Abstract

It is shown that Bogoliubov quasi-averages select the pure or ergodic states in the ergodic decomposition of the thermal (Gibbs) state. Our examples include quantum spin systems and many-body boson systems. As a consequence, we elucidate the problem of equivalence between Bose-Einstein condensation and the quasi-average spontaneous symmetry breaking (SSB) discussed in [SY07], [SY05] for continuous boson systems. The multi-mode extended van den Berg-Lewis-Pulé condensation of type III [vdBLP], [BZ] demonstrates that the only physically reliable quantities are those that defined by Bogoliubov quasi-averages.
1 Introduction and summary

The concept of Spontaneous Symmetry Breaking (SSB) is a central one in quantum physics, both in statistical mechanics and quantum field theory and particle physics. In this paper we restrict ourselves to continuous SSB since the breaking of discrete symmetries has been extensively studied and it has quite different properties, in particular regarding the Goldstone-Mermin-Wagner theorem for both zero $T = 0$ and non-zero $T > 0$ temperatures, see e.g. [Sim93] and references given there.

The definition of SSB is also well-known since the middle sixties and is well expounded in Ruelle’s book [Rue69], Ch.6.5.2., and references given there, as well as [BR87], Ch.4.3.4, and, from the point of view of local quantum theory in [Haa96], Ch.III.3.2. Roughly speaking, one starts from a state (ground or thermal), assumed to be invariant under a symmetry group $G$, but which has a nontrivial decomposition into extremal states, which may be physically interpreted as pure thermodynamic phases. The latter, however, do not exhibit invariance under $G$, but only under a proper subgroup $H$ of $G$.

There are basically two ways of constructing extremal states: (1) by a choice of boundary conditions (b.c) for Hamiltonians $H_\Lambda$ in finite regions; (2) by replacing $H_\Lambda \to H_\Lambda + \lambda B_\Lambda$, where $B_\Lambda$ is a suitable extensive operator and $\lambda$ a real parameter, taking first $\Lambda \supseteq \mathbb{Z}^d$ or $\Lambda \supseteq \mathbb{R}^d$, and then $\lambda \to +0$ (or $\lambda \to -0$). Here one assumes that the states considered are locally normal or locally finite, see e.g. [Sew86] and references there. Method (2) is known as Bogoliubov’s quasi-averages method [Bog07]-[Bog70].

Note that the method (1) is not of general applicability to, e.g., continuous many-body systems or quantum field theory. It is thus of particular interest to show that the Bogoliubov quasi-average ”trick” may be shown to constitute a method, whose applicability is universal, explaining, at the same time, its physical meaning. This is one of the main purpose of our paper.

An important element of discussion is a general connection between SSB and Off-Diagonal Long-Range Order (ODLRO), that was studying in papers by Fannes, Pulé and Verbeure [PV82] (see also [VZ05]), by Lieb, Seiringer and Yngvason ([SY07], [SY05]), and by Sütö [S05]. The central role played by ODLRO in the theory of phase transitions in quantum spin systems was scrutinised by Dyson, Lieb and Simon [DLS], see also the
2 Setup: continuous SSB, ODLRO and examples

To warm up we start by some indispensable basic notations and definitions, see e.g., [BR87], [BR97], [Sew86] and [Wre87]. 

Let $\mathcal{A}$ be a unital (i.e. $1 \in \mathcal{A}$) quasi-local $C^*$-algebra of observables. Recall that positive linear functionals $\omega$ over $\mathcal{A}$ are called states if they are normalised: $\|\omega\| = 1$. Note that these functionals are automatically continuous and bounded: $\|\omega\| = \omega(1)$. The state $\omega$ is called faithful if $\omega(A^*A) = 0$ implies $A = 0$.

To construct states and dynamics of quantum (boson) systems the $C^*$-setting is too restrictive and one has to use the $W^*$-setting ([BR87], [BR97]). One defines an abstract $W^*$-algebra $\mathfrak{M}$ as a unital $C^*$-algebra that possesses (as a Banach space) a predual $\mathfrak{M}_*$, i.e., $\mathfrak{M} = (\mathfrak{M}_*)^*$. Every abstract $W^*$-algebra is $\ast$-isomorphic to a concrete $W^*$-algebra $\mathcal{B}(\mathcal{H})$ of bounded operators on a Hilbert space $\mathcal{H}$. Now we can introduce normal states on $W^*$-algebra as those that any $\omega$ on the corresponding concrete $W^*$-algebra is defined by a positive trace-class operator $\rho \in C_1(\mathcal{H})$ with trace-norm $\|\rho\|_1 = 1$ such that 

$$\omega(A) = \text{Tr}_\mathcal{H}(\rho A), \text{ for all } A \in \mathcal{B}(\mathcal{H}).$$

For a finite system in the Hilbert space $\mathcal{H}_\Lambda$, the Gibbs (thermal) state is normal 

$$\omega_{\beta,\mu,\Lambda}(A) = \text{Tr}_{\mathcal{H}_\Lambda}(\rho_{\Lambda} A), \text{ for all } A \in \mathcal{B}(\mathcal{H}_\Lambda).$$

and defined by the trace-class density matrix 

$$\rho_{\Lambda} = \frac{\exp(-\beta(\mathcal{H}_\Lambda - \mu N_\Lambda))}{\Xi_{\Lambda}(\mu, \beta)}.$$ 

(2.2)

Here $\Lambda$ is a finite domain in $\mathbb{Z}^d$ for quantum spin systems, or in $\mathbb{R}^d$ for continuous many-body systems and $\Xi_{\Lambda}$ is the grand-canonical partition function 

$$\Xi_{\Lambda}(\mu, \beta) := \text{Tr}_{\mathcal{H}_\Lambda} \exp(-\beta(\mathcal{H}_\Lambda - \mu N_\Lambda)),$$ 

(2.3)

with $\beta = 1/k_B T$ the inverse temperature, $\mu$ the chemical potential for continuous quantum system. For a boson continuous quantum system the Hilbert space $\mathcal{H}_\Lambda$ coincides with the symmetric Fock space $\mathfrak{F}_{\text{symm}}(L^2(\Lambda)), \text{ and } \mathfrak{C}_\Lambda^2 = \bigotimes_{i=1}^N \mathfrak{C}_i^2$ for quantum spin systems, with $N = V = |\Lambda|$, the number of points in $\Lambda$. The thermodynamic limit in both cases will be denoted by $V \to \infty$. Operator $A$ in (2.1) is an element of a local algebra $\mathfrak{M}_\Lambda = \mathcal{B}(\mathcal{H}_\Lambda)$.
of bounded operators on $\mathcal{H}_A$. By $H_A$ we denote the Hamiltonian of the system in a finite domain $\Lambda$, and by $N_A$ the corresponding number operator. If $\Omega_{\Lambda} \in \mathcal{H}_A$ is the ground-state vector of operator $H_A - \mu N_A$, then the ground state ($T = 0$) is defined by

$$\omega_{\infty,\mu,A}(A) := (\Omega_{\Lambda}, A\Omega_{\Lambda}) \text{ for } A \in \mathcal{A}_A . \quad (2.4)$$

By $\omega_{\beta,\mu}$ and $\omega_{\infty,\mu}$ we denote thermal and ground states for the infinite-volume (thermodynamic) limit of the finite-volume states (2.1) and (2.3), in the sense that

$$\omega_{\beta,\mu}(A) = \lim_{V \to \infty} \omega_{\beta,\mu,A}(A) \text{ and } \omega_{\infty,\mu}(A) = \lim_{V \to \infty} \omega_{\infty,\mu,A}(A) , \quad A \in \bigcup_{\Lambda \subset \mathbb{R}^d \text{ or } \mathbb{Z}^d} \mathcal{A}_A . \quad (2.5)$$

Now we recall that a $C^*$-dynamics on a $C^*$-algebra $\mathcal{A}$ is a strongly continuous one-parameter group of $^*$-automorphisms: $\mathbb{R} \ni t \mapsto \tau_t$ of $C^*$. Then a $C^*$-dynamical system is a corresponding pair $(\mathcal{A}, \tau_t)$. Note that the strong continuity of $\{\tau_t\}_{t \in \mathbb{R}}$ on $\mathcal{A}$ means that the map $t \mapsto \tau_t(A)$ is norm-continuous for any $A \in \mathcal{A}$. Therefore, $C^*$-dynamical systems are completely characterised by the corresponding densely defined and closed in $\mathcal{A}$ infinitesimal generators.

It is also well-known that the $C^*$-dynamical systems are too restrictive for boson systems, that forces to use the $W^*$-setting. Let $\mathcal{M}$ be a von Neumann algebra ($W^*$-algebra) and let $\mathbb{R} \ni t \mapsto \tau_t$ be a one-parameter group of weak*-continuous $^*$-automorphisms ($W^*$-dynamics) of $\mathcal{M}$. Then the pair $(\mathcal{M}, \tau_t)$ is called a $W^*$-dynamical system. The continuity condition on the group $\{\tau_t\}_{t \in \mathbb{R}}$ means that the weak*-densely defined and closed in $\mathcal{M}$ infinitesimal generator corresponding to the $W^*$-dynamics can be defined in the weak*-topology similar to the $C^*$-setting.

We comment that it is this $W^*$-setting, which is appropriate for representations of the Canonical Commutation Relations (CCR) and description of boson systems by the Weyl algebra [BR97], [PiMe]. We shall also use it for quantum spin systems, and, therefore, throughout the whole paper.

