_n) \leq 5$. Up to symmetry and permutation, there are only four different 4-star edge colorings of $P_2 \Box P_3$ that are shown in Figure 1. It is easy to check that none of the colorings can be extended to a 4-star edge coloring of $P_2 \Box C_n$. Hence, for every $n \geq 5$, $\chi_s'(P_2 \Box C_n) \geq 5$, which implies the bound is tight. 

Note that if $G$ is a $(k_G, t_G)$-star colorable graph, then it is also $(ak_G, at_G)$-star colorable for natural number $a$. In particular, every graph $G$ is $(\alpha \chi_s'(G), a)$-star colorable and therefore, $G$ is $((\chi_s'(G)(\chi(H)), \chi(H))$-star colorable, for every graph $H$. Thus, using Theorem 2.1, we have the following corollary.
Corollary 2.1. For every two graphs $G$ and $H$, we have

$$
\chi'_s(G \square H) = \chi'_s(H \square G) \leq \min\{\chi'_s(G)\chi(H) + \chi'_s(H)\chi(G) + \chi'_s(G)\}.
$$

In the following theorem we obtain star compatible colorings for the Cartesian product of two graphs.

Theorem 2.2. Let $G$ be $(k_G, t_G)$-star colorable graph and let $H$ be $(k_H, t_H)$-star colorable graph. If $t_G \geq \chi(H)$ and $t_H \geq \chi(G)$, then $G \square H$ is $(k_G + k_H, \min\{t_G, t_H\})$-star colorable.

Proof. Suppose that $g_i : E(G) \rightarrow \{0, 1, \ldots, k_G - 1\}$, $0 \leq i \leq t_G - 1$, are star compatible colorings of $G$ and $h_i : E(H) \rightarrow \{k_G, k_G + 1, \ldots, k_G + k_H - 1\}$, $0 \leq i \leq t_H - 1$, are star compatible colorings of $H$. Also, let $c_G : V(G) \rightarrow \{0, 1, \ldots, \chi(G) - 1\}$ be a proper vertex coloring of $G$ and $c_H : V(H) \rightarrow \{0, 1, \ldots, \chi(H) - 1\}$ be a proper vertex coloring of $H$. If $t = \min\{t_G, t_H\}$, then for each $0 \leq i \leq t - 1$, we define edge coloring $f_i$ of $G \square H$ as follows. For every edge $ab$ of $G$ and for every vertex $x$ of $H$, let $m_i(x) = (c_H(x) + i) \mod t_G$ and

$$f_i((a, x)(b, x)) = g_{m_i(x)}(ab).
$$

Also, for every edge $xy$ of $H$ and for every vertex $a$ of $G$, let $n_i(a) = (c_G(a) + i) \mod t_H$ and

$$f_i((a, x)(a, y)) = h_{n_i(a)}(xy).
$$

By the same argument as in proof of Theorem 2.1, every $f_i$, $0 \leq i \leq t - 1$, is a star edge colorings of $G \square H$. It suffices to prove that edge colorings $f_1, \ldots, f_{t-1}$ are pairwise compatible as follows. For each vertex $(a, x)$, consider colorings $f_i$ and $f_j$, where $0 \leq i < j \leq t - 1$. We can easily see that

$$C_{f_i}((a, x)) = C_{g_{m_i(x)}}(a) \cup C_{h_{n_i(a)}}(x),$$

and

$$C_{f_j}((a, x)) = C_{g_{m_j(x)}}(a) \cup C_{h_{n_j(a)}}(x).$$

Also, for $i \neq j$, we have $m_i(x) \neq m_j(x)$ and $n_i(a) \neq n_j(a)$. Therefore, $C_{g_{m_i(x)}}(a) \cap C_{g_{m_j(x)}}(a) = \emptyset$ and $C_{h_{n_i(a)}}(x) \cap C_{h_{n_j(a)}}(x) = \emptyset$. Moreover, since the star edge colorings of $G$ and $H$ use different sets of colors, $C_{g_{m_i(x)}}(a) \cap C_{h_{n_j(a)}}(x) = \emptyset$ and $C_{g_{m_j(x)}}(a) \cap C_{h_{n_i(a)}}(x) = \emptyset$. Thus, we conclude that $C_{f_i}((a, x)) \cap C_{f_j}((a, x)) = \emptyset$, as desired. \hfill \Box
Corollary 2.2. If $G$ is a $(k_G, t_G)$-star colorable graph and $t_G \geq \chi(G)$, then $G^d$ is $(d \cdot k_G, t_G)$-star colorable.

Proof. If $d = 2$, then by Theorem 2.2, graph $G^2$ is $(2k_G, t_G)$-star colorable. Now, suppose that $d > 2$ and $G^{d-1}$ is $((d-1) \cdot k_G, t_G)$-star colorable. Then using Theorem 2.2 and by induction on $d$, we conclude that $G^d = G^{d-1} \Box G$ is $(d \cdot k_G, t_G)$-star colorable. □

In order to study the star chromatic index of the Cartesian product of paths and cycles with an arbitrary graph, in the following theorems we present some star compatible colorings of paths and cycles.

