I. INTRODUCTION

The Debye-Hückel (DH) model originated in the physics of electrolytes \textsuperscript{1}, that is, fluids of charged particles interacting through a Coulomb potential. It is the linearized version of the classical “Hartree-like” mean-field model, which is often called Non-Linear Debye-Hückel (NLDH) model or Poisson-Boltzmann model in the context of electrolytes. These two models can be extended to arbitrary interaction potentials, leading respectively to the DH and NLDH models of classical fluids, with the corresponding integral equations.

Although it is based on very strong assumptions, the DH model gives physical insight into the screening of interaction potentials and the decay of correlation functions, both in the framework of simple and multicomponent fluids. The DH model is valid in the low-coupling limit, that is, in the limit of small interactions compared to the kinetic energy of the particles. More sophisticated models of classical fluids exist, as for instance the Hyper-Netted Chain (HNC) \textsuperscript{2} or Percus-Yevick \textsuperscript{3} models, which account for part of the correlations. However, some theoretical studies also proceed by introducing corrections, using the low-coupling DH limit as a starting point (see \textsuperscript{4, 5}). It was also recently shown that in the DH model, the energy and virial routes are thermodynamically consistent for any potential \textsuperscript{6}. For these reasons, the DH model is of permanent theoretical interest.

Moreover, in a number of applications, modified versions of the DH model are used, as for example in the physics of electrolytes \textsuperscript{7, 8} or in plasma physics \textsuperscript{9, 10}. The DH model therefore also has some practical interest.

In the case of a long-range attractive potential, the linearization performed in the DH model allows one to circumvent the “classical catastrophe” of collapsing particles. To some extent, this explains why this model is so common in plasma physics as well as in the physics of electrolytes.

Apart from the historical derivation as a linearized mean-field theory of a charged-particle mixture \textsuperscript{1}, the DH model of simple fluids can be obtained from the so-called “Percus trick” \textsuperscript{11} or from a diagrammatic analysis \textsuperscript{12, 13, 14}. In this framework, it is also useful to have a variational derivation of simple fluid models, using expressions of the free-energy as a functional of the ion-ion pair correlation function. Such a variational expression can be used in a more general theory that also includes the ion electronic structure.

A free-energy functional is available in the HNC theory \textsuperscript{15, 16}. However, in the well-known DH theory, an expression of the free-energy as a functional of the pair correlation function has not been yet proposed. The purpose of this paper is to present a brief derivation of such an expression, which can be seen as the DH equivalent to the HNC free-energy functional of Morita and Hiroike \textsuperscript{15}, also derived by Lado \textsuperscript{16}.

II. DEBYE-HÜCKEL INTEGRAL EQUATION

The DH integral equation for a homogeneous simple fluid with the given pair potential \( u(r) \) writes (see for example \textsuperscript{11}, Eq. (6.5)):

\[
 h(r) = -\beta u(r) - \varrho \beta \int d^3 r' \{ h(r') u(|r - r'|) \}
\]  

(1)

where \( \varrho \) is the particle density of the fluid, \( \beta \) the inverse temperature, and \( h(r) = g(r) - 1, g(r) \) being the usual pair distribution function.

For some particular pair potentials such as the Coulomb \((1/r)\) or Yukawa \((e^{-\alpha r}/r)\) potentials, this equation can be recast as a differential equation (Poisson...
equation in the Coulomb case, Helmholtz equation in the Yukawa case). In a diagrammatic analysis, Eq. (11) corresponds to the sum of all $u$-bond chain diagrams. Eq. (11) can also be seen as an Ornstein-Zernicke relation with the simplest closure $c(r) = -\beta u(r)$, where $c(r)$ is the direct correlation function.

The Fourier transform $\mathcal{F}_k$ of a function $\mathcal{F}(r)$ is defined as:

$$\mathcal{F}_k = \int d^3r \{ \mathcal{F}(r)e^{ikr} \}$$

For a potential that has a Fourier transform, Eq. (11) can be rewritten in the Fourier space as the algebraic relation:

$$h_k = -\beta u_k - g\beta h_k u_k$$

which has the direct formal solution:

$$h_{eq,k} = -\beta u_{s,k} : u_{s,k} \equiv \frac{u_k}{1 + g\beta u_k}$$

Here, $h_{eq,k}$ denotes the DH equilibrium correlation function and $u_{s,k}$ denotes the screened potential, both in the Fourier space.