**Definition 2.1.** Consider a $W^*$-dynamical system $(\mathcal{M}, \tau_t)$. A state on $\mathcal{M}$ is called $\tau$-invariant if $\omega \circ \tau_t = \omega$ for all $t \in \mathbb{R}$. If in addition this state is normal, we refer to the triplet $(\mathcal{M}, \tau_t, \omega)$ as to a Quantum Dynamical System (QDS) generated by $(\mathcal{M}, \tau_t)$.

Recall that GNS representation $\pi_\omega$ of the QDS, which is induced by the invariant state $\omega$, is denoted by the triplet $(\mathcal{H}_\omega, \pi_\omega, \Omega_\omega)$. Here, $\Omega_\omega$ is a cyclic vector for $\pi_\omega(\mathcal{M})$ in the Hilbert space $\mathcal{H}_\omega$. The unicity of the GNS representation implies that there exists a unique one-parameter group $t \mapsto U_\omega(t)$ of unitary operators on $\mathcal{H}_\omega$ such that

$$\pi_\omega(\tau_t(A)) = U_\omega(t)\pi_\omega(A)U_\omega^*(t) , \quad U_\omega(t)\Omega_\omega = \Omega_\omega , \quad (2.6)$$

for any $t \in \mathbb{R}$ and $A \in \mathcal{M}$.

Since we assumed $\omega$ to be normal, the group $\{U_\omega(t)\}_{t \in \mathbb{R}}$ is strongly continuous and there exists (by the Stone theorem) a unique self-adjoint generator $H_\omega$ of this unitary group such that

$$\pi_\omega(\tau_t(A)) = e^{itH_\omega}\pi_\omega(A)e^{-itH_\omega} , \quad H_\omega\Omega_\omega = 0 . \quad (2.7)$$
We note that GNS construction applied directly to a $C^*$-dynamical system with invariant state $\omega$ defines a normal extension of this state to an enveloping von Neumann algebra. Therefore, it maps the $C^*$-dynamical system into a $W^*$-dynamical system with a normal invariant state. Hence, instead of QDS one can start with GNS representation of the $C^*$-algebra $A$.

In the context of infinite boson system we suppose also that the time-invariant $\omega$ is such that restriction to $A_\Lambda$ (or $M_\Lambda$) is given by $\omega_{\beta,\mu,\Lambda}$ (2.1), (2.2), (2.3)

Now let $G$ be a group and $\{\tau_g\}_{g \in G}$ be the associated group of $*$-automorphisms in $A$.

Suppose that $\tau_g$ leaves $\omega$ invariant: $\omega(\tau_g(A)) = \omega(A), \forall A \in A, \forall g \in G$. (2.8)

Then one can find on the GNS Hilbert space $H_\omega$ a unique group of unitary operators $\{U_g\}_{g \in G}$ such that $\pi_\omega(\tau_g(A)) = U_g \pi_\omega U_g^* \pi_\omega \Omega_\omega = \Omega_\omega$. (2.9)

It is easy to show (see, e.g., [Wre87]) that the natural candidate for $U_g$, given by $U_g \pi_\omega(A) \Omega_\omega = \pi_\omega(\tau_g(A)) \Omega_\omega$, (2.10)

indeed fulfills these requirements. The $G$-invariant states forms a convex and compact in the weak*-topology set, that we denote by $E^G_A$.

The same properties are evidently shared by the set $E_A$ of all states on $A$. An extremal invariant or ergodic state is a state $\omega \in E^G_A$, which cannot be written as a proper convex combination of two distinct states $\omega_1, \omega_2 \in E^G_A$:

$$\omega \neq \lambda \omega_1 + (1 - \lambda) \omega_2 \text{ with } 0 < \lambda < 1 \text{ unless } \omega_1 = \omega_2 = \omega.$$ (2.11)

There exists an alternative characterization: we say that a state $\omega_1$ majorizes another state $\omega_2$ if $\omega_1 - \omega_2$ is a positive linear functional on $A$, i.e., $(\omega_1 - \omega_2)(A^*A) \geq 0 \forall A \in A$. Clearly, if a state is a convex combination of two others, it majorizes both, and a state $\omega$ is said to be pure if the only positive linear functionals majorized by $\omega$ are of the form $\lambda \omega$, with $0 \leq \lambda \leq 1$. By [BR87], Theorem 2.3.15, we are allowed to use the terms pure and extremal interchangeably. When (2.11) does not hold, it is natural to consider $\omega$ as a mixture of two pure phases $\omega_1$ and $\omega_2$, with proportions $\lambda$ and $(1 - \lambda)$, respectively.

Thermal states $\omega_{\beta,\mu}$ satisfy the equilibrium (KMS) condition ([BR97], [Hug72]) and will be called KMS or thermal equilibrium states, or, for short, thermal states. The commutant $\pi_\omega(A)'$ of $\pi_\omega(A)$ is defined as $\pi_\omega(A)' = \{B \in B(H_\omega) : [A,B] = 0 \forall A \in \pi_\omega(A)\}$. the strong closure of $\pi_\omega(A)$, called the von Neumann algebra generated by $\pi_\omega(A)$, which also equals $\pi_\omega(A)''$ by von Neumann’s theorem [BR87], is called a factor if its center

$$Z_\omega = \pi_\omega(A)' \cap \pi_\omega(A)^{''},$$ (2.12)

is a multiple of the identity operator

$$Z_\omega = \{C \mathbb{1}\}.$$ (2.13)
The corresponding representation is called **factor** or **primary**, and the extension of \( \omega \) to \( \pi_\omega(A) \) is called a factor or primary state. Consider the central decomposition of a KMS state \( \omega_\beta \) [BR87] (we omit the \( \mu \) for brevity):

\[
\omega_\beta(A) = \int_{E_\beta^A} d\mu(\omega'_\beta)\omega'_\beta(A),
\]

which, for a KMS state is identical to the extremal or ergodic decomposition, see Theorem 4.2.10 of [BR87]. The states \( \omega'_\beta \) in (2.14) are extremal or factor states, and the decomposition is along the center \( Z_{\omega_\beta} \) which is of the form (2.13). In the examples we shall treat, \( Z_{\omega_\beta} \) coincides with the so-called **algebra at infinity** ([BR87], Example 4.2.11). Let \( \omega \) be a spatially (\( \mathbb{Z}^d \) - or \( \mathbb{R}^d \)) - translation invariant state (we shall no longer distinguish these two possibilities explicitly):

\[
\omega(\tau_x(A)) = \omega(A) \quad \forall A \in \mathcal{A}, \forall x,
\]

where \( \tau_x \) denotes the group of automorphisms of \( \mathcal{A} \) corresponding to translations. Let us define

\[
\eta(A) := s - \lim_{V \to \infty} \eta_\Lambda(A),
\]

(2.16)

where

\[
\eta_\Lambda(A) = \frac{1}{V} \int_\Lambda dx \pi_\omega(\tau_x(A)),
\]

(2.17)

again not distinguishing the lattice from the continuous case, in the former one has a sum instead of the integral in (2.17). The existence of (2.16) is well-known, see [BR97], or Proposition 6.7 in [MW13]. Then by construction \( \eta(A) \in Z_\omega \). If \( \omega \) is an extremal (=factor=primary), which is also ergodic for space translations, then (2.13) holds and therefore

\[
\eta(A) = \omega(A) 1.
\]

Hence, the states occurring in the extremal or ergodic decomposition of a KMS state correspond to ”freezing” the observables at infinity to their expectation values. In correspondence with (2.16), we extend (2.5) to space averages by

\[
\omega_{\beta,\mu}(\prod_{i=1}^m \eta(A_i)B) = \lim_{V \to \infty} \omega_{\beta,\mu,\Lambda}(\prod_{i=1}^m \eta_\Lambda(A_i)B) = \lim_{V \to \infty} \omega_{\beta,\mu}(\prod_{i=1}^m \eta_\Lambda(A_i)B).
\]

(2.19)

Here we assumed that \( \omega_{\beta,\mu,\Lambda} \) is space translation-invariant, which may be achieved by imposing the periodic b.c. on \( \Lambda \).

Let, now, \( G \) be a group, \( \{\tau_g\} \) denote the corresponding group of \( * \)-automorphisms of \( \mathcal{A} \), and assume that \( \tau_g \circ \tau_x = \tau_x \circ \tau_g \) for all \( g \in G \) and \( x \), i.e., \( G \) commutes with space translations. We assume henceforth that all states are space translation-invariant, (2.15), and thus all states in decomposition (2.14) are also invariant under space translations.

**Definition 2.2.** We say that the state \( \omega \) undergoes a (**conventional**) Spontaneous Symmetry Breaking (SSB) of the group \( G \) if:

(i) \( \omega \) is \( G \)-invariant, i.e., (2.8)-(2.10) hold;
(ii) $\omega$ has a nontrivial decomposition \((2.14)\) into ergodic states $\omega'_\beta$, which means that at least two such distinct states occur in representation \((2.14)\), and

$$\omega'_\beta(\tau_g(A)) \neq \omega'_\beta(A) ,$$

for some $g \in G$, and for some $A \in \mathcal{A}$.

As previously remarked, we shall use the W* description: $\mathcal{A}$ shall henceforth be identified with the von neumann algebra $\pi_\omega(A)''$ corresponding to a given state $\omega$; thus, $\eta(A)$ is a special element of $\mathcal{A}$.

Note that if there is no nontrivial decomposition, then there exists only one equilibrium state, which is then automatically $G$-invariant.

