IncRNA WT1-AS inhibits the aggressiveness of cervical cancer cell via regulating p53 expression via sponging miR-330-5p

Background: Emerging evidences have demonstrated that IncRNAs play vital roles in various pathological processes, including cancer. The IncRNA WT1 antisense RNA (WT1-AS) serves as a tumor suppressor in various cancers. Nevertheless, the expression and precise function of WT1-AS in cervical carcinoma still remain not yet investigated. The objective of our study was to explore the expression of WT1-AS and its biological roles in cervical cancer.

Methods: Differences in the lncRNA expression profiles between cervical cancer and adjacent normal tissues were assessed by lncRNA expression microarray analysis. The expression of p53 in cervical cancer cell was assessed by qRT-PCR and immunofluorescence assay. Loss-of-function studies were used to explore the effect of lncRNA WT1-AS on the growth and metastasis of cervical cancer cell in vitro and in vivo.

Results: Our results demonstrated that WT1-AS was remarkably down-regulated in cervical carcinoma. Functional assays proved that up-regulation of WT1-AS significantly suppressed cervical cancer cell proliferation, migration and invasion. In addition, the luciferase reporter assay identified that miR-330-5p was the target of WT1-AS. Moreover, tumor suppressor p53 was identified as the direct target of miR-330-5p and alternation of miR-330-5p/p53 axis reversed the effects of WT1-AS in cervical cancer cell.

Conclusion: Altogether, our findings suggested that WT1-AS was down-regulated in cervical carcinoma and WT1-AS suppressed cervical carcinoma cell proliferation, migration and invasion through regulating the miR-330-5p/p53 axis.

Keywords: cervical cancer, WT1-AS, miR-330-5p, p53, metastasis

Introduction
Cervical cancer is one of the most deadly cancers, with its incidence increased drastically worldwide.1 Once cervical cancer cell disseminates to distant and internal organs, cervical cancer will be almost resistant to the current clinical treatments and becomes an incurable disease.2 Hence, it is noteworthy that the occurrence of cancer cell metastasis facilitates cervical cancer to be an aggressive and life-threatening disease, and the identification of metastasis-related biomarkers and therapeutic targets is urgent for the treatment of cervical cancer. Recently, accumulating evidence suggest that IncRNAs act as important modulators in the tumorigenesis and progression of cervical carcinoma and may become innovative treatment targets.3 Currently, evidence demonstrate that IncRNAs have crucial actions in various cellular processes, including cancer cell growth, epithelial–mesenchymal transition (EMT), and metastasis.4 Studies reveal that IncRNAs are commonly dysexpressed in multiple types of cancer.
Few studies prove that lncRNAs mediate genes expression at transcriptional level, posttranscriptional level, or epigenetic level. In addition, extensive lncRNAs act via ceRNA for miRNA targets, thereby preventing miRNAs from binding to their target genes.6

FENDRR, which locates at chr3q13.31, consists of four exons and has a length of 3,099 nucleotides.7 A previous study identifies that the low level of FENDRR is related to the poor prognosis of patients with gastric carcinoma and overregulation of FENDRR suppresses the migration and invasion capacities of gastric carcinoma cell via downregulating the expression of matrix metalloproteinase 2/9 and fibronectin1.8 In addition, FENDRR suppresses breast cancer cell growth, promotes cell apoptosis, and is closely related to the prognosis of patients with breast cancer.9 In prostate cancer, the level of FENDRR is remarkably decreased when compared to normal control, and the downregulation of FENDRR is related to the poor prognosis of patients.10 The expression of lncRNA HOTAIR is elevated in a variety of tumors and are closely associated with poor survival and high recurrence rates of tumor.11–13 Downregulation of HOTAIR suppresses cancer cell proliferation and inhibits cell metastasis. Similarly, more lncRNAs are being identified and many are need to thoroughly functionally investigated in cancers.14 WT1 antisense RNA (WT1-AS) is one of the antisense transcripts of the Wilm’s tumor gene, which encodes a zinc finger transcription domain.15 Recently, WT1-AS has proved to be aberrantly dysexpressed in several tumors, including ovarian clear cell adenocarcinoma (OCCA).16–18 The level of WT1-AS is decreased in gastric cancer tissue compared with the non-tumor tissue. The growth, migration, and invasion of gastric cancer cell are inhibited when WT1-AS was upregulated in gastric cancer cell.19 Furthermore, the promoter of WT1-AS has been proved to be markedly methylated in OCCA when compared with the serous adenocarcinoma, which suggest the potential role of WT1-AS in prognosis.16 However, the potential roles of lncRNA WT1-AS in cervical cancer invasion and metastasis have not yet been fully investigated.

