Background and Purpose: Analogues of fibroblast growth factor 21 (FGF21) demonstrate diverse metabolic benefits in preclinical models of type 2 diabetes, dyslipidaemia and non-alcoholic steatohepatitis (NASH), but clinical responses with different analogues are inconsistent. Efruxifermin is an Fc-FGF21 fusion protein with prolonged half-life and enhanced receptor affinity compared with native human FGF21. Efruxifermin is in clinical trials for the treatment of non-alcoholic steatohepatitis.

Experimental Approach: Efruxifermin was administered weekly to male and female Sprague Dawley rats for 4 or 26 weeks. Body and organ weights, macroscopic and microscopic pathology, clinical chemistry, blood cytology and serum and urine biomarkers were analysed to characterize the pharmacodynamics of efruxifermin and to investigate potential non-clinical toxicities following chronic administration of suprapharmacological doses of efruxifermin.

Key Results: Efruxifermin significantly reduced body weight gain after 4 and 26 weeks, despite increasing food intake. Changes in tissue pathology, clinical chemistry and serum biomarkers generally appeared to be associated with weight loss, except for a significant decrease in urine volume in both males and females without perturbed electrolyte balance. Markers of sympathetic activation, urinary corticosterone and ratio of adrenal-to-body weight were unchanged.

Conclusion and Implications: Efruxifermin attenuated body weight gain, consistent with other FGF21 analogues. In contrast to at least one other FGF21 analogue, efruxifermin decreased rather than increased urine volume. The absence of an increase in sympathetic tone in rats mirrors the unchanged salivary cortisol and systemic blood pressure following efruxifermin treatment in humans.

electrolyte balance, FGF21, fibroblast growth factor 21, hypothalamic-pituitary-adrenal axis, kidney, translational pharmacology

Abbreviations: CTX-1, type 1 collagen cross-linked C-terminal telopeptide; PEG, polyethylene glycol.
INTRODUCTION

Fibroblast growth factor 21 (FGF21) is an endocrine hormone that regulates lipid, glucose and protein homeostasis as well as energy metabolism (Tillman & Rolph, 2020). Preclinical studies have demonstrated the ability of FGF21 to reduce body weight (Kharitonenkov et al., 2005), ameliorate dyslipidaemia (Badman et al., 2007; Inagaki et al., 2007), increase insulin sensitivity (Berglund et al., 2009) and reduce hepatic steatosis (Xu et al., 2009) and fibrosis (Jimenez et al., 2018), suggesting potential as a therapy for metabolic diseases including non-alcoholic steatohepatitis (NASH).

However, therapeutic application of native FGF21 is limited by a short half-life in circulation (Kharitonenkov et al., 2007), as a result of its susceptibility to rapid cleavage and inactivation by a circulating endopeptidase, fibroblast activation protein alpha (Dunshee et al., 2016; Zhen et al., 2016). Fibroblast activation protein activity removes 10 C-terminal amino acid residues from human FGF21. This abolishes FGF21 high-affinity binding to its obligate coreceptor, β-Klotho, in turn preventing interaction of the N-terminus of FGF21 with, and signalling through, canonical FGF receptors 1c, 2c or 3c (Ogawa et al., 2007). Truncation of residues from the N-terminus of FGF21 does not impair its β-Klotho affinity but abolishes FGFR signalling. Such a truncation may functionally antagonize native FGF21 signalling (Micanovic et al., 2009; Yie et al., 2009). Using this knowledge of the structure–function relationship for FGF21, various strategies have sought to prolong FGF21 pharmacodynamic effects in vivo by reducing clearance, including Fc-fusion (Stanislaus et al., 2017), PEGylation (Mu et al., 2012), and conjugation to an antibody scaffold (Huang et al., 2013).