The physical interpretation of condition (ii) in Definition 2.2 is well-known (see \cite{Sew86}, or \cite{Rue69}). By \((2.18)\), for an ergodic state $\omega'$ in \((2.14)\),

$$\lim_{V \to \infty} \frac{1}{V} \int_{\Lambda} dx \omega'(\tau_x(A)B) = \omega'(A) \omega'(B) \quad \forall A, B \in \mathcal{A} .$$

By \((2.13)\) and \((2.21)\), the spatial averages do not fluctuate in an ergodic state $\omega'$:

$$\lim_{V \to \infty} \omega' \left\{ \left( \frac{1}{V} \int_{\Lambda} dx \tau_x(A) \right)^2 - \left( \frac{1}{V} \int_{\Lambda} dx \omega'(\tau_x(A)) \right)^2 \right\} = 0 .$$

This is a characteristic property of a pure thermodynamic phase, in which average values, such as the density, do not fluctuate (in contrast to a mixture).

How does this relate to SSB ? The part (ii) of Definition 2.2 implies that $\tau_g$ cannot be implemented by a group of unitary operators in $\mathcal{H}_\omega$ in the form \((2.10)\), in particular suitable generators of the unitary group do not exist. A natural alternative to \((2.21)\) is to replace it (see \cite{Swi70}, \cite{Wre87}) by

$$\lim_{R \to \infty, \delta \to 0} \omega'_\beta([Q_{R,\delta}, A]) \neq 0 \text{ for some } A \in \mathcal{A}_L .$$

Here $\mathcal{A}_L$ is the dense subalgebra of local observables, and $Q_{R,\delta}$ is a smooth approximation to the charge in space and time, i.e.,

$$Q_{R,\delta} := \int dx dt f_R(x) f_\delta(t) j^0(x, t) ,$$

with $\lim_{|x| \to \infty} f_R(x) = 1$, $f_\delta$ tends to delta-function as $\delta \to 0$, and $j^0(x, t)$ is the "charge density". In statistical mechanics one may ignore time-smoothing, and choose $f_R$ as characteristic function of a region $\Lambda$. The limit \((2.23)\) exists as a consequence of locality \cite{Swi70}. For quantum statistical mechanics one uses the property of "causality" $[\mathcal{A}_\Lambda, \mathcal{A}_{\Lambda'}] = 0$ if $\Lambda \cap \Lambda' = \emptyset$.

To illustrate the ideas presented above we recall a standard example of quantum spin systems corresponding to the simplest Heisenberg ferromagnet

$$H_\Lambda = - \sum_{x,y \in \Lambda; \|x-y\|=1} \sigma_x \cdot \sigma_y ,$$

7

\[\text{Equation (2.25)}\]
where $\sigma^i_x, i = 1, 2, 3$ are the Pauli matrices at $x$, on the Hilbert space $H_\Lambda = \otimes_{x \in \Lambda} C_2^x$. Assuming that $H_\Lambda$ in (2.25) is defined with periodic b.c., so that the momentum is also well-defined, the Gibbs state $\omega_{\beta,\Lambda}$ in (2.1) (with $\mu = 0$) is invariant under the rotation group $G = SO(3)$. Hence, $\omega_{\beta}$ satisfies (2.8) with $G = SO(3)$, and, moreover, (2.15) also holds by translation invariance of $\omega_{\beta,\Lambda}$.

The "charge" (2.24) coincides with magnetisation

$$Q_\Lambda = M_\Lambda = \sum_{x \in \Lambda} \sigma^x_x.$$  
(2.26)

In an ergodic state the spatial average (2.16), (2.17) of the observable $\sigma$,

$$\eta(\sigma) = s \lim_{V \to \infty} \left( \eta_\Lambda = \frac{1}{V} \sum_{x \in \Lambda} \sigma^x_x \right),$$  
(2.27)

is equal by (2.18) to

$$\eta(\sigma) = \lambda n,$$  
(2.28)

where $n$ is a fixed unit vector and coefficient $\lambda = \lambda(\beta, \mu)$. Note that a rotation $g = R \in G$ acts on $n$, by (2.27), (2.28), in the form

$$\tau_g(\eta(\sigma)) = \lambda R n.$$  
(2.29)

Since (2.14) is a central decomposition, for the Gibbs state we may write it in the form

$$\omega_{\beta}(A) = \int d\mu_n \omega_{\beta,n}(A),$$  
(2.30)

where $\mu$ is the normalized measure on the sphere $S_2$ and each $\omega_{\beta,n}$ is ergodic. Further,

$$\omega_{\beta,n}(\tau_g(A)) = \omega_{\beta,n}(\tau_g(\eta(A))) = \omega_{\beta,Rn}(\eta(A)).$$  
(2.31)

Now we recall the concept of Off-Diagonal Long Range Order (ODLRO), which is relevant to our discussion of SSB in the Heisenberg ferromagnet: in this definition $\omega_\beta$ is assumed to be an equilibrium state of the Heisenberg ferromagnet (2.25): for a discussion of other examples, see remark 2.5.

**Definition 2.3.** For a given $\beta$ the state $\omega_\beta$ is said to exhibit ODLRO if

$$\lim_{V \to \infty} \omega_\beta(\eta_\Lambda(\sigma)^2) > 0.$$  
(2.32)

Since $\eta_\Lambda$ is given by (2.17), the both $\sigma$ and $\eta_\Lambda(\sigma)$ are three-component vectors, and $(\eta_\Lambda(\sigma))^2 = ||\eta_\Lambda(\sigma)||^2$. Hence, the space-averaged magnetization: $\eta$ (2.27), fluctuates in the state $\omega_\beta$. The following well-known proposition relates ODLRO and SSB for the Heisenberg ferromagnet:

**Proposition 2.1.** If $\omega_\beta$ exhibits conventional ODLRO, it undergoes the SSB defined by (2.20), with $A$ defined by (2.27). Conversely, if (2.20) holds for some $\omega_{\beta,n}$ in the decomposition (2.30), with $A$ given by (2.27), then (2.32) holds.
Proof. If $\omega_\beta$ exhibits ODLRO, it follows from (2.21) and (2.28) that $\lambda \neq 0$ in (2.28), and thus the ergodic decomposition (2.30) is nontrivial. Hence, SSB holds, with $A$ in (2.20) given by $\eta(A)$, defined by (2.27). The converse statement is a direct consequence of the ergodicity of $\omega_{\beta,n}$, and the fact that (2.20) implies that $\lambda \neq 0$. \qed

Remark 2.4. The ergodic states are not invariant under $G = SO(3)$ but rather under the isotropy (stationary) subgroup $H_{n_0}$ of $G$, and $S_{d-1}$ may be identified as the harmonic space $G/H$.

Remark 2.5. The connection between ODLRO and the existence of several equilibrium states for quantum spin systems was first pointed out by Dyson, Lieb and Simon in their seminal paper [DLS], see also the review by Nachtergaele [Ntg] and references given there. By [DLS], both the spin one-half XY model for $\beta \geq \beta^c_1$ and the Heisenberg antiferromagnet for suitable spin and $\beta \geq \beta^c_2$, with $\beta^c_1, \beta^c_2$ explicitly given in [DLS], display ODLRO in the sense of definition 2.3, but with different $\eta_\Lambda$ in (2.27) (for the antiferromagnet the sum over $x \in \Lambda$ being replaced by a sum over $\Lambda \cap A$, where $Z^d = A \cup B$, $A$ and $B$ being disjoint sublattices. We expect that proposition 2.1 is applicable to the above mentioned cases, yielding SSB (of the rotation group $(SO(2)$ in the XY case) according to Definition 2.2, but a choice of $\eta_\Lambda$ for a general Heisenberg hamiltonian, with arbitrary spin, is not known, as well as what the correct order parameters are, and how the set of pure phases should be parametrized and constructed (We thank B. Nachtergaele for this last remark). We therefore restrict ourselves to the ferromagnet as our quantum spin example.

Remark 2.6. By (2.28) we have different values for the ”charge density” $\eta(\sigma)$ labelled by $n \in S_2$. By a well-known result (see, e.g., [MW13], Corollary 6.3), the GNS representations $\pi_{\omega_n}$ associated to the corresponding states $\omega_n$ in the (central) decomposition (2.30) are not unitary equivalent (they are, more precisely, disjoint, see Definition 6.6 in [MW13]), and the GNS Hilbert space splits into a direct integral of disjoint ”sectors” $H_n$ (see e.g. [BR87]).

We note that in this respect the case of boson systems is more complicated than spin lattice systems. It becomes clear even on the level of the perfect Bose-gas.

To see this, consider the Perfect Bose-gas (PBG) in a three-dimensional anisotropic parallelepiped $\Lambda := V^{\alpha_1} \times V^{\alpha_2} \times V^{\alpha_3}$, with periodic boundary condition (p.b.c.) and $\alpha_1 \geq \alpha_2 \geq \alpha_3$, $\alpha_1 + \alpha_2 + \alpha_3 = 1$, i.e. the volume $|\Lambda| = V$. In the boson Fock space $\mathcal{F} := \mathcal{F}_{\text{boson}}(L^2(\Lambda))$ the Hamiltonian of this system for the grand-canonical ensemble with chemical potential $\mu < 0$ is defined by:

$$H^0_\Lambda(\mu) = T_\Lambda - \mu N_\Lambda = \sum_{k \in \Lambda^*} (\varepsilon_k - \mu) b_k^* b_k. \tag{2.33}$$

Here one-particle kinetic-energy operator spectrum $\{\varepsilon_k = k^2\}_{k \in \Lambda^*}$, where the dual to $\Lambda$ set is:

$$\Lambda^* = \{k_j = \frac{2\pi}{V^{\alpha_j}} n_j : n_j \in \mathbb{Z}\}_{j=1}^{d=3} \text{ then } \varepsilon_k = \sum_{j=1}^d k_j^2. \tag{2.34}$$

We denote by $b_k := b(\phi_k^\Lambda)$ and $b_k^* := b^*(\phi_k^\Lambda)$ the boson annihilation and creation operators in the Fock space $\mathcal{F}$. They are indexed by the ortho-normal basis $\{\phi_k^\Lambda(x) = e^{ikx}/\sqrt{V}\}_{k \in \Lambda^*} \subset$
$L^2(\Lambda)$ generated by the eigenfunctions of the self-adjoint one-particle kinetic-energy operator \((-\Delta)_{p.b.c.}\) in $L^2(\Lambda)$. Formally these operators satisfy the Canonical Commutation Relations (CCR): $[b_k, b_{k'}^*] = \delta_{k,k'}$. Then $N_k = b_k^*b_k$ is occupation-number operator of the one-particle state $\phi_k^\Lambda$ and $N_\Lambda = \sum_{k \in \Lambda^*} N_k$ denotes the total-number operator in $\Lambda$.