For any long-range potential (i.e. Coulombic at infinity), $\lim_{k \to 0} u_k \sim k^{-2}$, which implies $u_{k=0} = -g^{-1}$. This is the case in any model that can be written as an Ornstein-Zernicke equation with a direct correlation function that includes the interaction potential.

In the following, the pair potential $u(r)$ will be replaced by $u^\xi(r) = \xi u(r)$, $\xi$ being a charge parameter, and the corresponding $\xi$ indices will label $h_{eq}^\xi$, $u^\xi$ and $u_k^\xi$.

### III. EXPRESSION OF THE FREE-ENERGY FUNCTIONAL

We consider a system which is immersed in a rigid, homogeneous, “neutralizing” background. Such background do not impact on the equations-of-motion or on the DH integral equation. It however leads to renormalized energies by accounting for the contribution:

$$E_{eq} = \frac{\rho^2}{2} \int d^3r \{ u^\xi(r) \}$$

which cancels the divergences of energies in case of a long-range potential. In case of a short-range potential, one can disregard any background by removing this contribution. In the following, we will address the configurational part of the renormalized free-energy and give its expression as a functional of the pair correlation function.

In the particular case of the Coulomb potential: $u^\xi(r) \equiv \xi/r$, it is easy to check that if one minimizes w.r.t. $h(r)$ the following functional $A^\xi \{ \varrho, \beta, h(r) \}$:

$$\frac{A^\xi}{\beta} = \frac{2g^2}{3\beta} \int d^3r \left\{ h(r) \left( \frac{h(r)}{2} + \frac{\beta \xi}{r} \right) + \frac{\beta \xi}{2} \int d^3r' \left\{ \frac{h(r')}{|r-r'|} \right\} \right\}$$

one gets Eq. (11). This functional also yields all the well-known equilibrium results for the renormalized configurational internal energy $U^\xi_{eq}$, free-energy $A^\xi_{eq}$, and pressure $P^\xi_{eq}$ (see, for example, [27] §78), namely:

$$\frac{U^\xi_{eq}}{V} = \frac{\partial}{\partial \beta} \left( \frac{\beta A^\xi_{eq}}{V} \right) = \frac{\partial}{\partial \beta} \left( \frac{A^\xi}{V} \right) |_{eq} = -\frac{\xi \varrho}{2} \sqrt{4\pi \varrho \beta \xi}$$

$$A^\xi_{eq} = \frac{2}{3} \frac{U^\xi_{eq}}{V}$$

$$P^\xi_{eq} = g^2 \frac{\partial}{\partial \varrho} \left( \frac{A^\xi_{eq}}{\beta \varrho V} \right) = g^2 \frac{\partial}{\partial \varrho} \left( \frac{A^\xi}{\beta \varrho V} \right) |_{eq} = \frac{1}{3} \frac{U^\xi_{eq}}{V}$$

where $|_{eq}$ means that the functional is taken at the DH equilibrium, that is, for $h(r) = h_{eq}^\xi(r)$ from Eq. (11). We stress that Eqs (7), (8), (9) hold for a One-component Classical Plasma (OCP) with the contribution of the neutralizing background included.

A slightly more complicated functional can be guessed as well in the Yukawa-OCP case: $u^\xi(r) = \xi \exp(-\varrho r)/r$.

The present derivation aims at giving a general form of the free-energy functional for a simple fluid with any pair potential $u(r)$. As in [20], we use Debye’s charging method and build an expression of the renormalized configurational free-energy functional $A^\xi \{ \varrho, \beta, u(r), h(r) \}$ from the equilibrium relation:

$$\frac{A^\xi_{eq} \{ \varrho, \beta, u(r) \}}{V} = \frac{g^2}{2} \int_0^\xi \frac{d\xi'}{\xi} \int d^3r \{ h_{eq}^\xi(r) u^\xi(r) \}$$

In the case of the exact equilibrium, Eq. (11) is an exact relation. We consider the case of $|_{eq}$ denoting the DH equilibrium, with $h(r) = h_{eq}^\xi(r)$ from Eq. (11), and require Eq. (11) to hold.