Non-clinical and clinical development of these different FGF21 analogues has uncovered differential pharmacology. For example, PF-05231023 (CVX-343), an antibody-conjugated FGF21 analogue, has been observed to raise heart rate and blood pressure in rats and humans but not in non-human primates (Kim et al., 2017). Interestingly, while PF-05231023 decreased body weight in rodents (Huang et al., 2013) and non-human primates (Talukdar et al., 2016), it decreased body weight in one human study (Talukdar et al., 2016) while slightly increasing body weight in another (Kim et al., 2017). PF-05231023 also increased water intake, urine output and sympathetic activity in rats, consistent with the finding of elevated blood pressure (Turner et al., 2018). Although designed as a long-acting FGF21 analogue, the C-terminus of the FGF21 moiety of PF-05231023, necessary for binding to β-Klotho, undergoes 10-fold more rapid degradation than the N-terminus, FGFR-interacting portion of the molecule (Talukdar et al., 2016; Weng et al., 2015). These different rates of degradation may underlie the divergent pharmacology seen across species and observed with weekly compared with twice-weekly dosing intervals in humans (Kim et al., 2017; Talukdar et al., 2016).

In contrast to PF-05231023, the half-lives of intact N- and C-termini of the FGF21 moiety of efruxifermin (AKR-001; AMG 876; Fc-FGF21[RGE]), a 92-kDa FGF21 analogue comprising a homodimer of two IgG1 Fc-FGF21 variant polypeptide chains, are both extended (Stanislaus et al., 2017), enabling sustained pharmacology across a once-weekly interdose interval (Kaufman et al., 2020). Weekly administration of efruxifermin reduced body weight and improved markers of glucose and lipid metabolism in patients with non-alcoholic steatohepatitis (Harrison et al., 2021). Efruxifermin also improved lipid profile and markers of glycaemic control in patients with type 2 diabetes, without increasing blood pressure (Kaufman et al., 2020). This lack of effect on blood pressure is consistent with the association of a putative loss-of-function FGF21 allele with a slight increase in systolic blood pressure in humans (Frayling et al., 2018). The pharmacodynamic effects of efruxifermin in humans recapitulate improvements in glycaemic control and in lipid and lipoprotein profiles seen in both mice and non-human primates (Stanislaus et al., 2017).

Several other FGF21 analogues are currently in clinical trials for patients with non-alcoholic steatohepatitis. Some are based on PEGylation to extend half-life, while others are antibody-based agonists of the β-Klotho/FGFR1c complex. The most extensively studied PEGylated FGF21 analogue, pegbelfermin, which lacks engineered protection of its N- or C-terminal regions, has a half-life of 19–24 h for its intact C-terminus (Charles et al., 2016). Pegbelfermin has been reported to reduce liver fat and decrease markers of liver fibrogenesis (Sanyal et al., 2019) without altering blood pressure (Charles et al., 2016, 2019; Sanyal et al., 2019). Similarly, BFKB8488A, which selectively activates the FGFR1/β-Klotho coreceptor complex, has shown robust FGF21-like pharmacodynamic effects in patients with metabolic diseases including obesity (Baruch et al., 2020), type 2 diabetes (Wong et al., 2019), and non-alcoholic fatty liver disease (Kunder et al., 2019), with no reports of increased blood pressure.

This study explores the pharmacology and toxicology of efruxifermin administered at high doses over 4 or 26 weeks to male

What is already known

- Antidyldidaemic effects of FGF21 analogues have translated from preclinical models to humans with metabolic disease.
- Urine parameter and BP changes across FGF21 analogues are inconsistent in preclinical species and humans.

What does this study add

- Unlike some FGF21 analogues, efruxifermin does not increase urine output or sympathetic tone in rats.

What is the clinical significance

- Effects of efruxifermin in rats are consistent with two clinical studies in metabolic disease patients.
and female Sprague Dawley rats. The analyses described herein focus on those pharmacological effects that have been reported to translate inconsistently from preclinical to clinical studies, which may arise from differences in stability of the N- and C-terminal regions of the respective FGF21 analogues.