If we denote by $\omega^0_{\beta,\mu,\Lambda}(\cdot)$ the grand-canonical Gibbs state of the PBG generated by (2.33), then the problem of existence of conventional Bose-Einstein condensation is related to solution of the equation

$$\rho = \frac{1}{V} \sum_{k \in \Lambda^*} \omega^0_{\beta,\mu,\Lambda}(N_k) = \frac{1}{V} \sum_{k \in \Lambda^*} e^{\beta(\varepsilon_k - \mu)} - 1$$

for a given total particle density $\rho$ in $\Lambda$. Note that by (2.34) the thermodynamic limit $\Lambda \uparrow \mathbb{R}^3$ in the right-hand side of (2.35)

$$\mathcal{I}(\beta, \mu) = \lim_{\Lambda} \frac{1}{V} \sum_{k \in \Lambda^*} \omega^0_{\beta,\mu,\Lambda}(N_k) = \frac{1}{(2\pi)^3} \int_{\mathbb{R}^3} d^3k \frac{1}{e^{\beta(\varepsilon_k - \mu)} - 1}$$

exists for any $\mu < 0$. It reaches its (finite) maximal value $\mathcal{I}(\beta, \mu = 0) = \rho_c(\beta)$, which is called the critical particle density for a given temperature.

The existence of finite $\rho_c(\beta)$ triggers (via saturation mechanism) a non-zero BEC $\rho_0(\beta) := \rho - \rho_c(\beta)$, when the total particle density $\rho > \rho_c(\beta)$.

Note that for $\alpha_1 < 1/2$, the whole condensate is sitting in the one-particle ground state mode $k = 0$:

$$\rho_0(\beta) = \rho - \rho_c(\beta) = \lim_{\Lambda} \frac{1}{V} \omega^0_{\beta,\mu,\Lambda}(N_0) = \lim_{\Lambda} \frac{1}{V} \left\{ e^{-\beta \mu \Lambda(\beta,\rho \geq \rho_c(\beta))} - 1 \right\}^{-1}$$

$$\mu_\Lambda(\beta, \rho \geq \rho_c(\beta)) = -\frac{1}{V} \frac{1}{\beta(\rho - \rho_c(\beta))} + o(1/V) ,$$

where $\mu_\Lambda(\beta, \rho)$ is a unique solution of equation (2.35).

This is a well-known conventional (or the type I [vdBLP]) condensation. In particular, in this case it make sense the ODLRO for the Bose-field

$$b(x) = \sum_{k \in \Lambda^*} b_k \phi_k^\Lambda(x) .$$

Indeed, by Definition (2.35) one gets for the spacial average of (2.37)

$$\lim_{\Lambda} \omega^0_{\beta,\mu,\Lambda}(\frac{1}{V} \int_{\Lambda} dx b^*(x) \frac{1}{V} \int_{\Lambda} dx b(x)) = \lim_{\Lambda} \omega^0_{\beta,\mu,\Lambda}(\frac{b^*_0b_0}{V}) = \rho_0(\beta) ,$$

i.e. the ODLRO coincides with the condensate density [Ver11].

For $\alpha_1 = 1/2$ (the Casimir box [ZB01]) one observes the infinitely-many levels macroscopic occupation called the type II condensation.

On the other hand, when $\alpha_1 > 1/2$ (van den Berg-Lewis-Pulé boxe [vdBLP]) one obtains

$$\lim_{\Lambda} \omega^0_{\beta,\mu,\Lambda}(\frac{b_k^*b_k}{V}) = \lim_{\Lambda} \frac{1}{V} \left\{ e^{\beta(\varepsilon_k - \mu \Lambda(\beta,\rho))} - 1 \right\}^{-1} = 0 , \forall k \in \Lambda^* ,$$

i.e. the ODLRO coincides with the condensate density [Ver11].

For $\alpha_1 = 1/2$ (the Casimir box [ZB01]) one observes the infinitely-many levels macroscopic occupation called the type II condensation.

On the other hand, when $\alpha_1 > 1/2$ (van den Berg-Lewis-Pulé boxe [vdBLP]) one obtains

$$\lim_{\Lambda} \omega^0_{\beta,\mu,\Lambda}(\frac{b_k^*b_k}{V}) = \lim_{\Lambda} \frac{1}{V} \left\{ e^{\beta(\varepsilon_k - \mu \Lambda(\beta,\rho))} - 1 \right\}^{-1} = 0 , \forall k \in \Lambda^* ,$$

i.e. the ODLRO coincides with the condensate density [Ver11].
i.e., there is no macroscopic occupation of any mode for any value of particle density \( \rho \). But a generalised BEC (gBEC of type III) does exist in the following sense:

\[
\rho - \rho_c(\beta) = \lim_{\eta \to +0} \lim_{V \to \infty} \frac{1}{V} \sum_{\{k \in \Lambda^*, \|k\| \leq \eta\}} \left\{ e^{\beta(\epsilon_k - \mu(\beta, \rho))} - 1 \right\}^{-1}, \text{ for } \rho > \rho_c(\beta) .
\]

Note that (2.38) and (2.39) imply triviality of the ODLRO, whereas the condensation in the sense (2.40) is nontrivial.

We comment that this unusual condensation is not exclusively due to the special geometry \( \alpha_1 > 1/2 \). In fact the same phenomenon of the gBEC (type III) happens due to interaction in the model with Hamiltonian [BZ01]:

\[
H_\Lambda = \sum_{k \in \Lambda^*} \varepsilon_k b_k^* b_k + \frac{a}{2V} \sum_{k \in \Lambda^*} b_k^* b_k^* b_k b_k , \ a > 0 .
\]

These examples show that connection between BEC, ODLRO, and SSB is a subtle matter. This motivates and bolsters a relevance of the Bogoliubov quasi-average method [Bog07]–[Bog70], that we discuss in the next two sections.

3 Selection of pure states by the Bogoliubov quasi-averages: spin systems

Considering further the simple example of spin system (2.25) for the sake of argument, at least two methods of selecting pure states may be suggested: (1) by taking in (2.1), (2.2) \( H_\Lambda \) with special boundary conditions (b.c.), i.e., upon imposing on the boundary \( \partial \Lambda \) of \( \Lambda \)

\[
|n\rangle_x \text{ such that } \sigma_x |n\rangle_x = |n\rangle_x
\]

The above choice leads, presumably, to the limiting states \( \omega_{\beta,n} \) in (2.30); (2) by replacing in (2.1), (2.2) \( H_\Lambda \) by the quasi-Hamiltonian

\[
H_{\Lambda,B} := H_\Lambda + H_B^B ,
\]

with the symmetry-breaking vector field \( B n \) directed along the unit vector \( n \):

\[
H_B^B = -B n \cdot \sum_{x \in \Lambda} \sigma_x , \ B > 0 .
\]

We take \( B \to +0 \) after the thermodynamic limit \( V \to \infty \). This method, which is known as the Bogoliubov quasi-averages ([Bog07]–[Bog70], [ZB01]), is currently employed as a trick, i.e., without explicit connection to ergodic states. The quantity \( \sum_{x \in \Lambda} \sigma_x \) (the magnetization) in the symmetry-breaking field is known as the order parameter. As spelled out in (3.3), it is appropriate to the Heisenberg ferromagnet (2.25) and for the XY model, but not for the antiferromagnet, in which case the order parameter should be replaced by the sub-lattice magnetization \( \sum_{x \in \Lambda \cap \Lambda} \sigma_x \), where \( \mathbb{Z}^d = A \cup B \), \( A, B \) denoting two disjoint sublattices.
If we consider first $0 < \beta < \infty$, $G = SO(3)$ and $H_\Lambda$ the Hamiltonian (2.25) (or its antiferromagnetic or XY analog), with free or periodic b.c., then $H_\Lambda$ is $G$-invariant, and thus $\omega_{\beta,\Lambda}$, defined by (2.1), (2.2), is also $G$-invariant. Taking, now, $H_\Lambda$ with the b.c. (3.1), both $H_\Lambda$ and $\omega_{\beta,\Lambda}$ are not $G$-invariant. Consider, now, $\beta = \infty$, i.e., the ground state, with $H_\Lambda$ given by (2.25), defined with free or periodic b.c.. Again, $H_\Lambda$ is invariant under $G$, and we may regard a ground state

$$\omega_{\infty,\Lambda} = (\Omega_\Lambda, \cdot \Omega_\Lambda)),$$

with

$$|\Omega_\Lambda = \otimes_{x\in\Lambda} |n_x\rangle.$$

Then, clearly, $\omega_{\infty,\Lambda}$ as well as its infinite volume counterpart is not $G$-invariant. Note that (3.1) leads, however, presumably to the ergodic states $\omega_{\infty,\Lambda}$ in the decomposition (2.30), when taking the weak* limit as $\Lambda \rightarrow \mathbb{Z}^3$.

