ABSTRACT

Lip lesions are the most common oral mucosal lesions. Mucocele is the second most common benign soft tissue masses of the lips only next to infectious etiology. Tumors of the minor salivary glands of the lip were a rare diagnosis made clinically. Excision and histopathological examination must be done for all the lip lumps as this remains the gold standard for the diagnosis. In this article, we discuss three lip lumps which were clinically suspected as mucocele turned out to be an unexpected diagnosis which only became clear following excision and histological examination.

1. Introduction

Lip lumps can present to both the general practitioner and to ENT department. Oral mucoceles is the most common benign soft tissue masses of minor salivary glands.¹ Tumors of the minor salivary glands occur most commonly on palate, buccal mucosa, and tongue. Occurrence on the lips appears to account for approximately 5% for these tumors, with most occurring on the upper lip.² We here report three lip lump cases which were clinically suspected to be a mucocele turned out to be an unexpected diagnosis which only became clear following excision and histological examination.

2. Patient 1

A 23 year old female came with complaints of swelling in his upper lip for 2 years. There was no history of pain, trauma, fever and no history of discharge from the swelling. Excision biopsy was done and specimen was sent for histopathological examination.

Histopathological examination showed mucinous salivary glands admixed with well circumscribed benign neoplasm epithelial elements arranged in sheets, cords and ducts with scant eosinophilic cytoplasm surrounded by a chondromyxoid stroma. (Figure 1)

Fig. 1: a: Pleomorphic adenoma - benign epithelial elements in a chondromyxoid stroma (x100 H&E) b: Higher magnification shows epithelial elements (x200, H&E)

3. Patient 2

A 57 year old female presented with a swelling in the left side upper lip for past 3 months which was 3x 3 cm

gradually increasing in size. Biopsy was done and sent for histopathology.

Histopathological examination revealed a neoplasm composed of infiltrating sheets, cords, focal cribriform patterns of cells with scant cytoplasm and hyperchromatic angulated nuclei. The margins of the lesion are infiltrated by the tumor (Figure 2).

Fig. 2: a: Adenoid cystic carcinoma - malignant epithelial cells in infiltrating cords and cribriform pattern (x100 H&E); b: Higher magnification of adenoid cystic carcinoma. Inset - perineural invasion (x200, H&E)

4. Patient 3

A 23 year old male came with complaints of swelling in his lower lip for 3 years which was increased in size since 2 months. No H/O pain, fever / discharge. Excision biopsy was done and sent for histopathology.

Histopathology showed stratified squamous non-keratinized epithelium with underlying subepithelium showed bundles of hypertrophic nerve fibres which suggested a neuroma (Figure 3).

Fig. 3: a: Traumatic neuroma - hypertrophied neural bundles (x100 H&E); b: Higher magnification of hypertrophied nerve fibres (x200, H&E)

5. Discussion

Salivary gland tumors are rare, constituting 2– 6.5% of all head and neck tumors. Tumors of the minor salivary gland account for 22% of all salivary gland neoplasms. According to Patil., etal Mucocele which is the second most common lesion in lip next to infectious etiology is seen in 29.8%. Pleomorphic adenoma or mixed tumor is a benign tumor of major salivary gland. It usually present as painless, slow-growing swelling of long duration. The palate is considered as the most common intraoral site (42.8–68.8%), followed by the upper lip (10.1%) and cheek (5.5%). Other rare sites include the throat (2.5%), retromolar region (0.7%), floor of the mouth and the alveolar mucosa. Histopathologically, pleomorphic adenoma is composed of epithelial and myoepithelial elements arranged in a variety of patterns embedded in the mucopolysaccharide stroma. The tumor has a false capsule which is formed as a result of fibrosis of surrounding salivary parenchyma due to compression of the tumor.

ACC is a malignant salivary gland neoplasm which was first described by Robin and Laboulbene in 1853. Adenoid cystic carcinoma (ACC) is a rare malignant slow growing neoplasm of the salivary glands with poor prognosis. It is the most common malignant neoplasm that occurs in minor salivary gland. Intraorally, the palate is the most common site, comprising ~50% of all malignant palatal tumours. Less common sites of involvement include the lower lip, retromolar-tonsillar pillar region, sublingual gland, buccal mucosa, and floor of the mouth. In a study Waldron et al reported 426 cases of intraoral minor salivary gland neoplasms, and identified two cases of ACC on the upper lip. Histologically, this neoplasm is composed of duct-lining epithelial cells and myoepithelial cells, arranged in cribriform, tubular or in solid patterns. Contiguous perineural invasion is a hallmark of ACC.

Traumatic neuroma is a non-neoplastic proliferation of a nerve occurring in response to an injury or surgery. As oral mucosa has rich nerve supply, lies close to the connective tissue and minor salivary glands, any surgical trauma to hard or soft tissue leads to cutting of nerve fascicles. If the nerve ends not reestablished, Schwann cells proliferate and formation of neural elements resulting in neuroma. Clinically, it presents as a firm nodule that is occasionally tender or painful on palpation, Microscopically, the cells are arranged in short fascicles, whorls, or even in a storiform pattern.

6. Conclusion

Pleomorphic adenoma and adenocystic carcinoma of lips were unusual neoplasm presenting in the lip as a lump mimicking a mucocele. As these were rare in this location, without proper clinical examination and histopathological examination, the neoplasm may go unnoticed as practitioners should note that these tumors may recur after the surgical excision. Adjuvant radiotherapy should be given post surgery in cases showing microscopic evidence of tumor in excision margins or if perineural invasion is noticed to achieve better control of disease. Proper clinical history regarding surgery or trauma to be asked.