In this study, we found that WT1-AS was markedly downregulated in cervical cancer, including clinical tissue and cell line. With overregulation of WT1-AS, cell growth and invasion were significantly inhibited and tumor growth was inhibited. Furthermore, we demonstrated that overregulation of WT1-AS significantly decreased the level of miR-330-5p in cervical carcinoma cell. Bioinformatics analysis and the luciferase reporter assays identified that miR-330-5p bound to WT1-AS in a sequence-specific manner. In mechanism, miR-330-5p targeted directly the mRNA of p53 in cervical cancer cell. The viral oncoprotein E6 is an essential factor for cervical cancer induced by “high-risk” mucosal HPV. Among other oncogenic activities, E6 recruits the ubiquitin ligase E6AP to promote the ubiquitination and subsequent proteasomal degradation of p53.20 As expected, we found that overregulation of miR-330-5p increased the expression of HPV E6 in cervical cancer cell, indicating that miR-330-5p inhibited the expression of p53 and was partly associated with it, regulating the level of HPV E6. Finally, we identified that WT1-AS inhibited cervical cancer cell progression and regulated p53 expression via sponging miR-330-5p. Altogether, we demonstrated that WT1-AS/miR-330-5p/p53 axis regulated the growth, migration, and invasion of cervical cancer cell, which might function as a potential target for cervical cancer treatment.

Materials and methods

Cervical cancer tissues and cell culture

The frozen human cervical cancer tissues and paratumor tissues were obtained from First People’s Hospital of Jiaozuo City. These obtained tissue specimens were utilized to generate tissue section slides and tissue microarrays for research purposes. The cervical carcinoma cells (SiHa, C-4-I, C-33-A, and Ca-Ski) and the normal cervical epithelial cell line, ECT1/E6E7, were obtained from the GuangZhou Jennio Biotech Co., Ltd (GuangZhou, GuangDong, China). Cancer cells were cultured in RPMI-1640 or DMEM containing 10% FBS (Wisent, Quebec, Canada), 100 µg/mL of streptomycin, and 100 µg/mL of penicillin and maintained in an incubator with a humidified atmosphere of 95% air and 5% CO2 at 37°C. This research was approved by the Institutional Research Committee of the First People’s Hospital of Jiaozuo City, and the informed consent was obtained from all patients. The written informed consent for participation in the study was obtained from all patients before participating in this study.

Cells’ transfections

miR-330-5p mimics, miR-330-5p inhibitor, and their controls (miR-NC or miR-NC inhibitor) were purchased from Ambion (GeneCopoeia, Guangzhou, China). Lentiviral vector encoding WT1-AS cDNA (LV-WT1-AS) was constructed by Genepharma Co., Ltd (Shanghai, China). shRNA-WT1-AS was chemically synthesized by Realgene (Nanjing, Jiangsu, China). The shRNA targeting p53 was designed by Genepharma Co., Ltd. The lentiviral vector encoding p53 cDNA was constructed by Genepharma Co., Ltd, and named as LV-p53. The empty vector was control (named as LV-vector). In brief, cells were maintained around 50–60% confluence.
in 10 cm culture dishes when transfected with plasmids. Transfection of WT1-AS or miRNAs was conducted using the Lipofectamine RNAiMAX transfection reagent (Thermo Fisher Scientific, Waltham, MA, USA) according to the manufacturer's protocol. To establish stable cell lines, media were refreshed on transfected cells 4 days later with media containing puromycin (1.5 µg/mL). Transfected cells were treated with puromycin, refreshed every 3 days, for 2 weeks.

**Luciferase reporter assay**

HEK-293T cells (1×10⁵) were seeded in a six-well plate at 70%–80% confluence. The luciferase reporter vectors for the wild-type (wt) or mutant (mut) p53 3′-UTR containing miR-330-5p binding site were constructed into pMIR-REPORT luciferase system (Thermo Fisher Scientific). The vectors expressing firefly luciferase reporter fused with wt or mut p53 3′-UTR were co-transfected with miR-330-5p or miR-NC into cell. After 24 hours, cells were harvested, and the two distinct luciferase activities were measured using Dual-luciferase reporter assay according to the manufacturer's instructions (Promega Corporation, Fitchburg, WI, USA). WT1-AS containing the predicted miR-330-5p-binding site was amplified using PCR and subcloned into a pmirGLO luciferase Target Expression Vector (Promega Corporation) to form the WT1-AS wt (pmirGLO-WT1-AS-wt) vector. The mutated miR-330-5p-binding sequence was constructed that was named as pmirGLO-WT1-AS-mut vector. The HEK-293T cells were co-transfected with PrirGLO, pmirGLO-WT1-AS-wt, prirGLO-WT1-AS-mut, and miR-330-5p mimics or negative control using Lipofectamine 2000, and the relative luciferase activity was measured using the Dual-Luciferase Reporter Assay Kit (Promega Corporation) after 24 hours.

