(Received 18 December 2013; accepted 13 March 2014; published online 26 March 2014)

We report the development of superconducting tantalum nitride (TaN_x) normal metal-insulator-superconductor (NIS) tunnel junctions. For the insulating barrier, we used both AlO_x and TaO_x (Cu-AlO_x-Al-TaN_x and Cu-TaO_x-TaN_x), with both devices exhibiting temperature dependent current-voltage characteristics which follow the simple one-particle tunneling model. The superconducting gap follows a BCS type temperature dependence, rendering these devices suitable for sensitive thermometry and bolometry from the superconducting transition temperature T_C of the TaN_x film at ~5 K down to ~0.5 K. Numerical simulations were also performed to predict how junction parameters should be tuned to achieve electronic cooling at temperatures above 1 K. © 2014 AIP Publishing LLC. [http://dx.doi.org/10.1063/1.4869563]

Normal metal-insulator-superconductor (NIS) tunnel junction devices aimed at low temperature thermometry, bolometry, and refrigeration have witnessed significant developments in the last decade. Aluminum (Al) based NIS devices already offer sensitive thermometry in the sub 1 K range, and significant cooling power approaching 1 nW at ~0.3 K has recently been demonstrated. In addition to direct electronic cooling, sizeable indirect phonon cooling of suspended membranes, beams, and a general-purpose refrigeration platform have been achieved using Al coolers. However, to achieve operation at higher temperatures, one must switch to materials with higher superconducting transition temperatures (T_C) than the T_C of Al at ~1.2 K, as T_C limits the maximum range of thermometry, and cooling power drops strongly above T ~0.4 T_C.

Recently, we fabricated Nb (T_C ~ 8 K) and NbN_x (T_C ~ 12 K) based NIS devices and demonstrated an order of magnitude increase of the thermometry range, and an observation of some electronic cooling in the Nb device. However, as the optimal operational temperature for cooling for those type of devices is around 3.5–5 K, one should also develop NIS devices with a T_C in the intermediate range between Al and Nb/NbN devices. This is important because the cooling power also deteriorates fast when the operational temperature is lower than the optimal, and thus Nb or NbN based coolers may not be able to work effectively enough in the temperature range 1–3 K. Here, we experimentally demonstrate that tantalum nitride (TaN) with a T_C ~ 5 K can be used as the superconducting electrode in a micron-scale NIS device. The thermometric characteristics were essentially ideal in the temperature range 0.5–5 K, and the observed specific tunneling resistance and the broadening of the superconducting density of states (DOS) were reasonably low, giving us hope of also developing electronic coolers in the temperature range 1–3 K in the future. This was elaborated in numerical simulations, which demonstrated that a further lowering of the specific tunneling resistance of the junctions (in principle a straightforward process) would lead to a sizeable electronic cooling at temperatures around 1.5–3 K, despite the observed broadening of the superconducting density of states being higher than for typical Al junctions. In addition, if the broadening could be reduced to levels commonly seen for Al, a truly wonderful device capable of reducing temperature from 1.2 K to 0.2 K would follow.

Tantalum nitride (TaN_x) is a material whose T_C has been shown to be tunable in thin films between 4 and 10.8 K by adjusting the growth parameters. Moreover, depending upon the amount of incorporated nitrogen x, TaN_x can be a superconductor, insulator, or a metal at low temperatures. In superconducting device applications, however, TaN has not been used widely. In its normal state, it has been used as a barrier material in superconductor-normal metal-superconductor (SNS) Josephson junctions with NbN (Refs. 18–20) and NbTiN (Ref. 21) as the superconducting electrode materials. As a superconductor, the only device application so far has been for superconducting single photon detection, and notably, no tunnel junction devices have been reported before. Recently, we were able to grow high quality TaN_x thin films with T_C up to ~8 K using a pulsed laser deposition (PLD) technique. Furthermore, we have already fabricated NbN_x based NIS junctions, using PLD for the growth of NbN_x films, and electron beam lithography (EBL), reactive ion etching (RIE), and shadow angle evaporation for the device fabrication, with an ex-situ thermally oxidized Al barrier. These two advances were combined here to develop Cu-AlO_x-Al-TaN_x NIS tunnel junctions.