2 | METHODS

2.1 | Ethics statement/ethical review

Animal studies are reported in compliance with the ARRIVE guidelines (Percie du Sert et al., 2020) and with the recommendations made by the British Journal of Pharmacology (Lilley et al., 2020). Further, animals in both studies also adhered to the USDA Animal Welfare Act (9CFR, Parts 1, 2 and 3) and the Guide for the Care and Use of Laboratory Animals (ILAR publication, 1996, National Academy Press). The study protocol was approved by the Testing Facility Institutional Animal Care and Use Committee.

2.2 | Animals

The Sprague Dawley rat was chosen as a well-characterized strain for preclinical toxicity testing. Its pharmacological responses to efruxifermin are representative of rodent species. The total number of animals, including group sizes and number of groups, was the minimum required to characterize the toxicity and toxico-kinetics of efruxifermin.

The 4-week study was conducted at Charles River Laboratories Preclinical Services (Reno, NV, USA). Eighty male and 80 female Sprague Dawley Crl:CD®IGS rats (Charles River Laboratories, Hollister, CA, USA) were 9 weeks old on Day 1 of the study. Males and females ranged in weight from 249 to 285 g and from 180 to 204 g, respectively, at Day –4 of the study. The 26-week study was conducted at Charles River Laboratories Montreal ULC (Senneville, QC, Canada). One hundred twenty male and 120 female Sprague Dawley Crl:CD(SD) rats (Charles River Canada, St. Constant, QC, Canada) were 7 weeks old on Day 1 of the study. Males and females ranged in body weight from 226 to 322 g and from 187 to 273 g, respectively, on Day 1 of the study.

2.3 | Housing and husbandry

Animals were housed individually in stainless steel cages (4-week study) or by group (up to three animals of the same sex and dosing group together) in polycarbonate cages (26-week study). They were provided with suitable environmental enrichment, except during study procedures. Study animals were acclimated to their environment for 7–14 days prior to the first day of dosing (Day 1). Room temperature was within the range of 18°C to 29°C, with relative humidity of 30% to 70%. Animals were maintained on a 12-h light/12-h dark photoperiod, except when interrupted by study procedures. PMI Nutritional International Certified Rodent Chow® No. 5002 and Lab Diet Certified CR Rodent Diet 5CR4 were provided ad libitum, except during designated procedures.

2.4 | Experimental procedures

For the 4-week and the 26-week studies, animals were assigned to groups by a computer randomization scheme, with males and females randomized separately.

All animals were observed for signs of morbidity and/or mortality twice daily without removal from cage. For detailed clinical observation, animals were removed from their cage once daily during the study. Food consumption was quantified for all animals. Body weight was measured before dosing on Day 1 then weekly thereafter on the day before dosing.

Urine was collected on ice in a cage pan overnight (at least 8 h) in metabolic caging. Food was withdrawn for urine collection, but water was provided ad libitum. For clinical pathology, blood was collected by jugular venepuncture from animals fasted overnight (for at least 8 h). Blood collection was rotated across dose groups to minimize confounding effects of collection time differences. Urine specific gravity was measured with a Clinitek 500 refractometer. Urinary corticosterone was measured using a commercial radioimmunoassay kit (MP Biomedicals Cat # 07120102). The following serum chemistry analytes were measured on either an Olympus AU640e or a Cobas 6000 analyser: sodium, potassium and chloride (ion selective electrode-based indirect measurement); urea nitrogen (urease kinetic UV); and creatinine (Jaffe kinetic colorimetric). Haematocrit was measured on an Advia 120 analyser.

Efruxifermin serum concentration was measured by a validated ELISA method using capture and detection antibodies developed by Amgen, Inc. (Thousand Oaks, CA, USA) (Kaufman et al., 2020). Toxicokinetic analysis of efruxifermin serum concentration–time data was conducted using either WinNonlin® Enterprise (Pharsight Corp., Mountain View, CA, USA) or Phoenix pharmacokinetic software version 1.4 (Certara, USA) to estimate noncompartmental parameters.