**MTT assay**

Cells (1×10⁵) were seeded in 96-well culture plates and cultured for 1, 2, 3, or 4 days. A total of 5 mg/mL MTT was added into 96-well culture plates after each day of cell growth. Then, the cells were continually incubated for 4 hours. Then, all cell supernatant was removed, dimethyl sulfoxide (DMSO) (200 µL) was added into plate, and the OD values were detected at 490 nm.

**Wound-healing analysis**

Cells (1×10⁵) were seeded into a six-well plate and cultured for 24 hours. Then, the cells were treated with 10 µg/mL Mitomycin C (BP25312; Thermo Fisher Scientific) in culture media for 2 hours to eliminate proliferation. The monolayer cells were scratched by using a 100 µL tip, and then, the cells were cultured in serum-free medium. The image of wound closure at 0 and 24 hours was recorded under a microscope. The percentage of wound closure was calculated using ImageJ. The wound healing rate = (0 hour width of scratch – 24 hour width of scratch)/0 hour width of scratch ×100%.

**Invasion assay**

In brief, the Boyden chamber inserts were precoated with 80 µL of Matrigel (1:8 dilution) and incubated at 37°C for 30 minutes allowing a gel bed to form. The inserts were then placed onto the wells of a 24-well plate and cells (1×10⁵) were seeded into the upper chamber. A total of 600 µL of medium supplemented with 10% FBS had been added into lower chamber. After 24 hours, the invaded cells were stained with crystal violet. The cells migrated to the bottom of the inserts are counted.

**Colony formation assay**

A total of 1×10³ cells were mixed with DMEM containing soft agar (Difco, Mumbai, India) to a final concentration of 0.35%. These cells were then plated in a 25 mm³ dish coated with 0.6% soft agar in DMEM. Cells were cultured for 3 weeks. The colonies were stained with crystal violet (0.1%), and the number of cell colonies was counted.

**Apoptosis analysis**

A total of 1×10⁶ cells were collected and were re-suspended in 1 mL of binding buffer (BioLegend, San Diego, CA, USA) and incubated with Annexin V (10 µL) and PI solution (5 µL) for total 15 minutes at room temperature. Then, the cells were suspended in 500 µL of binding buffer, and apoptosis was analyzed using the FACScan flow cytometer (BD Biosciences, San Jose, CA, USA).

**In situ hybridization (ISH)**

The expression of WT1-AS in cervical cancer tissues was determined using the biotin-labeled WT1-AS probe. Paraffinized cancer sections were deparaffinized with xylene and 100% ethanol. Then, the sections were incubated with biotin-labeled probe at 40°C for 18 hours. DAB substrate was selected for the colorimetric measure of WT1-AS. Finally, sections were stained with hematoxylin followed by dehydration in graded alcohols and xylene.

**Immunofluorescence**

Cells (1×10⁵) on glass coverslips were fixed by precold acetone and then rinsed with PBS. Cells were incubated with 1% BSA/PBS for avoiding nonspecific binding. Then, cells
were incubated with anti-p53 antibody (1:500; Epitomics, Burlingame, CA, USA) at 4°C for 24 hours. Next, cells were incubated with fluorescein isothiocyanate (FITC)-conjugated goat antirabbit secondary antibody (Boster Biototechnology, Wuhan, Hubei, China). Nuclei were stained with DAPI (Boster Biototechnology).

**Quantitative real-time PCR (qRT-PCR) assay**

The total RNAs were extracted using a TRIzol kit (Thermo Fisher Scientific). The level of WT1-AS was detected using the SYBR Premix EX Taq™ II kit (TaKaRa, TakaraBio, Tokyo, Japan) on ABI Prism® 7500 (ABI, Foster, CA, USA). miRNA was collected using the PureLink™ miRNA isolation kit (Thermo Fisher Scientific), and its level was determined using the TaqMan microRNA assay kit. The relative level of miRNA and IncRNA was calculated using the 2−ΔΔCT. GAPDH and U6 were the internal controls. The sequences of the primers were as follows: WT1-AS-F: GCCTCTCTGTCCTCTTCTTTGT and WT1-AS-R: GCTGTGAGTCCTGGTGCTTAG; GAPDH-F: GCTCTCTGCTCCTCCTGTTC and GAPDH-R: ACGACCAAATCCGTGTGAC; miR-330-5p-F: TCTCTGGGCCTGTGTCTTAGGC and miR-330-5p-R: GCTATCTCAGGGCTTGTTGCTTCAGTCCTCCTGGG; and U6-F: TTCGCTTCGGCAGCACAC and U6-R: AACGCTTCACGAATTTGCCTG.