First, 30 nm thick superconducting TaN_x films with T_C in the range ~4–5 K were deposited on (100) oriented MgO single crystals using a PLD technique described in detail elsewhere. A typical temperature dependence of the resistance of such a bare TaN_x film is shown in Figure 1(a). MgO was chosen as the substrate because the films grown on it were shown to be monophase superconducting FCC (rocksalt), while in the films grown on oxidized silicon a coexisting non-superconducting hexagonal phase was also found. The TaN_x films were patterned into 1 μm wide electrodes and large contact pads by EBL and RIE. To make a more

---

*Electronic mail: maasilta@jyu.fi*
resistant etch mask, the TaN$_x$ was first covered with a 50 nm thick evaporated Cu film, on top of which a 400 nm thick positive PMMA resist was spun, followed by EBL electrode patterning and removal of the Cu in the exposed regions with a chemical etch (30% H$_2$O$_2$, glacial acetic acid, DI water 1:1:18). After that, the exposed TaN$_x$ was etched by RIE using CHF$_3$, 50 sccm and O$_2$, 5 sccm at a power 100 W and pressure 55 mTorr, the PMMA removed, and finally the remaining Cu removed by another chemical etch step.

The electrode patterning was followed by the fabrication of three distinct types of devices using a second overlay EBL step and ultra-high vacuum (UHV) e-beam evaporation. For the first device type, a 40 nm thick, 0.5 μm wide, and 15 μm long aluminum cross strip was deposited across the electrodes, without any explicit attempt to form tunnel barriers. The purpose of this sample is to determine the quality of the Al-TaN$_x$ contact, as an unwanted native oxide barrier may exist on the surface of the TaN$_x$ film. For the second device type, the method previously developed for the NbN$_x$ NIS junction fabrication with AlO$_x$ tunnel barriers has been used. First, 40 nm thick Al islands of size 6 μm × 6 μm were evaporated on top the TaN$_x$ electrodes, followed by in-situ oxidation at room temperature in 50 millibars of O$_2$ for 4 min, to grow the AlO$_x$ tunnel barriers. Then, without breaking the vacuum, a 100 nm thick Cu strip of width 0.5 μm was evaporated to form the connection between two TaN$_x$ electrodes (separated by a distance of 15 μm) so that a series connection of two Cu-AlO$_x$-Al-TaN$_x$ NIS tunnel junctions (SINIS) is formed [Fig. 1(b)]. The third device type was identical with the second, except that no Al was deposited, and the TaN$_x$ electrodes were directly oxidized in 400 millibars of O$_2$ for 30 min. The goal of this process is a SINIS device with a Cu-TaO$_x$-TaN$_x$ tunnel junction structure. The typical junction dimensions were ~1 × 0.5 μm$^2$.

Since the TaN$_x$ films come in contact with ambient atmosphere for prolonged periods of time during the process of fabrication, we investigated the effects of a possible native oxide barrier with the help of the first type of TaN$_x$-Al-TaN$_x$-Al-AlO$_x$-Cu device. The measured voltage and differential resistance vs. current characteristics at 4.2 K are shown in Figure 1(c). Clearly, the data shows that the contact resistance is low (<1Ω/junction (four orders of magnitude less than the tunneling resistances of the second and third type devices, as will be shown later), and that the general behavior is that of a good NS contact, although several resonance features are seen, possibly originating from multiple Andreev reflections. However, the NS contact resistance in NbN devices was actually orders of magnitude higher for unknown reasons.

The current-voltage and conductance-voltage measurements for the second and third type devices were carried out using a He$^−$-He$^3$ dilution refrigerator. The measurement lines had three stages of filtering: pi-filters at 4.2 K, RC-filters at the base temperature, and microwave filtering between these two (Thermocoax cables of length 1.5 m). For the measurement of conductance, a lock-in technique with a 0.04 mV excitation voltage and 17 Hz frequency was used. In Figure 2, the current-voltage (I-V) characteristics at various bath temperatures $T_{Bath}$ for a TaN$_x$-Al-AlO$_x$-Cu based double junction SINIS device are shown in (a) log-linear and (b) linear scales, respectively, together with the corresponding theoretical fits based on the single-particle tunneling model $\frac{2\pi}{h} \int_{0}^{\frac{1}{2}eV} dN_S(e)(f_S(e - eV) - f_S(e + eV))$, where $f_S(e)$ is the Fermi function in Cu wire, and $N_S(e)$ is the normalized broadened superconducting quasiparticle DOS in the Dynes