If we take, however, the weak* limit, as $\beta \rightarrow \infty$ along a subsequence, of $\omega_{\beta}$, it may be conjectured that the $G$-invariant ground state

$$\omega_{\infty} := \int d\mu_\eta \omega_{\infty,\eta},$$

is obtained. The limits $V \rightarrow \infty$ and $\beta \rightarrow \infty$ are not expected to commute, and we believe, in consonance with the third principle of thermodynamics [WA09], that it is more adequate, both physically and mathematically, to regard the states $\omega_{\beta}$ for $0 < \beta < \infty$ as fundamental, with ground states defined as their (weak*) limit as $\beta \rightarrow \infty$ (along a subsequence or subnet). In this sense, the assertion found in most textbooks, see also [SY07] beginning of Section 2, that SSB occurs when the Hamiltonian is invariant, but not the state, is not correct, or, at least, not precise. Note, however, that, in the textbooks, "state" is understood as the ground state or the vacuum state, but not as the thermal state, for which the equivalence between the invariance of the Hamiltonian and the state is essentially obvious.

If one uses the method of Bogoliubov quasi-averages, such difficulties do not appear, because $\omega_{\beta,\eta}$ is thereby directly connected to $\omega_{\infty,\eta}$ for each $\eta$. Moreover, as we motivated at the end of Section 2 by the example of gBEC, the quasi-average method is even indispensable for quantum continuous Bose-systems. An example of its use appears in the next Section 4. See also the conclusion.

Note that for quantum continuous many-body systems or relativistic quantum field theory imposition of boundary conditions is very questionable, or even not feasible.

The proof of (2) for the ferromagnet follows [SY07], but using Bloch coherent states, instead of Glauber coherent states, in the manner of Lieb’s classic work on the classical limit of quantum spin systems [Lie73]. It will not be spelled out here, because the next section will be devoted to a similar proof in the case $G = U(1)$ and Boson systems, but we note the result:

**Proposition 3.1.** The ergodic states $\omega_{\beta,\Lambda}$ in the decomposition (2.30) may be obtained by the Bogoliubov quasi-average method:

$$\omega_{\beta,\Lambda} = \lim_{B \rightarrow \infty} \lim_{V \rightarrow \infty} \omega_{\beta,\Lambda,\eta},$$

12
where
\[
\omega_{\beta,n}(A) \equiv \frac{\text{Tr}_{H_N}(\exp(-\beta H_{A,B})A)}{\text{Tr}_{H_N}(\exp(-\beta H_{A,B}))},
\]  
(3.7)

with \(A \in \mathcal{B}(H_N)\), and \(H_{A,B}\) is defined by (3.2), (3.3) for the ferromagnet (2.25). The limit (3.6) is taken along a (double) subsequence of the variables \((B, V)\). For \(A\) of the form (2.27), the actual double limit in (3.6) exists, and, if ODLRO holds in the form (2.32), SSB in the form of definition 2.2 holds for the states (3.6).

The identification of \(\omega_{\beta,n}\) in (3.6) with those occurring in the decomposition (2.30) is possible by the unicity of the ergodic decomposition, in view of the fact that the spin algebra is asymptotically abelian for the space translations, see [BR87], pp 380,381. Since for KMS states the ergodic decomposition coincides with the central decomposition, the extension of the states to elements of the center is also unique.

4 Continuous boson systems: quasi-averages, condensates, and pure states

We now study the states of Boson systems, and, for that matter, assume, together with Verbeure ([Ver11], Ch.4.3.2) that they are analytic in the sense of [BR97], Ch.5.2.3. We start, with [SY07], with the Hamiltonian for Bosons in a cubic box \(\Lambda\) of side \(L\) and volume \(V = L^3\),
\[
H_{\Lambda,\mu} = H_{0,\Lambda,\mu} + V_{\Lambda},
\]  
(4.1)

where
\[
V_{\Lambda} = \frac{1}{V} \sum_{k,p,q} \nu(p) b_{k+p}^* b_{q-p} b_k b_q,
\]  
(4.2)

with periodic b.c., \(h = 2m = 1\), and \(k, p, q \in \Lambda^*\). Here \(\Lambda^*\) is dual (with respect to Fourier transformation) set corresponding to \(\Lambda\). Here \(\nu\) is the Fourier transform of the two-body potential \(v(x)\), with bound
\[
|\nu(k)| \leq \phi < \infty,
\]  
(4.3)

and
\[
H_{0,\Lambda,\mu} = \sum_k k^2 b_k^* b_k - \mu N_{\Lambda},
\]  
(4.4)

\[
N_{\Lambda} = \sum_k b_k^* b_k,
\]  
(4.5)

with \([b_k, b_l^*] = \delta_{k,l}\) the second quantized annihilation and creation operators. The quasi-Hamiltonian corresponding to (3.2) is taken to be
\[
H_{\Lambda,\mu,\lambda} = H_{\Lambda,\mu} + H_{\Lambda}^\lambda,
\]  
(4.6)

with the symmetry-breaking field analogous to (3.3) given by
\[
H_{\Lambda}^\lambda = \sqrt{V}(\lambda \phi b_0 + \bar{\lambda} \phi b_0^*).\]  
(4.7)
Above,
\[ \lambda_\phi = \lambda \exp(i\phi) \quad \text{with} \quad \lambda \geq 0, \quad \text{where} \quad \text{arg}(\lambda) = \phi \in [0, 2\pi). \] (4.8)
We take initially \( \lambda \geq 0 \) and consider first the perfect Bose-gas to define
\[ H_{0,\Lambda,\mu,\lambda} = H_{0,\Lambda,\mu} + H^\lambda_\Lambda. \] (4.9)
We may write
\[ H_{0,\Lambda,\mu,\lambda} = H_0 + H_k \neq 0, \]
where \( H_0 = -\mu b_0^* b_0 + \sqrt{V}(\lambda_\phi b_0 + \lambda_\phi b_0^*) \). The grand partition function \( \Xi_\Lambda \) splits into a product over the zero mode and the remaining modes. We introduce the canonical shift transformation
\[ \hat{b}_0 := b_0 + \frac{\lambda_\phi \sqrt{V}}{\mu}, \] (4.10)
without altering the nonzero modes, and assume henceforth \( \mu < 0 \). We thus obtain for the grand partition function \( \Xi_\Lambda \),
\[ \Xi_\Lambda(\beta, \mu, \lambda) = (1 - \exp(\beta\mu))^{-1} \exp\left(-\frac{\beta|\lambda|^2V}{\mu}\right) \Xi'_\Lambda, \] (4.11)
where
\[ \Xi'_\Lambda := \prod_{k \neq 0} (1 - \exp(-\beta(\epsilon_k - \mu)))^{-1}, \] (4.12)
with \( \epsilon_k = k^2 \). Recall that the grand-canonical state for the perfect Bose-gas is
\[ \omega^0_{\beta,\mu,\Lambda,\lambda}(\cdot) := \frac{1}{\Xi_\Lambda} \text{Tr}[e^{-\beta H_{0,\Lambda,\mu,\lambda}(\cdot)}], \] (4.13)
see Section 2. Then it follows from (4.11)-(4.13) that the mean density \( \rho \) equals to
\[ \rho = \omega_{\beta,\mu,\Lambda,\lambda}(\frac{N_\Lambda}{V}) = \frac{1}{V(\exp(-\beta\mu) - 1)} + \frac{|\lambda|^2}{\mu^2} + \frac{1}{V \sum_{k \neq 0} \exp(\beta(\epsilon_k - \mu)) - 1}. \] (4.14)
Equation (4.14) is the starting point of our analysis. Let
\[ \rho_c(\beta) \equiv \int \frac{dk}{2\pi^2} (\exp(\beta\epsilon_k) - 1)^{-1}. \] (4.15)

**Lemma 4.1.** Let \( 0 < \beta < \infty \) be fixed. Then, for each
\[ \rho_c < \rho < \infty, \] (4.16)
and for each \( \lambda > 0, V < \infty \), there exists a unique solution of (4.14) of the form
\[ \mu(V, |\lambda|, \rho) = -\frac{|\lambda|}{\sqrt{\rho - \rho_c(\beta)}} + \alpha(|\lambda|, V), \] (4.17)
with
\[ \alpha(|\lambda|, V) \geq 0 \quad \forall \quad |\lambda|, V, \] (4.18)
and such that
\[ \lim_{|\lambda| \to 0} \lim_{V \to \infty} \frac{\alpha(|\lambda|, V)}{|\lambda|} = 0. \] (4.19)
Remark 4.2. We skip the proof of this lemma, but we note that besides the cube $\Lambda$, it is also true for the case of three-dimensional anisotropic parallelepiped $\Lambda := V^{\alpha_1} \times V^{\alpha_2} \times V^{\alpha_3}$, with periodic boundary condition (p.b.c.) and $\alpha_1 \geq \alpha_2 \geq \alpha_3$, $\alpha_1 + \alpha_2 + \alpha_3 = 1$, i.e. the volume $|\Lambda| = V$.