2.5 | Data and statistical analysis

The data and statistical analysis comply with the recommendations on experimental design and analysis in pharmacology (Curtis et al., 2018). Data from the 4- and 26-week studies were analysed independently. Male and female animals were analysed independently unless noted. Declared group size (n) refers to the number of independent values rather than technical replicates, and statistical analyses were undertaken only where group size was at least n = 5. Outliers were included in data analysis and presentation. Statistical tests were conducted at the 5% significance level, and comparisons are reported with P values corrected for multiple hypothesis testing.
In both studies, groups were compared using ANOVA or Kruskal-Wallis test as described below. Post hoc tests were conducted only if $F$ in ANOVA achieved $P < 0.05$. $P < 0.05$ was considered the threshold for statistical significance. Where parametric tests were used, residuals were examined to confirm underlying assumptions. All reported means are arithmetic. Statistical analyses were conducted using either SAS software version 9.2 (Cary, NC, USA) or GraphPad Prism software version 9.2.0 (GraphPad Software, San Diego, CA, USA). Data analysis was performed blinded to study groups.

In the 4-week study, differences in body weight for each dose group compared with control were assessed by two-way repeated measures ANOVA with dose and study week as factors, followed by Dunnett’s test (Figure 1). Urine volume and urine specific gravity were assessed by two-way ANOVA with dose and sex as factors, followed by Dunnett’s test (Figure 2). Serum chemistry and haematology were assessed by one-way ANOVA followed by Dunnett’s test (Table 2). In the 26-week study, to account for missing values, differences in body weight and food intake for each dose group compared

**FIGURE 1** Efruxifermin attenuates body weight gain but increases food intake in rats. Efruxifermin was administered once weekly for (a,b) 4 or (c–f) 26 weeks to (a,c,e) male or (b,d,f) female rats fed a standard chow diet. (a–d) Points and error bars represent mean and 95% confidence interval. Food intake is presented as mean ± SD. Statistical significance was tested by (a,b) two-way (dose, week) ANOVA or (c–f) mixed effects model for repeated measures followed by Dunnett’s multiple comparisons test. *$P < 0.05$ versus 0 mg kg$^{-1}$, horizontal brackets in (c) and (d) indicate range of weeks referred to by set of significance annotations. No annotation denotes lack of statistical significance.
with control were assessed by a mixed effects model for repeated measures using restricted maximum likelihood, with dose and week as factors, followed by Dunnett's test (Figure 1). Urine volume, specific gravity and corticosterone concentration were assessed by mixed effects model for repeated measures with dose and week as factors, followed by Dunnett’s test (Figure 2). Urine electrolytes, fractional excretion and creatinine differences were assessed by one-way ANOVA followed by Dunnett’s test or, for non-parametric analysis, by Kruskal-Wallis followed by Dunn’s post-test (Table 3). Adrenal weights and adrenal-to-body weight ratios were assessed by one-way ANOVA followed by Dunnett’s or Dunn’s post-test (Table 4).
2.6 Materials

Efruxifermin was synthesized as previously described (Stanislaus et al., 2017). Vehicle control was 10-mM Tris base (Sigma-Aldrich, Inc), pH 7.8, with 2.32% L-lysine (Sigma-Aldrich, Inc) and 0.008% polysorbate 20 (A&C American Chemicals LTD). To ensure stability, formulated efruxifermin and vehicle control were prepared from frozen stock solutions weekly and thawed at 2°C to 8°C prior to subcutaneous injection. Efruxifermin and control solutions were administered after equilibration to ambient temperature and were used for dosing within 3 h after removal from refrigeration. Accurate concentration of efruxifermin was confirmed multiple times during the studies for each dosing solution.

2.7 Nomenclature of targets and ligands

Key protein targets and ligands in this article are hyperlinked to corresponding entries in the IUPHAR/BPS Guide to PHARMACOLOGY http://www.guidetopharmacology.org and are permanently archived in the Concise Guide to PHARMACOLOGY 2021/22 (Alexander et al., 2021).