Theorem 2.3. For all natural numbers $n, r \geq 2$, $P_n$ is $(2r, r)$-star colorable.

Proof. Let $V(P_n) = \{0, 1, \ldots, n-1\}$ and $E(P_n) = \{xy : 0 \leq x \leq n-2, y = x+1\}$. We define edge colorings $f_i : E(P_n) \to \{0, 1, \ldots, 2r-1\}$, $0 \leq i \leq r-1$, as follows. For each $xy \in E(P_n)$ with $x < y$, let $f_i(xy) = x + 2i \pmod{2r}$.

Clearly, each $f_i$, $0 \leq i \leq r-1$, is a star edge colorings of $P_n$. For every $i$ and $j$, $0 \leq i < j \leq r-1$, and every $x \in V(P_n)$, we have

$$C_{f_i}(x) \cap C_{f_j}(x) = \begin{cases} \{2i\} \cap \{2j\} & \text{if } x = 0, \\
\{x-1+2i, x+2i\} \cap \{x-1+2j, x+2j\} & \text{if } 0 < x < n-1, \\
\{n-2+2i\} \cap \{n-2+2j\} & \text{if } x = n-1.
\end{cases}$$

Since $0 \leq i < j \leq r-1$, $2i \neq 2j \pmod{2r}$. Therefore, $C_{f_i}(x) \cap C_{f_j}(x) = \emptyset$, and consequently edge colorings $f_i$ and $f_j$ are pairwise star compatible. □

Theorem 2.4. For all natural numbers $n, r \geq 2$, we have the following statements.

(i) If $n \geq 4$ is even, then $C_n$ is $(2r, r)$-star colorable.

(ii) If $n \geq 2r + 1$ is odd, then $C_n$ is $(2r + 1, r)$-star colorable.

(iii) If $n \geq 3$ is odd, then $C_n$ is $(2r + \lceil \frac{2r}{n-1} \rceil, r)$-star colorable.

Proof. Let $V(C_n) = \{0, 1, \ldots, n-1\}$ and $E(C_n) = \{xy : 0 \leq x \leq n-1, y = x+1 \pmod{n}\}$.

(i) Let $n \geq 4$ be even. Two cases may occur:

Case 1. $r = 2$.

Since $n$ is even, two cases may be considered:
• \( n = 0 \mod 4 \).

Define edge colorings \( f_0 \) and \( f_1 \) of \( C_n \) as follows:
\[
f_0 : 0, 1, 2, 3, 0, 1, 2, 3, \ldots, 0, 1, 2, 3, \quad f_1 : 2, 3, 0, 1, 2, 3, 0, 1, \ldots, 2, 3, 0.
\]

• \( n = 2 \mod 4 \).

Define edge colorings \( f_0 \) and \( f_1 \) of \( C_n \) as follows:
\[
f_0 : 0, 1, 2, 3, 0, 1, 2, 3, \ldots, 0, 1, 2, 3, 2, 1, \quad f_1 : 2, 3, 0, 1, 2, 3, 0, 1, \ldots, 2, 3, 0, 1, 0, 3.
\]

It is easy to see that edge colorings \( f_0 \) and \( f_1 \) are star compatible in both cases.

**Case 2.** \( r > 2 \).

Define edge colorings \( f_i : E(C_n) \rightarrow \{0, 1, \ldots, 2r - 1\} \), \( 0 \leq i \leq r - 1 \), as follows. For every \( xy \in E(C_n) \) \( (y = x + 1 \mod n) \), let
\[
f_i(xy) = \begin{cases} 
  x + 2i \mod 2r & \text{if } 0 \leq x \leq n - 2, \\
  n + 1 + 2i \mod 2r & \text{if } x = n - 1.
\end{cases}
\]

For every \( 1 \leq i \leq r - 1 \), \( f_i \) is a star edge coloring of \( C_n \). Otherwise, suppose that there exists a bi-colored 4-path (or 4-cycle), say \( P : v_1v_2v_3v_4v_5 \). Since every three consecutive edges in \( C_n \setminus \{0n \sim 1\} \), that \( 0n \sim 1 \) denotes the edge between vertex 0 and vertex \( n - 1 \), have three different colors, it is enough to consider two cases: \( v_1 = n - 3, v_2 = n - 2, v_3 = n - 1, v_4 = 0, v_5 = 1, \) and \( v_1 = n - 2, v_2 = n - 1, v_3 = 0, v_4 = 1, v_5 = 2 \). In the first case, \( f_i(v_1v_2) = n - 3 + 2i \mod 2r \), and \( f_i(v_3v_4) = n + 1 + 2i \mod 2r \). Since \( 2r \geq 6 \), we have \( n - 3 \neq n + 1 \mod 2r \), which is a contradiction. In the second case, \( f_i(v_1v_2) = f_i(v_3v_4) \), and \( f_i(v_2v_3) = f_i(v_4v_5) \). It implies that \( n - 2 + 2i = 2i \mod 2r \), and \( n + 1 + 2i = 1 + 2i \mod 2r \), which is a contradiction. Thus, for every \( 0 \leq i \leq r - 1 \), \( f_i \) is a star edge coloring of \( C_n \).