![Image](image-url)
From the fits, we also get the temperature dependence of the superconducting gap $\Delta$, which was seen to follow the simple BCS theory well, in contrast to the NbN$_x$ based devices which exhibited stronger modifications due to proximity effect. At 0.18 K, the measured $\Delta$ was $\sim$0.9 meV, about four times higher than a typical Al film gap, indicating that the Al layer is well proximized by the TaN$_x$. This value of $\Delta$ is almost the same as in the NbN NIS devices although $T_C = 5$ K is less than half, an observation which is consistent with the fact that the contact resistance between TaN$_x$ and Al is much lower. All the theory fits to the $I - V$ and conductance curves were obtained with a broadening parameter $\Gamma/\Delta(0) = 7 \times 10^{-2}$, i.e., a value which is slightly higher than the smallest value observed in the NbN$_x$ devices, $\Gamma_{\text{NbN}}/\Delta_{\text{NbN}} = 2.4 \times 10^{-2}$. Similar to the NbN case, strong coupling theory did not fit the data well (not shown). Finally, the total $R_T$ of this device was, surprisingly, found to evolve with temperature, from $\sim$31 k at 5 K to $\sim$26.5 k at 3.8 K and $\sim$24.5 k at still lower temperatures. This translates to a specific junction resistance $r_S$ of $\sim$6.5 k$\Omega$ $\mu$m$^2$, which is about two orders of magnitude smaller than that in the NbN$_x$ devices fabricated in a similar manner, but still about three-ten times higher than that of typical high power Cu-AlO$_x$-Al tunnel junction coolers.

For the devices of the third type (TaN$_x$-TaO$_x$-Cu), the yield was quite low—most of them were shorts. However, some were tunnel junctions. In Figures 3(a) and 3(b), the current-voltage ($I-V$) characteristics at various $T_{\text{Bath}}$ of such a TaN$_x$-TaO$_x$-Cu single NIS junction are shown in (a) log-linear and (b) linear scale, respectively, together with the corresponding theoretical fits. The measured and theoretical conductance curves are shown in Figure 3(c). From the theoretical fits, the obtained value of $\Gamma/\Delta(0)$ and $\Delta(0)$ were 0.13 and 0.87 meV, respectively, with $T_C = 4.5$ K being the measured value of the TaN$_x$ film. Here, the obtained value of $R_T$ evolved with temperature even more strongly, from $\sim$24 k at 5 K to $\sim$16.5 k$\Omega$ below 5 K. The origin of this temperature dependence of $R_T$ is unclear to us at the moment. The largest change seems to be correlated with the transition to the superconducting state, but some temperature dependence seems to be left even at temperatures much below $T_C$. Although the $\Delta$ values of TaN$_x$-TaO$_x$-Cu and TaN$_x$-Al-AlO$_x$-Cu junctions are almost identical, the low yield and the larger value of $\Gamma$ of the latter render them unfit for real device applications.

Figure 4 shows the thermometric response in the usual measurement configuration where the NIS junction device is current biased, and its voltage ($V$) response is measured as a function of $T_{\text{Bath}}$. Of the (a) double junction TaN$_x$-Al-AlO$_x$-Cu device and (b) single junction TaN$_x$-TaO$_x$-Cu device. For both devices, the measured temperature sensitivity was $\sim$0.14 mV/K/junction from $T_C$ down to $\sim$0.5 K, as expected from theory, but at the lowest temperatures there is a saturation and even a curious downturn of the voltage. This downturn cannot be explained by any theory where $R_T$ is temperature independent for such low bias (sub-gap) values, and thus the thermometry data confirms the picture of changing $R_T$, as can be seen from the representative theory curves.

Having obtained the values for $\Gamma$ and $r_S$ for the TaN$_x$ NIS devices, we should compare them with previous results using other superconductors. In Table I, we have compiled...
photon-assisted tunneling. According to that picture NbN junctions do not seem as promising for cooling as TaN, due to the much larger value of the broadening parameter compared to the results by other labs. However, if extreme conditions are achieved, solid purple line, which suggests that the broadening in our higher gap junctions is due to some other mechanism.