Let us assume that the free-energy functional $A^\xi \{ \varrho, \beta, u(r), h(r) \}$ can be written in the form that follows:

$$\frac{A^\xi}{V} = \int \frac{d^3k}{(2\pi)^3} \left\{ f_k^\xi h_k \left( \frac{h_k}{2} + \beta \frac{u_k^\xi + g\beta h_k u_k^\xi}{2} \right) \right\}$$

where $f_k^\xi = f(\varrho, \beta, \xi, k, u_k^\xi)$ is independent of $h_k$. Minimization of $A^\xi$ w.r.t. $h(r)$ then lead to Eq. (3), i.e. to the DH equation.

Differentiating w.r.t. $\xi$, we obtain:

$$\frac{\xi}{V} \frac{\partial A^\xi_{eq}}{\partial \xi} = \frac{\xi}{V} \frac{\partial A^\xi}{\partial \xi} |_{eq}$$

$$= \int \frac{d^3k}{(2\pi)^3} \left\{ \xi \frac{\partial f_k^\xi}{\partial \xi} h_k \left( \frac{h_k}{2} + \beta \frac{u_k^\xi + g\beta h_k u_k^\xi}{2} \right) + f_k^\xi h_k \left( \frac{\beta \frac{\partial u_k^\xi}{\partial \xi} + g\beta h_k \frac{\partial u_k^\xi}{\partial \xi}}{2} \right) \right\}$$

Using $u_k^\xi = \xi u_k$, and substituting the formal equilibrium
solution of Eq. (1), we get:

\[
\frac{\xi}{V} \left( \frac{\partial A^\xi}{\partial \xi} \right) = -\frac{\beta^2}{2} \int \frac{d^3k}{(2\pi)^3} \left\{ \frac{\partial}{\partial \xi} \left( \xi f_k^\xi \right) u_{s,k}^\xi + f_k^\xi u_{s,k}^\xi \right\}
\]

(14)

On the other hand, from Eqs. (10) and (4) we can write:

\[
\frac{\xi}{V} \left( \frac{\partial A^\xi}{\partial \xi} \right) = -\frac{\beta^2}{2} \int \frac{d^3k}{(2\pi)^3} \left\{ u_{s,k}^\xi \frac{\partial f_k^\xi}{\partial \xi} \right\}
\]

(15)

Requiring Eq. (10) (or equivalently Eq. (15)) to hold, results in the equation:

\[
\frac{\partial}{\partial \xi} \left( \xi f_k^\xi \right) = \frac{\beta^2}{\xi + \beta u_k^\xi \xi^2} = \frac{\beta^2}{\beta} \frac{2}{\xi}
\]

(16)

A solution to this differential equation for \( \xi f_k^\xi \) can be looked after in the form of a series. This leads to the following expression for \( f_k^\xi \):

\[
f_k^\xi = \frac{\beta^2}{\beta} F(\beta u_k^\xi)
\]

(17)

where the function \( F \) is defined as the series:

\[
F(x) = 1 - \sum_{n=0}^{\infty} \frac{(-x)^n}{(n+1)(n+2)}
\]

(18)

The latter can be identified with the function:

\[
F(x) = \left( 1 + \frac{1}{x} \right) \left( 1 - \ln(1+x) \right)
\]

(19)

As can be seen in Eq. (17), the only dependence of \( f_k^\xi \) on \( k \) and \( \xi \) is via the potential \( u_k^\xi \).

Finally, the DH free-energy functional reads:

\[
\frac{A^\xi}{V} = \frac{\beta^2}{\beta} \int \frac{d^3k}{(2\pi)^3} \left\{ \frac{1}{\beta u_k^\xi} \left( 1 - \ln(1+\beta u_k^\xi) \right) \right\}
\]

(20)

which is the main result of the present paper.

It is worth to note the appearance of the logarithm function, both in the DH and in the HNC free-energy functionals [25, 26], which is related to the fact that the Ornstein-Zernicke relation is explicitly fulfilled in both approaches.