We have now that
\[
\lim_{\lambda \to +0} \lim_{V \to \infty} \omega_0^{0,\beta,\mu,\lambda,\lambda}(\eta_\lambda(b_0^*)) = \lim_{\lambda \to +0} \lim_{V \to \infty} \frac{\partial}{\partial \lambda} p_{\beta,\mu,\lambda,\lambda} , \quad (4.20)
\]
where $\eta$ is defined as in (2.16), (2.17). Above we denote by
\[
p_{\beta,\mu,\lambda} = \frac{1}{\beta V} \ln \Xi_{\Lambda}(\beta, \mu, \lambda) , \quad (4.21)
\]
the pressure. By (4.14), (4.21) and the fact that the second term in (4.14) equals $(\lambda_\phi \bar{\lambda}_\phi)/\mu^2$, we obtain
\[
\frac{\partial}{\partial \lambda} p_{\beta,\mu,\lambda,\lambda} = -\frac{\bar{\lambda}_\phi}{\mu} . \quad (4.22)
\]

By (4.22), (4.17) and (4.20),
\[
\lim_{\lambda \to +0} \lim_{V \to \infty} \omega_0^{0,\beta,\mu,\lambda,\lambda}(\eta_\lambda(b_0^*)) = \sqrt{\rho_0} \exp(i\phi) , \quad (4.23)
\]
where, for the perfect Bose-gas,
\[
\rho_0 = \rho - \rho_c(\beta) .
\]

We see therefore that the phase in (4.20) remains in (4.23) even after the limit $\lambda \to +0$. Define the states
\[
\omega_0^{0,\beta,\mu,\phi} := \lim_{\lambda \to +0} \lim_{V \to \infty} \omega_0^{0,\beta,\mu,\lambda,\lambda} , \quad (4.24)
\]
where the double limit along a subnet exists by weak* compactness [Hug72], [BR87].

For this and the forthcoming definitions, we are referring to the full interacting Bose gas (4.5)-(4.3), with $\omega$ replaced by $\omega^0$. The corresponding definitions for the general case of the quantities $\omega_{\beta,\mu,\lambda,\lambda}$, $\omega_{\beta,\mu,\lambda,\phi}$ and $\omega_{\beta,\mu,\phi}$ are the obvious analogues of (4.13) and (4.24), with $H_{0,\Lambda,\mu,\lambda}$ replaced by $H_{\lambda,\mu,\lambda}$.

We say (cf Section 2) that the interacting Bose-gas undergoes the zero-mode Bose-Einstein condensation (BEC) (and/or ODLRO) if
\[
\lim_{V \to \infty} \omega_{\beta,\mu,\lambda}(\frac{b_0^* b_0}{V}) = \rho_0 > 0 . \quad (4.25)
\]

We define the group of gauge transformations $\{\tau_\lambda | \lambda \in [0, 2\pi)\}$ by the operations
\[
\tau_\lambda(b^*(f)) = \exp(i\lambda)b^*(f)\tau_\lambda(b(f)) = \exp(-i\lambda)b(f) , \quad (4.26)
\]
where $b^*(f), b(f)$ are the creation and annihilation operators smeared over test-functions $f$ from the Schwartz space. This group is isomorphic to the group $U(1)$.

Note that (4.23), (4.24) show that the states $\omega_{\beta,\mu,\phi}$ are not gauge invariant. Assuming that they are the ergodic states in the ergodic decomposition of $\omega_{\beta,\mu}$, which we shall prove
next, in greater generality, for the interacting system, it follows that BEC is equivalent to SSB for the free Bose gas. It is illuminating to see, however, in the free case, a different explicit mechanism for the appearance of the phase, which is connected with (4.17) of Lemma 4.5, i.e., that the chemical potential remains proportional to $|\lambda|$ even after the thermodynamic limit (together with (4.22)). This property persists for the interacting system, see below.

**Remark 4.3.** Note that these results are independent of the anisotropy, i.e., of whether the condensation for $\lambda = 0$ is in single mode ($k = 0$) or it is extended as the gBEC-type III, Section 2. This means that the Bogoliubov quasi-average method solves the question about equivalence between (BEC)$_{qa}$, (SSB)$_{qa}$ and (ODLRO)$_{qa}$ if they are defined via one-mode quasi-average.

To this aim we re-consider the prefect Bose-gas (2.33) with symmetry breaking sources (4.7) in a single mode $q \in \Lambda^*$:

$$H^0_{\Lambda}(\mu; \eta) := H^0_{\Lambda}(\mu) + \sqrt{V} \left( \eta b_q + \eta^* b^*_q \right), \mu < 0. \quad (4.27)$$

Then for a fixed density $\rho$, the the grand-canonical condensate equation (2.35) for (4.27) takes the following form:

$$\rho = \rho_{\Lambda}(\beta, \mu, \eta) := \frac{1}{V} \sum_{k \in \Lambda^*} \omega^0_{\beta, \mu, \eta}(b^*_k b_k) = \frac{1}{V} (e^{\beta(\varepsilon_q - \mu)} - 1)^{-1} + \frac{1}{V} \sum_{k \in \Lambda^* \setminus q} e^{\beta(\varepsilon_k - \mu)} - 1 + \frac{\eta^2}{(\varepsilon_q - \mu)^2}. \quad (4.28)$$

According the quasi-average method, to investigate a possible condensation, one must first take the thermodynamic limit in the right-hand side of (4.28), and then switch off the symmetry breaking source: $\eta \to 0$. Recall that the critical density, which defines the threshold of boson saturation is equal to $\rho_c(\beta) = I(\beta, \mu = 0) \quad (2.36)$, where $I(\beta, \mu) = \lim_{\Lambda} \rho_{\Lambda}(\beta, \mu, \eta = 0)$.

Since $\mu < 0$, we have to distinguish two cases:

(i) Let $q \in \Lambda^*$ be such that $\lim_{\Lambda} \varepsilon_q > 0$, we obtain from (4.28) the condensate equation

$$\rho = \lim_{\eta \to 0} \lim_{\Lambda} \rho_{\Lambda}(\beta, \mu, \eta) = I(\beta, \mu),$$

i.e. the quasi-average coincides with the average. Hence, we return to the analysis of the condensate equation (4.28) for $\eta = 0$. This leads to finite-volume solutions $\mu_{\Lambda}(\beta, \rho)$ and consequently to all possible types of condensation as a function of anisotropy $\alpha_1$, see Section 2 for details.

(ii) On the other hand, if $q \in \Lambda^*$ is such that $\lim_{\Lambda} \varepsilon_q = 0$, then thermodynamic limit in the right-hand side of the condensate equation (4.28) yields:

$$\rho = \lim_{\Lambda} \rho_{\Lambda}(\beta, \mu, \eta) = I(\beta, \mu) + \frac{\eta^2}{\mu^2}. \quad (4.29)$$

Now, if $\rho \leq \rho_c(\beta)$, then the limit of solution of (4.29): $\lim_{\eta \to 0} \mu(\beta, \rho, \eta) = \mu_0(\beta, \rho) < 0$, where $\mu(\beta, \rho, \eta) = \lim_{\Lambda} \mu_{\Lambda}(\beta, \rho, \eta) < 0$ is thermodynamic limit of the finite-volume solution of condensate equation (4.28). Therefore, there is no condensation in any mode.
But if $\rho > \rho_c(\beta)$, then $\lim_{\eta \to 0} \mu(\beta, \rho, \eta) = 0$ and the density of condensate is

$$\rho_0(\beta) = \rho - \rho_c(\beta) = \lim_{\eta \to 0} \frac{|\eta|^2}{\mu(\beta, \rho, \eta)^2}.$$  \hspace{1cm} (4.30)

Note that expectation of the particle density in the $q$-mode (see (4.28)) is

$$\omega_{\beta,\mu,\Lambda,\eta}^0(b_q^* b_q / V) = \frac{1}{V} (e^{\beta(\varepsilon_q - \mu)} - 1)^{-1} + \frac{|\eta|^2}{(\varepsilon_q - \mu)^2}.$$  \hspace{1cm} (4.31)

Then by (4.30) the corresponding Bogoliubov quasi-average for $b_q^* b_q / V$ is equal to

$$\lim_{\eta \to 0} \frac{1}{V} \frac{1}{(e^{\beta(\varepsilon_q - \mu)} - 1)^{-1} + \frac{|\eta|^2}{(\varepsilon_q - \mu)^2}} = 0,$$  \hspace{1cm} (4.32)

i.e., for any $\alpha_1$ the quasi-average condensation (BEC)$_{qa}$ occurs only in one mode (type I), whereas for $\alpha_1 > 1/2$ the BEC is of the type III, see Section 2.

Similarly, diagonalisation (4.10) and (4.30) allow to apply the quasi-average method to calculate a nonvanishing for $\rho > \rho_c(\beta)$ gauge-symmetry breaking (SSB)$_{qa}$:

$$\lim_{\eta \to 0} \frac{\eta}{\mu(\beta, \rho, \eta)} = e^{i \arg(\eta)} \sqrt{\rho - \rho_c(\beta)},$$  \hspace{1cm} (4.33)

along $\{ \eta = |\eta| e^{i \arg(\eta)} | \eta| \to 0 \}$. Then by inspection of (4.31) and (4.33) we find that (SSB)$_{qa}$ and (BEC)$_{qa}$ are equivalent:

$$\lim_{\eta \to 0} \omega_{\beta,\mu,\Lambda,\eta}^0(b_q^* / \sqrt{V}) = \rho - \rho_c(\beta).$$  \hspace{1cm} (4.34)

Note that by (2.35) the (SSB)$_{qa}$ and (BEC)$_{qa}$ are in turn equivalent to (ODLRO)$_{qa}$, whereas for the conventional BEC on gets

$$\lim_{\Lambda} \omega_{\beta,\mu,\Lambda,\eta=0}^0(b_q^* b_q / V) = \lim_{\Lambda} \omega_{\beta,\mu,\Lambda,\eta=0}^0(b_q^* / \sqrt{V}) = 0,$$

for any $\rho$ and $q \in \Lambda^*$ as soon as $\alpha_1 > 1/2$.

We now consider the interacting case (4.1)-(4.5). The famous Bogoliubov approximation of replacing $\eta(\beta)$, $\eta(\beta^*)$ by $c$-numbers [ZB01], [Za14] will be instrumental. It was
proved by Ginibre [Gin68], Lieb, Seiringer and Yngvason ([SY05], [SY07]) and Sütö [S05], but we shall rely on the method of [SY07], which uses the Berezin-Lieb inequality [Lie73].