We now show that these star edge colorings are pairwise star compatible. For every \( i \) and \( j \), \( 0 \leq i < j \leq r - 1 \), and every \( x \in V(C_n) \), we have
\[
C_{f_i}(x) \cap C_{f_j}(x) = \begin{cases} 
  \{n+1+2i, 2i\} \cap \{n+1+2j, 2j\} & \text{if } x = 0, \\
  \{x-1+2i, x+2i\} \cap \{x-1+2j, x+2j\} & \text{if } 1 \leq x \leq n - 2, \\
  \{n-2+2i, n+1+2i\} \cap \{n-2+2j, n+1+2j\} & \text{if } x = n - 1.
\end{cases}
\]

Since \( 0 \leq i < j \leq r - 1 \) and \( n \) is even, \( 2i \neq 2j \mod 2r \) and \( n + 1 \mod 2r \) is odd.

Therefore, we conclude that \( C_{f_i}(x) \cap C_{f_j}(x) = \emptyset \), as desired.

(ii) Let \( n \geq 2r + 1 \) be odd. First, we consider the case \( r = 2 \). Since \( n \) is odd, we have two possibilities: either \( n = 1 \mod 4 \), or \( n = 3 \mod 4 \). If \( n = 1 \mod 4 \), then we provide edge colorings \( f_0 \) and \( f_1 \) of \( C_n \) with the following patterns.
\[
f_0 : 0, 1, 2, 3, 0, 1, 2, 3, \ldots, 0, 1, 2, 3, 0, 1, 2, \quad f_1 : 1, 3, 0, 1, 2, 3, 0, 1, 2, \ldots, 1, 3, 0, 1, 2.
\]
If $n = 3 \pmod{4}$, then we provide edge colorings $f_0$ and $f_1$ of $C_n$ with the following patterns.

\[
\begin{aligned}
f_0 &: 0, 1, 2, 3, 0, 1, 2, 3, \ldots, 0, 1, 2, 3, 0, 4, 2, \\
f_1 &: 4, 3, 0, 1, 2, 3, 0, 1, 2, 3, \ldots, 0, 1, 2, 3, 1.
\end{aligned}
\]

It is then easy to see that in each case edge colorings $f_0$ and $f_1$ are star compatible. Now, we consider the case $r > 2$. Assume that $n - 1 = 2rp + u$, where $u \in \{0, 2, 4, \ldots, 2(r - 1)\}$ and $p \geq 1$. Let

\[
b = \frac{n - 1 - 2r}{2} = \frac{2r(p - 1) + u}{2},
\]

and for every $0 \leq i \leq r - 1$, $b - 2i - 2 = u_i \pmod{2r}$, and

\[
x_i = \begin{cases} 
2r & \text{if } u_i = 0, \\
u_i & \text{if } u_i \neq 0.
\end{cases}
\]

For every $0 \leq i \leq r - 1$, we define ordered $(b + 1)$-tuples $T_i$ (where each entry in the tuples represents a color), as follows. For $0 \leq i \leq r - 2$, let

\[
T_i = \left(2r - 2i - 2, 2r - 2i - 1, \ldots, 2r, 1, 2, \ldots, 2r, 1, 2, \ldots, 2r, 1, 2, \ldots, x_i\right).
\]

Also, we define

\[
T_{r-1} = \left(2r, 1, 2, \ldots, 2r, 1, 2, \ldots, 2r, 1, 2, \ldots, x_{r-1}\right).
\]

We denote the $\ell$-th entry of $T_i$ by $T^\ell_i$. For every $0 \leq i \leq r - 1$, we provide edge coloring $f_i$ of $C_n$ with the following pattern. Let

\[
f_0 : T^b_0, T^{b-1}_0, \ldots, T^1_0, a_0, a_1, \ldots, a_{2r-1}, T^1_{r-1}, T^2_{r-1}, \ldots, T^b_{r-1}, q_0.
\]

For $1 \leq i \leq r - 1$, let

\[
f_i : T^b_i, T^{b-1}_i, \ldots, T^1_i, a_i, a_{i+1}, \ldots, a_{i+2r-1}, T^1_{i-1}, T^2_{i-1}, \ldots, T^b_{i-1}, q_i.
\]