3 RESULTS

Once-weekly administration of efruxifermin for 4 or 26 weeks resulted in dose-related increases in exposure, with minimal accumulation (Table 1). In the 4 week study, efruxifermin reduced body weight gain over the course of the study in a dose-dependent manner, with statistically significant differences from controls in male rats at Weeks 2, 3 and 4 in the 10 and 100-mg·kg⁻¹ dose groups (Figure 1a) and in female rats at Weeks 2, 3 and 4 in the 100 mg·kg⁻¹ dose group only (Figure 1b). In the 26-week study, the magnitude of reduction in body weight gain generally increased, relative to control, over approximately the first 12 weeks of dosing, after which the groups gained weight at similar rates (Figure 1c,d), although food intake was either significantly increased (females) or trended higher (males) relative to control (Figure 1e,f).

### Table 1
Mean serum toxicokinetic parameters for male (M) and female (F) rats following once-weekly subcutaneous injection of efruxifermin for 4 or 26 weeks

| 100           | 15 | 142.1 (1.6) | 5.32 (0.40)  | 103.9 (1.4)  | 0.373 (0.059)       | 14.7 (2.1)  | 49.5 (3.2)    |

Note: Male (M) and female (F) rats were administered efruxifermin once weekly for 4 weeks. Values represent mean (SD). Statistical significance was assessed within each sex for each treatment group relative to control (0 mg·kg⁻¹), by one-way ANOVA followed by Dunnett’s or Dunn’s post-test.

Abbreviations: BUN, blood urea nitrogen; EFX, efruxifermin; mg·kg⁻¹, mg efruxifermin per kg body weight.

* n = 14.
* P < 0.05.
Once-weekly administration of efruxifermin to male and female rats for 4 weeks was associated with an approximately 50% decrease in 24-h urine volume at all doses tested (Figure 2a). Consistent with lower urine volumes, urine specific gravity was significantly higher (Figure 2b). Despite these changes, serum electrolyte concentrations, markers of renal function (creatinine and blood urea nitrogen) and blood volume (based on haematocrit) were maintained (Table 2). Urinary electrolytes were not measured in this 4-week study.

In the 26-week study, there was a trend towards decreased 24-h urine volume in both males (Figure 2c) and females (Figure 2d). At Week 13, but not at Week 26, 10 and 30 mg kg⁻¹ doses were associated with a statistically significant decrease in urine output, while mean urine output was numerically decreased in all efruxifermin dose groups at both Weeks 13 and 26 (Figure 2c). At Week 26, females administered 10 mg kg⁻¹ had significantly lower urine output than controls, consistent with the

Note: Male (M) and female (F) rats were administered the indicated dose of efruxifermin once weekly for 26 weeks before terminal necropsy. Values are mean (SD). Statistical significance was assessed for each sex independently relative to control (0 mg kg⁻¹) by one-way ANOVA followed by Dunnett’s (adrenal weight) or Dunn’s (adrenal-to-body weight ratio) post-test.

Abbreviations: EFX, efruxifermin; mg kg⁻¹, mg efruxifermin per kg body weight.
trend towards decreased urine output observed at Week 13 (Figure 2d).

Consistent with the pattern in the 4 week study, after dosing for 13 and 26 weeks, efruxifermin-treated male and female rats generally exhibited increased urine specific gravity compared with control (Figure 2e,f); however, in male rats administered 100 mg·kg\(^{-1}\), the increase was not significant at Week 13 and was absent at Week 26 (Figure 2e). Similarly, in female rats receiving more than 10 mg·kg\(^{-1}\), urine specific gravity was numerically but not statistically significantly higher at Weeks 13 and 26 (Figure 2f). Consistent with the increase in urine specific gravity following efruxifermin administration, urinary electrolyte concentrations were generally numerically higher than controls at Week 26 (Table 3). Renal function as indicated by fractional excretion rates of sodium, potassium and chloride was generally maintained, compared with control, with the exception of higher rates of chloride excretion at 100 mg·kg\(^{-1}\) in females after 13 weeks, which was not apparent after 26 weeks (Table 3). In addition, the kidneys appeared microscopically normal in all dose groups after 4 or 26 weeks of efruxifermin treatment.