Let \( z \) be a complex number, \( |z| = \exp(-|z|^2/2 + z b_0^\dagger |0) \) the Glauber coherent vector in \( \mathcal{F}_0 \) and, as in [SY07], let \((H_{\Lambda,\mu,\lambda})' (z)\) be the lower symbol of \( H_{\Lambda,\mu,\lambda} \). Then

\[
\exp(\beta V p'_{\beta,\mu,\lambda}) = \Xi_\Lambda(\beta, \mu, \lambda)' = \int d^2z \text{Tr}_{\mathcal{H}'} \exp(-\beta (H_{\Lambda,\mu,\lambda})'(z)) ,
\]

where \( \mathcal{H}' = \mathcal{F}_{k\neq 0} \), with obvious notations for the Fock spaces associated to the zero mode and the remaining modes. Consider the weight

\[
W_{\mu,\Lambda}(z) := \Xi_\Lambda(\beta, \mu, \lambda)^{-1} \text{Tr}_{\mathcal{H}'} \langle z | \exp(-\beta H_{\Lambda,\mu,\lambda}) | z \rangle .
\]

For almost all \( \lambda > 0 \) it was proved in [SY07] that the density of distribution \( W_{\mu,\Lambda}(\zeta \sqrt{V}) \) converges, as \( V \to \infty \), to a \( \delta \) function at the point \( \zeta_{\text{max}}(\lambda) = \lim_{V \to \infty} z_{\text{max}}(\lambda)/\sqrt{V} \), where \( z_{\text{max}}(\lambda) \) maximizes the partition function \( \text{Tr}_{\mathcal{H}'} \exp(-\beta (H_{\Lambda,\mu,\lambda})'(z)) \). Although [SY07] took \( \phi = 0 \) in (1.8), their results in the general case (1.8) may be obtained by the trivial substitution \( b_0 \to b_0 \exp(-i\phi) \), \( b_0^\dagger \to b_0^\dagger \exp(i\phi) \) coming from (1.6). Note that their expression (34) in [SY07] may be thus re-written as

\[
\lim_{V \to \infty} \omega_{\beta,\mu,\Lambda,\lambda}(\eta_\Lambda(b_0^\dagger \exp(i\phi))) = \lim_{V \to \infty} \omega_{\beta,\mu,\Lambda,\lambda}(\eta_\Lambda(b_0 \exp(-i\phi)))
\]

\[
= \zeta_{\text{max}}(\lambda) = \frac{\partial p(\mu, \lambda)}{\partial \lambda},
\]

and consequently

\[
\lim_{V \to \infty} \omega_{\beta,\mu,\Lambda,\lambda}(\eta_\Lambda(b_0^\dagger)\eta_\Lambda(b_0)) = |\zeta_{\text{max}}(\lambda)|^2.
\]

Here above,

\[
p(\beta, \mu, \lambda) = \lim_{V \to \infty} p_{\beta,\mu,\Lambda,\lambda} ,
\]

is the pressure in the thermodynamic limit. Equality (4.37) follows from the convexity of \( p_{\beta,\mu,\Lambda,\lambda} \) in \( \lambda \) by the Griffiths lemma [Gri66]. As it is shown in [SY07] the pressure \( p(\beta, \mu, \lambda) \) is equal to

\[
p(\beta, \mu, \lambda)' = \lim_{V \to \infty} p_{\beta,\mu,\Lambda,\lambda}'.
\]

As well as it is also equal to the pressure \( p(\beta, \mu, \lambda)'' \), which is the thermodynamic limit of the pressure associated to the upper symbol of \( H_{\Lambda,\mu,\lambda} \).

It is crucial in the proof of [SY07] that all of these three pressures coincide with \( p_{\text{max}}(\beta, \mu, \lambda) \), which is the pressure associated to \( \text{max} \langle z | \exp(-\beta H_{\Lambda,\mu,\lambda})'(z) \rangle \).

**Theorem 4.4.** Consider the system of interacting Bosons (4.5)-(4.8). If the system displays ODLRO in the sense of (4.25), the limit \( \omega_{\beta,\mu,\phi} := \lim_{\lambda \to +0} \lim_{V \to \infty} \omega_{\beta,\mu,\Lambda,\lambda,\phi} \), on the set \( \{ \eta(b_0^\dagger)^m \eta(b_0)^n \}_{m,n=0,1} \) exists and satisfies

\[
\omega_{\beta,\mu,\phi}(\eta(b_0^\dagger)) = \sqrt{\rho_0} \exp(i\phi) ,
\]

\[
\omega_{\beta,\mu,\phi}(\eta(b_0)) = \sqrt{\rho_0} \exp(-i\phi) ,
\]

18
together with
\[ \omega_{\beta,\mu,\phi}(\eta(b_0^*)\eta(b_0)) = \omega_{\beta,\mu}(\eta(b_0^*)\eta(b_0)) = \rho_0 \quad \forall \phi \in [0, 2\pi) , \] (4.43)

and
\[ \omega_{\beta,\mu} = \frac{1}{2\pi} \int_{0}^{2\pi} d\phi \, \omega_{\beta,\mu,\phi} . \] (4.44)

On the Weyl algebra the limit defining \( \omega_{\beta,\mu,\phi} \), \( \phi \in [0, 2\pi) \) exists along a net in the \((\lambda, V)\) variables, and defines ergodic states coinciding with those states that explicitly constructed in Theorem 6.1. Conversely, if SSB occurs in the special sense that (4.41) and (4.42) hold, with \( \rho_0 \neq 0 \), then ODLRO in the sense of (4.25) takes place.

**Proof.** We need only prove the direct statement, because the converse follows by applying the Schwarz inequality to the states \( \omega_{\beta,\mu,\phi} \), together with the forthcoming (4.51).

We thus prove ODLRO \( \Rightarrow \) SSB. We first assume that some state \( \omega_{\beta,\mu,\phi_0}, \phi_0 \in [0, 2\pi) \) satisfies ODLRO. Then by (4.38),
\[ \lim_{\lambda \to +0} \lim_{V \to \infty} \omega_{\beta,\mu,\lambda}(\eta(b_0^*)\eta(b_0)) = \lim_{\lambda \to +0} |\zeta_{\text{max}}(\lambda)|^2 =: \rho_0 > 0 . \] (4.45)

The above limit exists by the convexity of \( p(\mu, \lambda) \) in \( \lambda \) and (4.20) by virtue of (4.45),
\[ \lim_{\lambda \to +0} \frac{\partial p(\mu, \lambda)}{\partial \lambda} \neq 0 . \] (4.46)

At the same time, (4.37) shows that all states \( \omega_{\beta,\mu,\phi} \) satisfy (4.45). Thus, SSB is broken in the states \( \omega_{\beta,\mu,\phi}, \phi \in [0, 2\pi) \). We now prove that the original assumption (4.25) implies that all states \( \omega_{\beta,\mu,\phi}, \phi \in [0, 2\pi) \) exhibit ODLRO.

Gauge invariance of \( \omega_{\beta,\mu,\Lambda} \) (or equivalently \( H_{\Lambda,\mu} \)) yields, by (4.7), (4.26),
\[ \omega_{\beta,\mu,\Lambda}(\eta(b_0^*)\eta(b_0)) = \omega_{\beta,\mu,\Lambda,-\lambda}(\eta(b_0^*)\eta(b_0)) . \] (4.47)

Again by (4.7), (4.17) and gauge invariance of \( H_{\Lambda,\mu} \),
\[ \lim_{\lambda \to -0} \frac{\partial p(\mu, \lambda)}{\partial \lambda} = - \lim_{\lambda \to +0} \frac{\partial p(\mu, \lambda)}{\partial \lambda} , \]
and, since by convexity the derivative \( \partial p(\mu, \lambda)/\partial \lambda \) is monotone increasing, we find
\[ \lim_{\lambda \to +0} \frac{\partial p(\mu, \lambda)}{\partial \lambda} = \lim_{\lambda \to +0} \zeta_{\text{max}}(\lambda) = \sqrt{\rho_0} , \] (4.48)
\[ \lim_{\lambda \to -0} \frac{\partial p(\mu, \lambda)}{\partial \lambda} = - \lim_{\lambda \to +0} \zeta_{\text{max}}(\lambda) = -\sqrt{\rho_0} . \] (4.49)

Again by (4.47),
\[ \lim_{\lambda \to -0} \lim_{V \to \infty} \omega_{\beta,\mu,\Lambda}(\eta(b_0^*\eta(b_0)) = \lim_{\lambda \to +0} \lim_{V \to \infty} \omega_{\beta,\mu,\Lambda}(\eta(b_0^*\eta(b_0)) . \] (4.50)
By [SY07], the weight $W_{\mu,\lambda}$ is, for $\lambda = 0$, supported on a disc with radius equal to the right-derivative (4.46). Convexity of the pressure as a function of $\lambda$ implies

$$\frac{\partial p(\mu, \lambda)}{\partial \lambda} - 0 \leq \lim_{\lambda \to +0} \frac{\partial p(\mu, \lambda)}{\partial \lambda} \leq \lim_{\lambda \to -0} \frac{\partial p(\mu, \lambda)}{\partial \lambda} \leq \frac{\partial p(\mu, \lambda)}{\partial \lambda} + 0,$$

for any $\lambda^- < 0 < \lambda^+$. Therefore, by the Griffiths lemma (see e.g. [Gri66], [SY07]) one gets

$$\lim_{\lambda \to -0} \lim_{V \to \infty} \omega_{\beta,\mu,\Lambda,\lambda}(\eta(b_0^*)\eta(b_0)) \leq \lim_{V \to \infty} \omega_{\beta,\mu,\Lambda,\lambda}(\frac{b_0^*b_0}{V}) \leq \lim_{\lambda \to +0} \lim_{V \to \infty} \omega_{\beta,\mu,\Lambda,\lambda}(\eta(b_0^*)\eta(b_0)) .$$

Then (4.50) and (4.51) yield

$$\lim_{V \to \infty} \omega_{\beta,\mu,\Lambda}(\frac{b_0^*b_0}{V}) = \lim_{\lambda \to +0} \lim_{V \to \infty} \omega_{\beta,\mu,\Lambda,\lambda}(\eta(b_0^*)\eta(b_0)) \forall \phi \in [0, 2\pi) .$$

This proves that all $\omega_{\beta,\mu,\phi, \phi} \in [0, 2\pi)$ satisfy ODLRO, as asserted.