In this pattern, $a_i = (2r - 1)i, a_{i+1} = (2r - 1)i + 1, \ldots, a_{i+2r-1} = (2r - 1)(i + 1)$ (arithmetics are done modulo $2r + 1$) and $q_i$ is determined as follows. If $b = 0$, then $q_i = a_{i+2r} = (2r - 1)(i + 1) + 1 \pmod{2r + 1}$. If $b > 1$, then $q_i = T^{b+1}_i$. If $b = 1$, then $q_i$ is adjacent to $T^1_{i-1}$ and $T^1_i$. Since $T^1_{i-1}$ and $T^1_i$ are even, it is reasonable to choose $q_i$ from $S_i = \{1, 3, \ldots, 2r - 1\} \setminus \{a_i, a_{i+2r-1}\}$. Now, to determine the value of $q_i$, we describe a bipartite graph $G(X, Y)$, as follows. Let $X = \{S_0, S_1, \ldots, S_{r-1}\}$ and $Y = \{1, 3, \ldots, 2r - 1\}$. Note that $|X| = |Y|$. Also, vertex $S_\beta$ is adjacent to vertex $s_\beta \in Y$ if and only if $s_\beta$ belongs to $S_\alpha$. For each $1 \leq i \leq r - 1$, $a_i$ (mod $2r + 1$) and $a_{i+2r-1}$ (mod $2r + 1$) are odd. Moreover, $a_0$ (mod $2r + 1$) is even and $a_{2r-1}$ (mod $2r + 1$) is odd. By definition of $S_i$, we have the following facts.
• For every $0 \leq i \leq r - 1$, $|S_i| \geq r - 2$.
• For every $0 \leq i \leq r - 2$, $|S_i \cup S_{i+1}| \geq r - 1$.
• For every $0 \leq i \leq r - 3$, $|S_i \cup S_{i+2}| = r$.

Thus, $X$ satisfies the marriage condition and by the Hall’s marriage theorem [4], graph $G(X, Y)$ has a perfect matching. In a perfect matching of $G(X, Y)$, we take the label of the vertex that is matched to $S_i$ as $q_i$.

It is easy to see that every $f$, $0 \leq i \leq r - 1$, is a proper edge colorings of $C_n$. To prove that for every $0 \leq i \leq r - 1$, $f_i$ is a star edge coloring, it suffices to show that every 4-path $P$ in $C_n$ is not bi-colored. For every $0 \leq j \leq 2r - 3$ and $1 \leq k \leq b - 2$, we have $a_j \neq a_{j+2}$ and $T^k_i \neq T^{k+2}_i$; thus if $P$ has at least three consecutive edges with colors from $\{a_1, \ldots, a_{i+2-1}\}$ or $\{T^1_i, \ldots, T^b_i\}$, then $P$ is not bi-colored. Hence, we consider the following cases.

If $P$ is bi-colored with colors $T^2_1, T^1_i, a_i, a_{i+1}$, or $q_i, T^1_i, a_i, a_{i+1}$, then $a_{i+1} = T^1_i$. Therefore, $(2r - 1)i + 1 = 2r - 2i - 2 (\bmod 2r + 1)$. Hence, $(2r + 1)i = 2r - 3 (\bmod 2r + 1)$, which is a contradiction.

If $P$ is bi-colored with colors $a_{i+2r-2}, a_{i+2r-1}, T^1_i, T^2_{i-1}$, or $a_{i+2r-2}, a_{i+2r-1}, T^1_{i-1}, q_i$, then $a_{i+2r-2} = T^1_{i-1}$. Therefore, $(2r - 1)(i + 1) - 1 = 2r - 2(i - 1) - 2 (\bmod 2r + 1)$. Hence, $(2r + 1)(i + 1) = 2 (\bmod 2r + 1)$, which is a contradiction.

If $P$ is bi-colored with colors $a_{i+2r-1}, T^1_{i-1}, q_i, T^1_i$, or $T^1_{i-1}, q_i, T^1_i, a_i$, then $T^1_{i-1} = T^1_i$. Therefore, $2r - 2(i - 1) - 2 = 2r - 2i - 2 (\bmod 2r + 1)$, which is a contradiction.

If $P$ is bi-colored with colors $a_{i+2r-1}, q_i, a_i, a_{i+1}$, or $a_{i+2r-2}, a_{i+2r-1}, q_i, a_i$, then $a_{i+2r-1} = a_i$. Therefore, $(2r - 1)(i + 1) = (2r - 1)i (\bmod 2r + 1)$. Hence, $2r - 1 = 0 (\bmod 2r + 1)$, which is a contradiction.

If $b > 1$ and $P$ is bi-colored with colors $T^b_{i-1}, q_i, T^b_i, T^{b-1}_i$, or $T^{b-1}_{i-1}, T^b_{i-1}, q_i, T^b_i$, then $T^b_{i-1} = T^b_i$, which is a contradiction.