**Xenograft model of tumor growth in vivo**

All animal experiments were approved by the University Committee on the Use and Care of Animals at First People’s Hospital of Jiaozuo City in accordance with Institutional Guidelines and the Guide for the Care and Use of Laboratory Animals (NIH publication no 85-23, revised 1996). A total of 100 µL of WT1-AS or its positive control (empty vector) cell suspension (3×10^6) was subcutaneously inoculated into the flank of nude mice. The tumor volume was measured each week using a caliper and calculated as the following formula: length × width^2/2.

**Experimental metastasis assay**

For experimental metastasis analysis, the nude mice were injected at the lateral tail vein with (5×10^6) SiHa cells carrying shRNA targeting WT1-AS (sh-WT1-AS) or LV-WT1-AS. Mice were sacrificed 6 weeks after inoculation, and all organs were examined for the presence of macroscopic metastases. Lung metastatic nodules were determined under a dissecting microscope.

**Statistical analysis**

Results are presented as mean ± SD for the three repeated tests, the difference of two samples was compared using one-way ANOVA followed by post hoc Dunnett’s test or two-tailed Student’s t-test. P<0.05 was considered as significant.

**Results**

WT1-AS is downregulated in cervical carcinoma

In order to explore the expression of WT1-AS in the cervical carcinoma and control normal tissues, the levels of WT1-AS were analyzed in 63 pairs of cervical cancer tissues and matched paratumor tissues. WT1-AS was markedly downregulated in cervical carcinoma tissues than that in the control tissues. Additionally, the relatively lower level of WT1-AS was related to the advanced stages of cervical cancer and lymphatic metastasis. Next, we determined the prognostic significance of WT1-AS in patients with cervical cancer. We divided patients into WT1-AS low and WT1-AS high groups using the median value of 0.37 as a cutoff value. Kaplan–Meier analysis of 63 cases of patients with cervical cancer suggested that patients who had a lower level of WT1-AS exhibited a poor overall survival (Table S1). Then, we performed the ISH assay to further explore the level of WT1-AS in cervical carcinoma tissues. The level of WT1-AS was lower in tumor tissue than in paired peritumor tissue. To investigate the relationship of WT1-AS with the progression of cervical cancer, we analyzed the levels of WT1-AS in early cervical cancer (I) and advanced cervical cancer (II and III) tissues using the ISH assay. We found that advanced stages of cervical cancer (II and III) had relatively low levels of WT1-AS. Finally, WT1-AS levels were also detected in a panel of cervical cancer cell lines by qRT-PCR. Similar results were obtained in four cervical cancer cell lines in which the level of WT1-AS was lower in cervical cancer cell when compared with ECT1/E6E7. To identify the functions of WT1-AS in the growth of cervical cancer, we increased the expression of WT1-AS in cervical cancer cell using LV-WT1-AS. WT1-AS was significantly overregulated in LV-WT1-AS transfected SiHa and Ca-Ski cell. The MTT assay results showed that the overregulated of WT1-AS remarkably suppressed the growth of cervical cancer cell in vitro. Consistently, colony formation growth analysis revealed that upregulation of WT1-AS decreased the colony growth of cervical cancer cell. In order to confirm the role of WT1-AS on the proliferation of cervical cancer cell, SiHa and Ca-Ski cells were transfected with sh-Con or sh-WT1-AS. Then, the proliferation of SiHa and...
WT1-AS inhibits the aggressiveness of cervical cancer

Ca-Ski cells was measured by the MTT assay. As shown in Figure S1, downregulation of WT1-AS remarkably increased the growth of cervical cancer cell in vitro. Altogether, these results indicated that WT1-AS was downexpressed and associated with cervical cancer progression.