IV. INTERNAL ENERGY, PRESSURE AND VIRIAL THEOREM

We first consider the renormalized configurational internal energy, as defined by the thermodynamics:

\[
\frac{U^\xi_{eq}}{V} = \left. \frac{\partial}{\partial \beta} \left( \frac{\beta A^\xi_{eq}}{V} \right) \right|_{eq}
\]

(21)

As can be seen in Eq. (20), \( \beta A^\xi_{eq} / V \) is a functional of \( h(r), \varphi, \) and of the product \( \beta \xi u(r) \). As a consequence, we can write:

\[
\left. \frac{\partial}{\partial \beta} \left( \frac{\beta A^\xi}{V} \right) \right|_{eq} = \frac{\beta}{\xi} \left( \frac{A^\xi_{eq}}{V} \right)
\]

(22)

We then have, in virtue of Eq. (10):

\[
\frac{U^\xi_{eq}}{V} = \xi \left. \frac{\partial \left( \frac{A^\xi_{eq}}{V} \right)}{\partial \xi} \right|_{eq} = \int \frac{d^3r}{(2\pi)^3} \left\{ h_{eq}^r(r) u^r(r) \right\}
\]

(23)

which corresponds to the exact expression of the internal energy, with \( h_{eq}^r(r) \) taken to be the DH approximation to the equilibrium correlation function.

The result Eq. (23) can also be obtained in a more pedestrian way, by making the explicit differentiation of the free-energy expression Eq. (20) and then substituting \( h_{eq}^r(r) \). We do not reproduce this calculation here.

The virial configurational pressure as a functional of \( \varphi, u(r), h(r) \) is:

\[
P^\xi = -\frac{1}{2} \beta u_k^\xi
\]

(24)

For a potential that decays as \( 1/r \) or faster, using the Fourier representation and integrating by part, we can write from Eq. (18):

\[
P^\xi = \int \frac{d^3r}{(2\pi)^3} \left\{ h(r)r \nabla u(r) \right\}
\]

(25)

Using Eq. (4), the equilibrium virial pressure becomes:

\[
P_{v,eq} = \frac{U^\xi_{eq}}{V} - \frac{\beta^2}{2} \int \frac{dk}{(2\pi)^3} \left\{ \frac{4\pi}{3} \beta u_k^\xi \right\}
\]

(26)

Finally, we obtain:

\[
P_{v,eq} = \frac{U^\xi_{eq}}{V} + \frac{1}{2\beta} \int \frac{d^3k}{(2\pi)^3} \left( \beta u_k^\xi - \ln \left( 1 + \beta u_k^\xi \right) \right)
\]

(27)

Then, differentiating w.r.t. \( \xi \), we get:

\[
\xi \left. \frac{\partial P_{v,eq}^\xi}{\partial \xi} \right|_{eq} = -\frac{\beta^2}{2} \int \frac{d^3k}{(2\pi)^3} \left\{ u_{s,k}^\xi \right\}
\]

(28)

We now consider the equilibrium pressure, as it is defined by the thermodynamics:

\[
P_{eq}^\xi = \xi \left. \frac{\partial \left( \frac{A^\xi_{eq}}{V} \right)}{\partial \xi} \right|_{eq}
\]

(29)

Using Eq. (10), we obtain:

\[
P_{eq}^\xi = \left. \frac{\partial}{\partial \varphi} \left( \frac{A^\xi_{eq}}{V} \right) \right|_{eq}
\]

(30)
Performing the differentiation w.r.t. \( \varrho \), we end up with:

\[
P_{\text{eq}}^\xi = -\frac{\varrho^2 \beta}{2} \int_0^\xi \frac{d\xi'}{\xi} \int \frac{d^3 k}{(2\pi)^3} \left\{ \left[ u_{\varrho, k}^\xi \right]^2 \right\} \tag{31}
\]

Finally, using Eq. \((28)\), we have:

\[
P_{\text{eq}}^\xi = \int_0^\xi \frac{d\xi'}{\xi'} \left\{ \varrho' \frac{\partial P_{\text{eq}}^{\xi'}}{\partial \varrho} \right\} = P_{\varrho, \text{eq}}^\xi \tag{32}
\]

Thus, using the exact Eq. \(\text{(10)}\) in order to define the free-energy expression of Eq. \(\text{(20)}\) and the substitution of \(\tilde{f}_{\text{eq}}^k\). We do not reproduce this calculation here either.

V. CONCLUSION

Our Eq. \(\text{(20)}\) is an explicit expression of the renormalized configurational free-energy functional in the Debye-Hückel approximation. This expression allows one to obtain the Debye-Hückel equation from a minimization procedure w.r.t. the pair correlation function. In the DH case, as in the HNC case of \(\text{(25, 26)}\), requiring the exact charging relation to hold in the approximate model allows one to define a free-energy functional that yields the correct expression for the internal energy and fulfills the virial theorem. Work is now in progress in order to generalize the present formalism to multicomponent fluids, as it was done in the HNC case \(\text{(28, 29)}\).