Thus, for every $0 \leq i \leq r - 1$, $f_i$ is a star edge coloring. Now, we show that the $f_1, \ldots, f_{r-1}$ are pairwise star compatible. Let $c = n - b$, and for every vertex $x \in V(C_n)$, let $d_x = x - b$. Thus, for all natural numbers $i$ and $j$, $0 \leq i < j \leq r - 1$, we have

$$C_{f_i}(x) \cap C_{f_j}(x) = \begin{cases} 
\{a_i, a_{i+2r}\} \cap \{a_j, a_{j+2r}\} & \text{if } x = 0, b = 0, \\
\{T^b_i, q_i\} \cap \{T^b_j, q_j\} & \text{if } x = 0, b > 0, \\
\{T^b_{i-1}, T^b_{j-1}\} \cap \{T^b_{i-1} - x, T^b_{j-1} - (x-1)\} & \text{if } 0 < x < b, \\
\{T^b_i, a_i\} \cap \{T^b_j, a_j\} & \text{if } x = b, b > 0, \\
\{a_{i+d_x-1}, a_{i+d_x}\} \cap \{a_{j+d_x-1}, a_{j+d_x}\} & \text{if } b < x < c - 1, \\
\{a_{i+2r-1}, q_i\} \cap \{a_{j+2r-1}, q_j\} & \text{if } x = c - 1, b = 0, \\
\{a_{i+2r-1}, T^1_{i-1}\} \cap \{a_{j+2r-1}, T^1_{j-1}\} & \text{if } x = c - 1, b > 0, \\
\{T^b_{i-1}, T^b_{j-1}\} \cap \{T^b_{i-1} - (c-1), T^b_{j-1} - (c-2)\} & \text{if } c \leq x < n - 1, b > 1, \\
\{T^b_{i-1}, q_i\} \cap \{T^b_{j-1}, q_j\} & \text{if } x = n - 1, b > 0. 
\end{cases}$$
For every $0 \leq s \leq r - 1$, it is obvious that $|T^*_i - T^*_j| \geq 2$ is even and $|a_i - a_j| \geq 2$. Thus, we have $C_{f_i}(x) \cap C_{f_j}(x) = \emptyset$. As an example, in Figure 2, three pairwise star compatible colorings of $C_{15}$ by seven colors are shown. Here, $T_0 = (4, 5, 6, 1, 2)$, $T_1 = (2, 3, 4, 5, 6)$, $T_2 = (6, 1, 2, 3, 4)$, $r = 3$, $b = 4$, $p = 2$, and $u = 2$.

![Figure 2: Three compatible star edge colorings of $C_{15}$.
](image)

(iii) If $n \geq 2r + 1$, then by assertion (ii) we are done. Thus, let $3 \leq n = 2p + 1 < 2r + 1$ and $a = \left\lceil \frac{2r}{n-1} \right\rceil - 1$. We show that $C_n$ is $(2r + 1 + a, r)$-star colorable. By applying assertion (ii) $a$ times, we can provide $ap$ pairwise star compatible colorings of $C_n$ with $(2p + 1)a$ colors. Note that each set of $p$ pairwise star compatible colorings uses $2p + 1$ new colors. Since

$$2r + 1 + a - a(2p + 1) = 2(r - ap) + 1 \leq n,$$

by assertion (ii), we can present $(r - ap)$ pairwise star compatible colorings with $2(r - ap) + 1$ colors. Therefore, we provide $ap + (r - ap) = r$ pairwise star compatible colorings of $C_n$ with $(2p + 1)a + 2(r - ap) + 1 = 2r + a + 1$ colors, as desired. □

By Theorems 2.1 and 2.4, we have the following corollary.

**Corollary 2.3.** For every graph $G$ and a natural number $n$, we have the following statements.

(i) If $n \geq 2$, then $\chi'_s(G \square P_n) \leq \chi'_s(G \square C_{2n}) \leq \chi'_s(G) + 2\chi(G)$.

(ii) If $n \geq 2\chi(G) + 1$ is odd, then $\chi'_s(G \square C_n) \leq \chi'_s(G) + 2\chi(G) + 1$.

(iii) If $n \geq 3$ is odd, then $\chi'_s(G \square C_n) \leq \chi'_s(G) + 2\chi(G) + \left\lceil \frac{2\chi(G)}{n-1} \right\rceil \leq \chi'_s(G) + 2\chi(G) + 3$.

### 3 Cartesian product of paths and cycles

In this section, we study the star chromatic index of grids, hypercubes, and toroidal grids. We first obtain the star chromatic index of 2-dimensional grids, and then we extend this result in order to get an upper bound on the star chromatic index of
$d$-dimensional grids and $d$-dimensional hypercubes, $d \geq 3$. Also, we obtain some upper bounds for the star chromatic index of $P_m \Box C_n$, $C_m \Box C_n$, and $d$-dimensional toroidal grids.

**Theorem 3.1.** For all natural numbers $2 \leq m \leq n$, we have

$$
\chi'_s(P_m \Box P_n) = \begin{cases} 
3 & \text{if } m = n = 2, \\
4 & \text{if } m = 2, n \geq 3, \\
5 & \text{if } m = 3, n \in \{3, 4\}, \\
6 & \text{otherwise.}
\end{cases}
$$

**Proof.** Let $V(P_m \Box P_n) = \{(i, j) : 0 \leq i \leq m - 1, 0 \leq j \leq n - 1\}$. If $m = n = 2$, then $\chi'_s(P_m \Box P_n) = \chi'_s(C_4) = 3$. By symmetry, we consider the following cases.