**Overregulation of WT1-AS inhibits cervical carcinoma cell migration and invasion**

In order to explore the impact of WT1-AS on the migration ability of SiHa and Ca-Ski cells, we performed the wound-healing assay, in which we found that the distance between wound edge of LV-WT1-AS transfect SiHa and Ca-Ski cells was markedly longer than those of control cell (Figure 1A). However, we found shorter distance between wound edge of sh-WT1-AS transfect SiHa and Ca-Ski cells compared with control cell (Figure 1C). To investigate the effect of WT1-AS on the invasion of cervical carcinoma cell, we performed a Transwell invasion assay, in which we found that overexpression of WT1-AS remarkably suppressed SiHa and Ca-Ski cell invasion (Figure 1B). As expected, we observed that sh-WT1-AS significantly accelerated the

invasion of cervical carcinoma cell (Figure 1D). Altogether, these findings suggested that WT1-AS inhibited cervical carcinoma cell migration and invasion in vitro.

**Overregulation of WT1-AS inhibits the growth of cervical carcinoma cells in vivo**

In vitro, WT1-AS inhibited cervical carcinoma cell growth, migration, and invasion. To investigate whether WT1-AS regulated the tumor growth of cervical carcinoma cell in vivo, SiHa cells that were transfected with LV-WT1-AS or LV-Vector were subcutaneously implanted into the nude mice. As shown in Figure 2A–2C, overexpression of WT1-AS remarkably inhibited the tumor growth of SiHa cell in vivo. To further analysis the impacts of WT1-AS on the tumor growth of SiHa cell in vivo, parental or WT1-AS downexpression SiHa cells were implanted into the nude mice to establish xenograft model. Downregulation of WT1-AS markedly accelerated the tumor growth of SiHa cell in vivo (Figure 2D–2F). To further investigate the role of WT1-AS in the metastasis of SiHa cell in vivo, an experimental metastasis assay was performed. SiHa cells that were transfected with sh-WT1-AS or LV-WT1-AS were injected into the lateral

tail vein of nude mice. Six weeks postinoculation, animals were sacrificed, and all the major organs were checked for the generation of tumor metastasis. The tumor metastasis was mainly observed in the lungs. We found that sh-WT1-AS resulted in the formation of numerous lung colonies, whereas upregulation of WT1-AS significantly suppressed pulmonary metastasis (Figure 2G). Finally, the Annexin-FITC/PI staining was conducted to determine the effect of WT1-AS on the apoptosis of SiHa cell. As shown in Figure 2H, the apoptosis of cell that was transfected LV-WT1-AS was markedly increased when compared with parental cell. All these results demonstrated that WT1-AS inhibited the growth, migration, and invasion of cervical carcinoma cell in vivo.

WT1-AS is a target of miR-330-5p

In order to better uncover the underlying mechanisms by which WT1-AS acts in cervical cancer, we selected the microRNA.org (http://34.236.212.39/microrna/home.do), an online bioinformatics tool, to predict the potential downstream target of WT1-AS.21 As shown in Figure 3A, miR-330-5p was the target of WT1-AS with binding sites. We then explored the level of miR-330-5p in both Ca-Ski and SiHa cells that were transfected with LV-WT1-AS. As shown in Figure 3B, the level of miR-330-5p was inhibited when cell was transfected with LV-WT1-AS. Next, we transfected two cervical cancer cell lines with miR-330-5p mimics and found that miR-330-5p remarkably inhibited the expression of WT1-AS (Figure 3C and D). To future prove that WT1-AS directly binds to miR-330-5p, the luciferase reporter assay was carried out. The wt-WT1-AS or mut-WT1-AS was inserted into pmirGLO luciferase target expression vector. Then, plasmid was transfected into HEK-293T cell combine with miR-330-5p or miR-NC. The luciferase activity of HEK-293T cell that was transfected with wt-WT1-AS was decreased by miR-330-5p. Nevertheless, the inhibition effect of miR-330-5p was abolished in HEK-293T cell that was transfected with mut-WT1-AS (Figure 3E). Finally, the level of miR-330-5p was found inversely associated with the level of WT1-AS in cervical cancer tissue (Figure 3F). Therefore, these results demonstrated that IncRNA WT1-AS directly bound to miR-330-5p. We then examined whether miR-330-5p could affect cervical cancer cell growth and aggressiveness. As shown in Figure 3G–J, upregulation of miR-330-5p strongly promoted, while silencing miR-330-5p decreased the colony formation and invasion of SiHa cell, which indicated that miR-330-5p facilitated cervical carcinoma cell aggressiveness malignant phenotypes in vitro. E6/ E7 protein is important for proliferation in cervical cancer cell. We next detected the role of miR-330-5p on the expression of HPV E6 and HPV E7. As shown in Figure S2, the protein expression of HPV E6 and HPV E7 in SiHa cell were slightly increased by miR-330-5p transfection.