Finally, to answer better whether TaN based NIS junction technology is comparable to the earlier results for Nb-Al-AlO$_2$-Cu junctions, explained by electron-phonon coupling constant. A typical value for the electron-phonon limited heat transport and Cu as normal metal. Only regions where net cooling occur ($T_{\text{Bath}} > T_S$) are shown. (a) Cooling as a function of $T_{\text{Bath}}$ and $\Gamma/\Delta(0)$ for $r_S = 6.5$ kΩ µm$^2$. In (b) and (c), calculated cooling as a function of $T_{\text{Bath}}$ and $\Gamma/\Delta(0)$ for $r_S = 6.5$ kΩ µm$^2$. In (b), $\Gamma/\Delta(0)$ is fixed at the observed values for $10^2$, a fair amount of cooling (up to 0.3 K) at high $T_{\text{Bath}}$ is possible when $r_S < 10$ kΩ µm$^2$. Even this would far fall short from the ultimate goal to cool the metal island from 1.2 K to 0.3 K. In order to achieve such a large magnitude in cooling, a concomitant reduction in $\Gamma/\Delta(0)$ of these TaN$_x$ devices is also necessary. As shown if Fig. 5(c), if $\Gamma/\Delta(0)$ could be lowered to $10^{-4}$ (typical for Al devices), then for $r_S < 100$ kΩ µm$^2$ such a large cooling would be theoretically possible. Interestingly, these kind of values for $\Gamma$ and $r_S$ have been obtained experimentally for Al-AlO$_2$-Cu junctions.

In conclusion, we have demonstrated the application potential of normal metal-insulator-superconductor tunnel junction devices with TaN as the superconductor. The electrical characteristics of these devices follow the simple one-particle tunneling model, and the superconducting gap exhibits a BCS type temperature dependence. We also demonstrated sensitive thermometry between 0.5 and 5 K, where the lower limit was shown to be caused by an unexpected

30 nm, with a lateral size the same as the total junction area $A$. Electron-phonon interaction limited heat flow out of the island was also assumed, which is the typical situation for junctions on bulk substrates leading to heat balance $P_{\text{cool}} = \sum \Omega (T_{\text{Bath}}^3 - T_S^3)$, where $P_{\text{cool}}$ is the cooling power of the junctions that can be calculated when junction parameters are known. The normal metal volume, and $\Sigma$ is the electron-phonon coupling constant. A typical value for $\Sigma = 2 \times 10^3$ W/(m$^2$K$^3$) in Cu was used. Since $P_{\text{cool}} \propto A$ and $\Omega \propto A$, the results shown here are independent of $A$, and therefore we use the specific junction resistance $r_S$ as parameter. In Figure 5(a), we show the expected decrease of $T_N$ below $T_{\text{Bath}}$, as a function of $\Gamma$ and $T_{\text{Bath}}$, for the value of specific junction resistance observed in the experiment $r_S = 6.5$ kΩ µm$^2$. We find that a bit of cooling is expected at low $T_{\text{Bath}}$, $0.2-0.3$ K if $\Gamma/\Delta(0)$ could be lowered to values $<10^{-3}$. However, at that temperature range Al coolers perform better. On the other hand, if the value of $r_S$ is lowered, as shown in Fig. 5(b), $T_{\text{Bath}}(\Gamma)$ is fixed at the observed value $7 \times 10^{-2}$, a fair amount of cooling (up to 0.3 K) at high $T_{\text{Bath}}$ is possible when $r_S < 10$ kΩ µm$^2$. Even this would far fall short from the ultimate goal to cool the metal island from 1.2 K to 0.3 K. In order to achieve such a large magnitude in cooling, a concomitant reduction in $\Gamma/\Delta(0)$ of these TaN$_x$ devices is also necessary. As shown if Fig. 5(c), if $\Gamma/\Delta(0)$ could be lowered to $10^{-4}$ (typical for Al devices), then for $r_S < 100$ kΩ µm$^2$ such a large cooling would be theoretically possible. Interestingly, these kind of values for $\Gamma$ and $r_S$ have been obtained experimentally for Al-AlO$_2$-Cu junctions.

temperature variability of the tunneling resistance. The measured effective broadening of the superconducting density of states and the specific tunneling resistance of these devices were just high enough to inhibit any electronic cooling. However, as we showed theoretically, a realistic reduction of these parameters for TaN devices would lead to a dramatic breakthrough in the development of practical electronic coolers for 1 K temperature range. Future efforts need to be especially focused on understanding the broadening of the superconducting density of states and how to reduce it.

This research has been supported by Academy of Finland Project No. 260880. We thank A. Torgovkin for help with low temperature measurements.