**Case 1.** $m = 2$ and $n \geq 3$.

It is not difficult to see that there is no 3-star edge coloring of $P_2 \Box P_3$. Hence, for every $n \geq 3$, $\chi'_s(P_2 \Box P_n) \geq \chi'_s(P_2 \Box P_3) > 3$. Now, consider the edge coloring $f_{2,n}$ of $P_2 \Box P_n$ as follows. For every $j$, $0 \leq j \leq n - 2$, let

$$
f_{2,n}((i, j)(i, j + 1)) = \begin{cases} 
 j \pmod{4} & \text{if } i = 0, \\
 j + 3 \pmod{4} & \text{if } i = 1.
\end{cases}
$$

For every $j$, $0 \leq j \leq n - 1$, let

$$
f_{2,n}((0, j)(1, j)) = j + 1 \pmod{4}.
$$

Since $f_{2,n}$ has a repeating pattern, it suffices to check that $f_{2,7}$ is a star edge coloring to see that there is no bi-colored 4-path (4-cycle) in $P_2 \Box P_7$. The edge coloring $f_{2,7}$, shown in Figure 3, is clearly a 4-star edge coloring. Therefore, for every $n \geq 3$, $\chi'_s(P_2 \Box P_n) = 4$.

![Figure 3: A 4-star edge coloring of $P_2 \Box P_7$.](image)

**Case 2.** $m = 3$ and $n \in \{3, 4\}$.

By checking all possibilities, it can be seen that there is no 4-star edge coloring of $P_3 \Box P_3$. Therefore, $\chi'_s(P_3 \Box P_4) \geq \chi'_s(P_3 \Box P_3) > 4$. In Figure 4, 5-star edge colorings of $P_3 \Box P_3$ and $P_3 \Box P_4$ are presented. Thus, $\chi'_s(P_3 \Box P_3) = \chi'_s(P_3 \Box P_4) = 5$.

**Case 3.** $m = n = 4$ or $m \geq 3$ and $n \geq 5$.

In this case, we first show that $\chi'_s(P_m \Box P_n) \geq 6$. For this purpose, we construct all possible 5-star edge colorings of $P_3 \Box P_4$ and then we show it is impossible to extend
Figure 4: A 5-star edge coloring of $P_3 \square P_3$ and a 5-star edge coloring of $P_3 \square P_4$.

these edge colorings to a 5-star edge coloring of $P_m \square P_n$, when $m = n = 4$ or $m \geq 3$, $n \geq 5$. Consider path $P : (0, 0)(1, 0)(2, 0)(2, 1)$ in $P_3 \square P_4$. In a 5-star edge coloring of this graph, edges $(0, 0)(1, 0)$ and $(2, 0)(2, 1)$ either have the same color or not. It can be checked that in each case, there is only one 5-star edge coloring of $P_3 \square P_4$. Up to symmetry and permutation, the 5-star edge coloring of $P_3 \square P_4$ is unique and is shown in Figure 4(b).

Now, we try to extend the coloring of $P_3 \square P_4$ to a 5-star edge coloring of $P_3 \square P_3$ or $P_4 \square P_4$. In Figure 5, all possibilities to obtain the desired colorings are depicted. It turns out that it is impossible and therefore $\chi'_s(P_m \square P_n) > 5$, when $m = n = 4$, or $m \geq 3$ and $n \geq 5$.

Figure 5: There is no 5-star edge coloring of $P_4 \square P_4$ and $P_3 \square P_3$.

Define the edge coloring $f_{m,n} : E(P_m \square P_n) \to \{0, 1, \ldots, 5\}$ as follows. For every $0 \leq i \leq m - 2$ and $0 \leq j \leq n - 1$,

$$f_{m,n}((i,j)(i + 1,j)) = \begin{cases} i (\text{mod } 4) & \text{if } j = 0 (\text{mod } 2), \\ i + 3 (\text{mod } 4) & \text{if } j = 1 (\text{mod } 2). \end{cases}$$

For every $0 \leq i \leq m - 1$ and $0 \leq j \leq n - 2$,

$$f_{m,n}((i,j)(i,j + 1)) = \begin{cases} 4 + (i (\text{mod } 2)) & \text{if } j = 1 (\text{mod } 4), \\ 5 - (i (\text{mod } 2)) & \text{if } j = 3 (\text{mod } 4), \\ i + 1 (\text{mod } 4) & \text{otherwise}. \end{cases}$$

Since $f_{m,n}$ has a repeating pattern, it suffices to check that $f_{7,6}$ is a 6-star edge coloring. The edge coloring $f_{7,6}$ is shown in Figure 6; we can see that there is no bi-colored 4-path (4-cycle) in $P_7 \square P_6$. □
Figure 6: A 6-star edge coloring of $P_7 \square P_6$.

By Corollary 2.2, Theorems 2.1, 2.3, and 3.1, we can obtain an upper bound on the star chromatic index of $d$-dimensional grids as follows.