Upregulation of miR-330-5p neutralizes the inhibitory effect of WT1-AS on cervical cancer cell

In order to analysis the levels of miR-330-5p in cervical carcinoma and control normal tissues, the levels of miR-330-5p were detected in 63 pairs of cervical cancer tissues and matched paratumor tissues. As shown in Figure 4A, the levels of miR-330-5p in cervical carcinoma tissues were much higher than that in the control. Additionally, the relatively higher level of miR-330-5p was related to the advanced stages of cervical cancer and lymphatic metastasis (Figure 4B and C). Kaplan–Meier analysis of 63 cases of patients with cervical cancer suggested that higher level of miR-330-5p was associated with the poor overall survival (Figure 4D and Table S2). Similar results were obtained in four cervical cancer cell lines in which the level of miR-330-5p was increased in cervical cancer cell when compared with ECT1/E6E7 cell (Figure 4E). Although we have identified that WT1-AS was the target of miR-330-5p, the precise roles of miR-330-5p in WT1-AS-mediated cervical cancer cell growth and aggressiveness were unknown. To solve this problem, SiHa cell was cotransfected with miR-330-5p along with WT1-AS (data not shown) and, then, colony formation and invasion assays were conducted. As shown in Figure 4F and G, overregulation of miR-330-5p in SiHa cell, which stably pretransfected with LV-WT1-AS, remarkably counteracted the suppressive effect of WT1-AS on SiHa cell colony formation and invasion. Moreover, SiHa cell was co-transfected with miR-330-5p inhibitor along with sh-WT1-AS and both colony formation and Transwell assays were conducted. As expected, miR-330-5p inhibitor significantly decreased the growth and invasion of SiHa cell that was increased by sh-WT1-AS (Figure 4H and I). Altogether, our study demonstrated that WT1-AS regulated cervical carcinoma cell growth, migration, and invasion through miR-330-5p.

WT1-AS serves as a ceRNA of p53 through binding to miR-330-5p

The binding site between miR-330-5p in p53 was predicted using the bioinformatics analysis (Figure 5A). The eleven common potential target genes that were obtained from three bioinformatics analysis tools (TargetScan, miRTarBase, and miRDB) are summarized in Figure S3A and B. miRDB
was found to bind p53 with a minimum free energy of −32.3 kcal/mol (Figure S3B). In order to identify the direct gene of miR-330-5p, the mRNA levels of these genes in miR-330-5p- or miR-NC-transfected SiHa cell were detected using the qRT-PCR assay. As shown in Figure S3C, the mRNA level of p53 was significantly inhibited by miR-330-5p in SiHa cell. Then, transfection of miR-330-5p into HEK-293T cell significantly inhibited the luciferase activity of p53-wt, whereas miR-330-5p transfection did not suppress the luciferase activity of p53 when the binding sites were mutated (Figure S5B). To confirm that p53 was the potential target of miR-330p, the expression of p53 in SiHa and Ca-Ski cells that were transfected with miR-NC or miR-330-5p was measured by qRT-PCR and immunofluorescence. As shown in Figures S5C and D, miR-330-5p transfection markedly decreased the level of p53 in cervical cancer cell. In addition, the expression of p53 was analyzed in 63 pairs of cervical cancer tissues and matched paratumor tissues. As shown in Figure SE, the levels of p53 in cervical carcinoma tissues were much lower than those in the control tissues. Additionally, the relatively lower level of p53 was related to advanced stages of cervical cancer and lymphatic metastasis (Figure S5F and G). Kaplan–Meier analysis of 63 cases of patients with cervical cancer suggested that patients had a lower level of p53 exhibited the poor overall survival (Figure S5H and Table S3). To define the expression of p53 in cervical carcinoma, we checked the

expression of p53 in peritumor and cervical carcinoma tissues by immunohistochemical staining with p53 antibody. We found that p53 exhibited lower level in cervical cancer tissue (Figure 5I). Importantly, the levels of miR-330-5p were found inversely associated with the expression of p53 in cervical carcinoma tissues (Figure 5J). Finally, similar results were obtained in four cervical cancer cell lines in which p53 was downexpressed in cervical cancer cell compared to ECT1/E6E7 cell (Figure 5K).