To explore whether change in urine volume may have been centrally mediated by sympathetic nervous system activation (Guyton, 1990), urinary corticosterone, a marker of hypothalamic–pituitary–adrenal axis activation (Brennan et al., 2000; Buhl et al., 2007), was measured in the 26-week study. In male and female rats, doses of up to 100-mg·kg\(^{-1}\) efruxifermin did not significantly alter urinary corticosterone at either Week 13 or 26 (Figure 2g,h). Consistent with an apparent lack of long-term activation of the sympathetic nervous system, adrenal-to-body weight ratio was unchanged in all dose groups after 26 weeks (Table 4). Also consistent with a lack of stress-induced sustained corticosterone elevation (Hardy et al., 2018), no significant effect on bone remodelling was observed by histology or circulating CTX-1 (a marker of bone resorption).

4 | DISCUSSION

Efruxifermin, a 92-kDa FGF21 analogue comprising a homodimer of two IgG1 Fc-FGF21 variant fusion polypeptide chains, demonstrated a dose-dependent decrease in body weight gain relative to control-treated rats, consistent with the effects of other FGF21 analogues in rodents (Huang et al., 2013; Kharitonenkov et al., 2013; Wu et al., 2011). In the two studies reported herein, urine volume was reduced and urine concentration was generally increased by efruxifermin relative to control, although blood volume, electrolyte balance and kidney function appeared unaltered. While body weight gain was significantly reduced in efruxifermin-treated rats, food intake was increased or unchanged, consistent with an increase in energy expenditure mediated by FGF21 in rats and with browning of white adipose tissue (Gehring et al., 2020; Sarruf et al., 2010; Yilmaz et al., 2018). In clinical trials with efruxifermin dosed weekly up to 70 mg, for up to 16 weeks, urine electrolyte concentration, blood pressure and salivary cortisol level were also unchanged (Harrison et al., 2021; Kaufman et al., 2020).
N-terminal residues can result in species that may act as functional antagonists of FGF21 signalling in vivo (Micanic et al., 2009; Yie et al., 2009). In contrast, the N-terminus of the FGF21 moiety of efruxifermin is protected against cleavage by being fused to IgG1 Fc, while substitution of Pro for a Gly at position 171 (relative to mature human FGF21) greatly reduces fibroblast activation protein-mediated cleavage and inactivation of the C-terminus (Stanislaus et al., 2017). These structural modifications underlie efruxifermin’s sustained agonism of FGF21’s cognate FGFRs (Kauffman et al., 2020).

While changes in urine volume, urine concentration and blood pressure have not been reported for all FGF21 analogues developed to date, the pharmacological profile of efruxifermin appears consistent with other members of the class, with the exception of PF-05231023.

ACKNOWLEDGEMENTS
The authors thank Reshma Shringarpure and Kerry af Forselles for critical review of the manuscript. This work was supported by Akero Therapeutics.

CONFLICT OF INTEREST
EJT is an employee and shareholder of Akero Therapeutics. WJB is a consultant to Akero Therapeutics. TR is a co-founder, employee and shareholder of Akero Therapeutics.

AUTHOR CONTRIBUTIONS
WJB and TR were responsible for the conception and design of study. EJT, WJB and TR were responsible for the data analysis and interpretation. EJT and TR wrote the first draft of the manuscript. EJT, WJB and TR contributed to the final draft of the manuscript.

DECLARATION OF TRANSPARENCY AND SCIENTIFIC RIGOUR
This Declaration acknowledges that this paper adheres to the principles for transparent reporting and scientific rigour of preclinical research as stated in the BJP guidelines for Design & Analysis and Animal Experimentation, and as recommended by funding agencies, publishers and other organisations engaged with supporting research.