**Corollary 3.1.** If $G_{\ell_1, \ell_2, \ldots, \ell_d}$ is a $d$-dimensional grid, $d \geq 2$, then

$$\chi'_s(G_{\ell_1, \ell_2, \ldots, \ell_d}) \leq 4d - 2.$$

Moreover, for $d = 2$ and $\ell_1, \ell_2 \geq 4$, this bound is tight.

**Proof.** By Theorem 3.1, if $d = 2$, then $\chi'_s(G_{\ell_1, \ell_2}) = \chi'_s(P_{\ell_1} \square P_{\ell_2}) \leq 6$, and the equality holds for $\ell_1, \ell_2 \geq 4$. By Theorem 2.3 and a similar argument as in the proof of Corollary 2.2, we conclude that $G_{\ell_1, \ell_2, \ldots, \ell_{d-2}}$ is $(4(d - 2), 2)$-star colorable. Thus, by Theorems 2.1 and 3.1, we have

$$\chi'_s(G_{\ell_1, \ell_2, \ldots, \ell_d}) \leq 4(d - 2) + \chi'_s(P_{\ell_1} \square P_{\ell_2}) \leq 4d - 2.$$

□

**Corollary 3.2.** If $Q_d$ is the $d$-dimensional hypercube with $d \geq 3$, then

$$\chi'_s(Q_d) \leq 2d - 2.$$

Moreover, this bound is tight for $d = 3$ and $d = 4$.

**Proof.** It is known that for every natural number $d \geq 2$, $Q_d = Q_{d-1} \square P_2$, $\chi(Q_d) = 2$, and $\chi'_s(Q_3) = 4$ (see proof of Theorem 5.1 in [2]). Therefore, by Corollary 2.1, we have

$$\chi'_s(Q_d) \leq \chi'_s(P_2)\chi(Q_{d-1}) + \chi'_s(Q_{d-1}) \leq 2 + \chi'_s(Q_{d-1}).$$

Thus, by induction on $d$, it follows that $\chi'_s(Q_d) \leq 2(d - 3) + \chi'_s(Q_3) = 2d - 2$.

Since $Q_4 = C_4 \square C_4$ and $\chi'_s(P_4 \square P_4) = 6$, we conclude that $\chi'_s(Q_4) \geq 6$, which implies the equality. Therefore, for $d = 3$ and $d = 4$ the upper bound is tight. □
Note that, for all natural numbers $m$ and $n$, $P_m \Box P_n$ is a subgraph of $P_m \Box C_n$ and $C_m \Box C_n$. Hence, $\chi'_s(P_m \Box P_n)$ that is determined in Theorem 3.1, is a lower bound for $\chi'_s(P_m \Box C_n)$ and $\chi'_s(C_m \Box C_n)$. In the following theorem, we give some upper bounds for the star chromatic index of the Cartesian product of paths and cycles.

**Theorem 3.2.** For every natural number $m$,

(i) if $n$ is an even natural number, then $\chi'_s(P_m \Box C_n) \leq 7$;

(ii) if $n$ is an odd natural number, then $\chi'_s(P_m \Box C_n) \leq 8$.

**Proof.**

(i) If $n \geq 4$ is even, then $C_n$ is $(4,2)$-star colorable. Therefore, by Theorem 2.1, we have

$$\chi'_s(P_m \Box C_n) \leq 4 + \chi'_s(P_m) = 7.$$ 

(ii) If $n \geq 5$ is odd, then $C_n$ is $(5,2)$-star colorable and by Theorem 2.1, $\chi'_s(P_m \Box C_n) \leq 8$. If $n = 3$, then we define edge coloring $g_{m,3}$ as follows. For every $0 \leq i \leq m - 1$ and $0 \leq j \leq 2$,

$$g_{m,3}((i,j)(i,j+1 \pmod n)) = \begin{cases} j, & \text{if } i = 0 \pmod 2, \\ j + 3, & \text{if } i = 1 \pmod 2. \end{cases}$$

For every $0 \leq i \leq m - 2$ and $0 \leq j \leq 2$,

$$g_{m,3}((i,j)(i+1,j)) = \begin{cases} j + 1, & \text{if } i = j \pmod 3, \\ 6, & \text{if } i = j + 1 \pmod 3, \\ 7, & \text{if } i = j + 2 \pmod 3. \end{cases}$$

Since $g_{m,3}$ has a repeating pattern, it suffices to check that $g_{4,3}$ is a star edge coloring. Edge coloring $g_{4,3}$ is shown in Figure 7, and it is easy to see that there is no bi-colored 4-path (4-cycle) in $P_4 \Box C_3$. Thus, we conclude that $\chi'_s(P_m \Box C_3) \leq 8$, for every $m \geq 2$. 

**Figure 7:** An 8-star edge coloring of $P_4 \Box C_3$.

By Theorems 2.1 and 2.4, we give some upper bounds on the star chromatic index of the Cartesian product of two cycles.
Theorem 3.3. For all natural numbers \( m, n \geq 3 \), we have the following statements.