To further confirm whether WT1-AS regulated p53 expression by sponging miR-330-5p, SiHa, or Ca-Ski cell was transfected with LV-WT1-AS. We found that WT1-AS over-

(C) miR-330-5p reduced the mRNA expression of p53 in SiHa and Ca-Ski cell. (D) miR-330-5p inhibited the expression of p53 in SiHa and Ca-Ski cell as shown in immunofluorescence analysis. (E) Total RNA was extracted from the paratumor and tumor tissues from patients with cervical cancer, and the mRNA level of p53 was determined by qRT-PCR assay. (F) Representative association between p53 expression and I or II–III tumor stage was shown. **P<0.01 compared to I. (G) Relative levels of p53 in metastatic and nonmetastatic cervical cancer tissues. ***P<0.01 compared to nonmetastasis. (H) Overall survival analysis of cervical cancer patients with high or low level of p53. (I) The expression of p53 in peritumor and cervical cancer tissue was analyzed by immunohistochemical assay. (J) Association between p53 and miR-330-5p in cervical cancer tissue was evaluated. (K) The level of p53 in four cervical cancer cell lines and ECT1/E6E7 cell was detected by qRT-PCR analysis. **P<0.01 compared to ECT1/E6E7 cell.

Abbreviation: qRT-PCR, quantitative real-time PCR.
expressing increased the level of p53, whereas upregulation of miR-330-5p in the meantime reversed this trend (Figure 6A).

In order to prove that WT1-AS-mediated regulation on the expression of p53 is through miR-330-5p, SiHa or Ca-Ski cell was transfected with sh-WT1-AS alone or cotransfected with sh-WT1-AS and miR-330-5p inhibitor. Then, the level of p53 was assayed using the qRT-PCR assay. As shown in Figure S4, sh-WT1-AS decreased the level of p53, whereas downregulation of miR-330-5p rescued the inhibitory effect of WT1-AS on the level of p53. Previous assays demonstrated that miR-330-5p attenuated the suppressive impacts of LV-WT1-AS on cervical cancer cell (Figure 4F–I). Then, we analyzed whether the impacts of WT1-AS on cervical cancer cell were regulated by miR-330-5p/p53. Two cervical cancer cell lines were cotransfected with sh-WT1-AS and LV-Vector or LV-p53 (Figure 6B). We revealed that the aggressiveness abilities of SiHa cell that were increased by the downregulation of WT1-AS were inhibited by the overexpression of p53. Upregulation of p53 markedly decreased the migration and invasion abilities of cervical cancer cell (Figure 6C–E).

Figure 6 WT1-AS inhibits cervical cancer cell colony formation, migration, and invasion via regulation of miR-330-5p/p53 axis.
Notes: (A) The level of p53 was assayed in cell co-transfected with miR-330-5p alone or LV-WT1-AS combination with miR-330-5p. (B) Cell was co-transfected with sh-WT1-AS alone or sh-WT1-AS combination with LV-p53, and the level of p53 was determined by qRT-PCR analysis. (C) Cell was co-transfected with sh-WT1-AS alone or sh-WT1-AS combination with LV-p53, and colony formation assay was conducted. (D) Cell was co-transfected with sh-WT1-AS alone or sh-WT1-AS combination with LV-p53, and wound-healing assay was performed. (E) The invasion of transfected cell was determined by Transwell assay. (F) Schematic illustration of the positive feedback loop. WT1-AS upregulated p53 by binding to and suppressing miR-330-5p. **P<0.01 compared to sh-Con, ##P<0.01 compared to sh-WT1-AS + LV-Vector.

Abbreviations: LV-WT1-AS, lentiviral vector encoding WT1-AS cDNA; qRT-PCR, quantitative real-time PCR; sh-WT1-AS, shRNA targeting WT1-AS; WT1-AS, WT1 antisense RNA.
In general, these results indicated that WT1-AS served as a ceRNA to regulate the expression of p53 via sponging miR-330-5p (Figure 6F).

Discussion

Cervical cancer is one of the most aggressive tumors, and the occurrence of metastasis led to a sharp decline in survival rate of patients. Thus, identification of metastatic-related biomarkers and therapeutic targets will help improve the prognosis of patients with cervical cancer. Recently, lncRNAs have been proved to be involved in the invasion and metastasis of cancer and have been shown to be potentially noninvasive biomarkers in various cancers. Here, we reported that WT1-AS was a novel metastasis-associated lncRNA that played a significant role in the regulation of cervical carcinoma growth and metastasis. We found that WT1-AS was significantly downregulated in cervical carcinoma tissue and cervical cancer cell. In addition, overexpression of WT1-AS inhibited the aggressiveness and migration of cervical cancer cell in vitro. Consistently, overexpression of WT1-AS suppressed the growth of cervical cancer cell in vivo. In conclusion, our results suggested that metastatic-associated WT1-AS was not only a potential biomarker but also a valuable therapeutic target for cervical cancer.