By (4.37) and (4.48) one gets (4.41) and (4.42). Then (4.44) is a consequence of the gauge-invariance of $\omega_{\beta,\mu}$. Ergodicity of the states $\omega_{\beta,\mu,\phi, \phi} \in [0, 2\pi)$ follows from (4.52) and (4.41), (4.42).

An equivalent construction is possible using the Weyl algebra instead of the polynomial algebra, see [Ver11], pg. 56 and references given there for theorem 6.1 and similarly we could have proceeded so here. The limit along a subnet in the $(\lambda, V)$ variables exists by weak* compactness, and, by asymptotically abelianness of the Weyl algebra for space translations (see, e.g., [BR97], Example 5.2.19), the ergodic decomposition (4.44), which is also a central decomposition, is unique. Thus, the $\omega_{\beta,\mu,\phi, \phi} \in [0, 2\pi)$ coincide with the states constructed in Theorem 6.1.

**Remark 4.5.** Our Remark 4.3 and Theorem 4.4 elucidate a problem discussed in [SY07]. In this paper the authors defined a generalised Gauge Symmetry Breaking via quasi-average (GSB)$_{Q}$, i.e. by $\lim_{\lambda \to +0} \lim_{V \to \infty} \omega_{\beta,\mu,\Lambda,\lambda}(\eta(b_0)) \neq 0$. (If it involves other than gauge group, we denote this by (SSB)$_{Q}$.) Similarly they modified definition of the one-mode condensation denoted by (BEC)$_{Q}$, and, established the equivalence: (GSB)$_{Q} \Leftrightarrow$ (BEC)$_{Q}$. They asked whether (BEC)$_{Q} \Leftrightarrow$ BEC? We show that (GSB)$_{Q}$ coincides with GSB (Definition 2.2), and that BEC is indeed equivalent to (BEC)$_{Q}$.

**Remark 4.6.** The states $\omega_{\beta,\mu,\phi}$ in Theorem 4.4 have the property ii) of Theorem 6.1 i.e., if $\phi_1 \neq \phi_2$, then $\omega_{\beta,\mu,\phi_1} \neq \omega_{\beta,\mu,\phi_2}$. By a theorem of Kadison [Kad62], two factor states are either disjoint or quasi-equivalent (see Remark 3.1 and references given there), and thus the states $\omega_{\beta,\mu,\phi}$ for different $\phi$ are mutually disjoint. This fact has a simple explanation: only for a finite system is the Bogoliubov transformation (4.10) (which also applies to the interacting system), which connects different $\phi$, unitary: for infinite systems one has to make an infinite change of an extensive observable $b_0\sqrt{V}$, and mutually disjoint sectors result. This phenomenon also occurs with regard to the magnetization in quantum spin systems, in correspondence to (2.30) and it is in this sense that the word ”degeneracy” must be understood (compare with the discussion in [Bog70]).
5 Concluding remarks

In this paper, we reexamined the issue of ODLRO versus SSB by the method of Bogoliubov quasi-averages, commonly regarded as a symmetry-breaking trick. We showed that it represents a general method of construction of extremal, pure or ergodic states, both for quantum spin systems (Proposition 3.1) and many-body Boson systems (Theorem 4.4). The breaking of gauge symmetry in the latter has some analogy with the breaking of gauge and $\gamma_5$ invariance in the Schwinger model (quantum electrodynamics of massless electrons in two dimensions) ([LS71]), in which the vacuum state decomposes in a manner similar to (4.44). We believe, and argued so in Section 3, that the quasi-average method is the only universally applicable method, in particular to relativistic quantum field theory, to which the imposition of classical boundary conditions is bound to be inconsistent with the general principles of local quantum theory, as in the case of the Casimir effect [KNW07].

A general necessary feature for the applicability of the Bogoliubov method is the existence of an order parameter. In the two examples treated, the Heisenberg ferromagnet (Section 2, see also remark 2.5 concerning order parameters for quantum spin systems in the general case) and many-body Boson systems (Section 4), the respective symmetry-breaking fields (3.3) and (4.7) are qualitatively different. Note that (3.3) commutes with $H_\Lambda$ and the corresponding order parameter, the magnetization, is physically measurable. Whereas (4.7) does not commute with $H_\Lambda - \mu N_\Lambda$ (even in the free-gas case!), and the order parameter involves a phase by (4.41), (4.42), which, at first glance, is not physically measurable. It has been observed, however, in the interference of two condensates of different phases [KK97], [BZ], in the case of trapped gases. In the latter case, Condensation takes place at $k \neq 0$, and the version of Theorem 4.4 due to Pulè et al [VZ05] is the relevant one. Finally, in the quantum spin case there is a residual symmetry (Remark 2.4, but none, of course, in the Boson case. These remarks exemplify the rather wide diversity of types of the Bogoliubov quasi-average, which make its conjectured universal applicability further plausible, see e.g. random boson systems [JaZ10].

As remarked by Swieca [Swi70], it is the fluctuations occurring all over space which do not allow to take the "charge" (e.g. (2.26)) in the limit $V \to \infty$ as a well-defined operator (this would, in particular, contradict (2.23)), even if a meaning has been given to the density - as in (2.21) - see also Remark 2.6. The additional input we offer is that the fluctuation of the charge density (or of a related operator) is precisely a very nontrivial condition of ODLRO (2.32) or (4.23) respectively.

As a final question, the treatment of the free Bose gas suggests that the chemical potential $\mu(\lambda) < 0$ for $\lambda \neq 0$ even after the thermodynamic limit also for interacting systems. It should be interesting to look at Bose gases with repulsive interactions [BR80] from the point of view of quasi-average: (SSB)$_{qa}$, using the symmetry breaking term (4.7).

6 Appendix A

In this Appendix we reproduce, for the reader’s convenience, the statement of the basic theorem of Fannes, Pulè and Verbeure [PV82], see also [VZ05] for the extension to nonzero momentum, and Verbeure’s book [Ver11]. Unfortunately, neither [PV82] nor [VZ05] show
that the states $\omega_{\beta,\mu,\phi} \in [0, 2\pi)$ in the theorem below are ergodic. The simple, but instructive proof of this fact was given by Verbeure in his book [Ver11].

**Theorem 6.1.** Let $\omega_{\beta,\mu}$ be an analytic, gauge-invariant equilibrium state. If $\omega_{\beta,\mu}$ exhibits ODLRO (4.25), then there exist ergodic states $\omega_{\beta,\mu,\phi} \in [0, 2\pi)$, not gauge invariant, satisfying (i) $\forall \theta, \phi \in [0, 2\pi)$ such that $\theta \neq \phi$, $\omega_{\beta,\mu,\phi} \neq \omega_{\beta,\mu,\theta}$; (ii) the state $\omega_{\beta,\mu}$ has the decomposition

$$\omega_{\beta,\mu} = \frac{1}{2\pi} \int_0^{2\pi} d\phi \omega_{\beta,\mu,\phi}.$$ 

(iii) For each polynomial $Q$ in the operators $\eta(b_0)\eta(b_0^*)$, and for each $\phi \in [0, 2\pi)$,

$$\omega_{\beta,\mu,\phi}(Q(\eta(b_0^*), \eta(b_0))X) = \omega_{\beta,\mu,\phi}(Q(\sqrt{\rho_0}\exp(-i\phi), \sqrt{\rho_0}\exp(i\phi))X) \quad \forall X \in \mathcal{A}.$$ 

We remark, with Verbeure [Ver11], that the proof of Theorem A.1 is constructive. One essential ingredient is the separating character (or faithfulness) of the state $\omega_{\beta,\mu}$, i.e., $\omega_{\beta,\mu}(A) = 0$ implies $A = 0$. This property, which depends on the extension of $\omega_{\beta,\mu}$ to the von-Neumann algebra $\pi_{\omega}(\mathcal{A})''$ (see [BR97], [Hug72]) is true for thermal states, but is not true for ground states, even without this extension: in fact, a ground state (or vacuum) is non-faithful on $\mathcal{A}$ (see proposition 3 of [Wre05]). We see, therefore, that thermal states and ground states might differ with regard to the ergodic decomposition (ii). Compare also with our discussion in the Concluding remarks.

**Acknowledgements**

Some of the issues dealt with in this paper originate in the open problem posed in Sec.3 of [SW09] and at the of [JaZ10]. One of us (W.F.W.) would like to thank G. L. Sewell for sharing with him his views on ODLRO along several years. He would also like to thank the organisers of the Satellite conference ”Operator Algebras and Quantum Physics” of the XVIII conference of the IAMP (Santiago de Chile) in São Paulo, July 17th-23rd 2015, for the opportunity to present a talk in which some of the ideas of the present paper were discussed. We are thankful to Bruno Nachtergaele for very useful remarks, suggestions, and corrections, which greatly improved and clarified the paper.