(i) If \( m \) and \( n \) are even, then \( \chi'_s(C_m \Box C_n) \leq 7 \).

(ii) If \( m \neq 3 \) is odd and \( n \) is even, then \( \chi'_s(C_m \Box C_n) \leq 8 \).

(iii) If \( m = 3 \) and \( n \) even, then \( \chi'_s(C_m \Box C_n) \leq 9 \).

(iv) If \( m \) and \( n \) are odd, then \( \chi'_s(C_m \Box C_n) \leq 10 \).

Proof. (i) Let \( m \) and \( n \) be even. Thus, \( \chi'_s(C_m) = 3 \) and by Theorem 2.4(i), \( C_m \) is \((4,2)\)-star colorable. Applying Theorem 2.1, we conclude that \( \chi'_s(C_m \Box C_n) \leq 4 + \chi'_s(C_n) = 7 \).

(ii) Let \( m > 3 \) be odd and \( n \) be even. By Theorem 2.4(ii), \( C_m \) is \((5,2)\)-star colorable. Therefore, by Theorem 2.1, \( \chi'_s(C_m \Box C_n) \leq 5 + \chi'_s(C_n) = 8 \), as desired.

(iii) Let \( m = 3 \) and \( n \) be even. By Theorem 2.4(iii), \( C_3 \) is \((6,2)\)-star colorable. Then, by Theorem 2.1, \( \chi'_s(C_3 \Box C_n) \leq 6 + \chi'_s(C_n) = 9 \).

(iv) Let \( m \) and \( n \) be odd. A 6-star edge coloring of \( C_3 \Box C_3 \) and a 7-star edge coloring of \( C_5 \Box C_5 \) are shown in Figure 8.

![Figure 8: A 6-star edge coloring of \( C_3 \Box C_3 \) and a 7-star edge coloring of \( C_5 \Box C_5 \).](image)

Remark. By giving some more complex pattern for the star edge coloring of \( P_m \Box C_n \) and \( C_m \Box C_n \), we have found that \( \chi'_s(P_m \Box C_n) \leq 7 \) and \( \chi'_s(C_m \Box C_n) \leq 8 \), for all natural numbers \( m \) and \( n \) [9].

We propose the following conjecture.
Conjecture 3.1. For all natural numbers \(m, n\),

\[
\chi_s'(C_m \square C_n) \leq 7.
\]

By Corollary 2.2, Theorems 2.1, 2.4, and 3.3, we obtain the following upper bounds on the star chromatic index of \(d\)-dimensional toroidal grids.

Corollary 3.3. For all natural numbers \(d \geq 2\) and \(\ell_1, \ell_2, \ldots, \ell_d \geq 3\), we have the following statements.

(i) The toroidal grid \(T_{2\ell_1, 2\ell_2, \ldots, 2\ell_d}\) is \((4d, 2)\)-star colorable and \(\chi_s'(T_{2\ell_1, 2\ell_2, \ldots, 2\ell_d}) \leq 4d - 1\).

(ii) If every \(\ell_i > 3\), \(1 \leq i \leq d\), then the toroidal grid \(T_{\ell_1, \ell_2, \ldots, \ell_d}\) is \((7d, 3)\)-star colorable and \(\chi_s'(T_{\ell_1, \ell_2, \ldots, \ell_d}) \leq 7d - 4\).

Proof. By Theorem 2.4, every even cycle is \((4, 2)\)-star colorable and every odd cycle, except \(C_3\), is \((7, 3)\)-star colorable. Then, by Corollary 2.2, \(T_{2\ell_1, 2\ell_2, \ldots, 2\ell_d}\) is \((4d, 2)\)-star colorable and \(T_{\ell_1, \ell_2, \ldots, \ell_d}\) is \((7d, 3)\)-star colorable. Thus, by Theorems 2.1 and 3.3, we have

\[
\chi_s'(T_{2\ell_1, 2\ell_2, \ldots, 2\ell_d}) \leq 4(d - 2) + \chi_s'(C_{2\ell_{d-1}} \square C_{2\ell_d}) \leq 4d - 1,
\]

and

\[
\chi_s'(T_{\ell_1, \ell_2, \ldots, \ell_d}) \leq 7(d - 2) + \chi_s'(C_{\ell_{d-1}} \square C_{\ell_d}) \leq 7d - 4.
\]

\[\square\]

4 Conclusion

In this paper, we have found a tight upper bound for the star chromatic index of the Cartesian product of two arbitrary graphs \(G\) and \(H\). Then, we determined the exact value of \(\chi_s'(P_m \square P_n)\) for all natural numbers \(m, n \geq 2\). Moreover, we presented upper bounds for the star chromatic index of the Cartesian product of a path and a cycle and the Cartesian product of two cycles. We conjectured that, for all natural numbers \(m, n\), \(\chi_s'(C_m \square C_n) \leq 7\). Finally, we have obtained upper bounds for the star chromatic index of grids, hypercubes, and toroidal grids.