Recently, substantive gene expression investigations of cancer have identify that a great quantity of lncRNAs are dysregulated in diverse cancer types. For example, lncRNA H19 inhibits cells’ growth, mobility, and invasion through downregulation of IRS-1 in thyroid cancer cell. lncRNA ATB is upregulated in osteosarcoma and positively associated with Enneking stage, metastasis, and recurrence. Meanwhile, overexpression of lncRNA ATB promotes osteosarcoma cell growth and aggressiveness by inhibiting miR-200s. In addition, lncRNA GPX4 participates into metastasis and regulates EMT process in colorectal carcinoma through competing for miR-200b-3p to future modulate the expression of ZEB1. Previous studies have convinced that the level of FENDRR is remarkably downexpressed in gastric carcinoma tissue and cell when compared with the corresponding normal specimen and normal epithelial cell line.

To explore the precise roles of WT1-AS in cervical cancer cell, Ca-Ski and SiHa cells were selected and transfected with sh-WT1-AS and LV-WT1-AS, respectively. Overregulated WT1-AS inhibited the growth of cervical cancer cell as demonstrated in MTT and colony formation analysis, whereas downexpression of WT1-AS facilitated cell growth and colony formation. After demonstrating that WT1-AS inhibited the growth of cervical cancer cell in vitro, we next investigated the role of WT1-AS on cervical cancer cell in vivo. As expected, overregulation of WT1-AS remarkably decrease cervical cancer cell growth in vivo. Cancer cell metastasis is the major cause of death in patients with cancer. The initial steps of metastatic cascade include local invasion and migration, EMT, and intravasation. IncRNAs are emerging as key regulators governing biological processes of metastasis, including migration and invasion. In this work, wound healing and Transwell experiments were executed to verify whether WT1-AS regulated the migration and invasion ability of cervical cancer cell. All these findings suggested that both migration and invasion abilities of cervical carcinoma cell were inhibited by overregulation of WT1-AS.

Emerging evidence prove that IncRNAs are the endogenous miRNA sponges and competitively bind to miRNAs to future mediate genes’ expression. In order to explore whether WT1-AS acts as a miRNA sponge, the bioinformatics method was utilized and the result suggested that there were binding sites between miR-330-5p and WT1-AS and the following investigations confirmed that miR-330-5p was negatively regulated by WT1-AS. The luciferase activity assays verified that the luciferase activity was remarkably reduced in miR-330-5p and lncRNA WT1-AS wt cotransfection cell. Subsequently, miR-330-5p was demonstrated to reverse the roles of WT1-AS on the growth and malignant phenotypes of cervical cancer cell. miR-330-5p inhibitor transfected significantly decreased the growth and aggressiveness of cervical carcinoma cell that were increased by sh-WT1-AS, whereas overexpression of miR-330-5p reversed the inhibitory impacts of WT1-AS on the colony formation and invasion of cervical carcinoma cell.

One function of IncRNAs is to act as a ceRNA to sponge miRNAs. It is well known that miRNAs regulate the expression of target gene by binding to the 3’-UTR of gene. In our study, bioinformatics analysis was selected to predict the target gene and p53 was selected as the potential target gene. The luciferase reporter analysis, which is the direct method
for target validation, also confirmed that p53 was the direct target of miR-330-5p. In cervical carcinoma, two viral genes, HPV E6 and HPV E7, are expressed and act cooperatively to promote tumorigenesis.30 The HPV E6 oncoprotein interacts with several cellular proteins, thereby activating a number of oncogenic pathways that lead to the blockage of apoptosis, alterations of the transcription machinery, interference with cell–cell interactions, and cell immortalization.31 One of the most investigated oncogenic activities of “high-risk” mucosal HPV E6 proteins is the ability to inactivate the tumor suppressor p53 by targeting it to degradation.32 We also explored the impact of miR-330-5p on the expression of HPV E6 and E7 and found that the expression of E6 and E7 were slightly increased by miR-330-5p in cervical cancer cell, suggesting that the suppressive role of miR-330-5p on the expression of p53 was associated with its regulation of HPV E6/E7. More importantly, the rescue experiments proved that miR-330-5p/p53 mediated the impacts of WT1-AS on cervical cancer cell, which revealed an IncRNA WT1-AS/miR-330-5p/p53 axis. In conclusion, WT1-AS inhibited cell growth and aggressiveness in cervical cancer cell, miR-330-5p was a target of WT1-AS, and alternation of oncogenic pathways that lead to the blockage of apoptosis in hepatocellular carcinoma through down-regulating of WT1.17
