Abstract

Background: Gender medicine focuses on how gender differences affect health status and diseases development and how they influence health services access and attitude to screening programmes. Endocrine diseases are influenced by many gender-related issues, some of which have not been sufficiently investigated. The aim of this study was to evaluate gender difference in determinants of health (as lifestyle, level of education, area of origin, distance from hospital) and how these elements could influence diseases prevalence in an endocrine outpatients setting, with a special focus on oncological disease.

Methods: We performed a cross-sectional study enrolling patients referring for the first time to our Oncological Endocrinology Unit, between January 2019 to December 2019.

Results: We enrolled 1107 consecutive patients. Mean age was 56.8 ± 15.0 years (77% females). The main reasons for referral were thyroid and bone diseases. We found a gender difference in some disease prevalences: malignant endocrine diseases and iatrogenic thyroid diseases were more frequent in males, while other thyroid disorders, adrenal and metabolic diseases and cancer treatment induced bone loss were higher in females. The frequency of oncological comorbidities was higher in females. No difference was found in the propensity to travel long distances to reach the hospital. In our population, women had a higher socio-cultural level and followed healthier lifestyle. In fact, alcohol and tobacco consumption was lower in females and women had lower BMI. The percentage of smokers or ex-smokers was higher in patients with any malignancy compared to patients with benign endocrine diseases.

Conclusions: the study showed the importance of considering gender as a determinant of health, able to influence also lifestyle and habits, and as an element to keep in consideration to promote a healthier lifestyle and a targeted endocrine screening especially in oncological setting.

Keywords: gender medicine; lifestyle; endocrine disease; oncological comorbidities; determinants of health.
Gender medicine deals with biological, psychological and socio-cultural differences between men and women, which can affect health status and disease development(1). The term "gender" goes beyond the simple biological differences between male and female, classically defined as "sex", taking into account also environmental, social, cultural and relational factors(2). Gender medicine is therefore a complex study of how these gender differences affect the state of health, the onset and progression of diseases, the access to health services, the attitude towards prevention interventions and to therapeutic strategies(3). In fact, men and women, despite being susceptible to almost the same pathologies, could present different symptoms, disease progression and response to treatments. In addition, women have a higher propensity to consult health care providers, generally they take more medication and usually manage family health problems(4).

In 2019, Italian Ministry of Health arranged a plan for the application and the diffusion of gender medicine in the country, testifying its importance in the wider field of precision medicine(5). Gender medicine therefore aims to achieve a "health" condition by paying attention not only to the disease itself, but also to the “determinants of health” starting from lifestyles such as alcohol, smoking, physical activity, nutrition and body weight(6). These, in fact, contribute to determining the health of women and men and have an impact on the incidence of many chronic diseases, such as cardiovascular and respiratory diseases, diabetes mellitus, and cancer diseases. Exposure to the aforementioned risk factors depends on individual choices, but it is strongly influenced by the socio-cultural and environmental context and therefore by gender(7).
In modern society, gender medicine appears essential to achieve the best diagnostic and therapeutic work-up for both men and women and to optimize health services planning.(8).

Endocrinology is one of the medical disciplines most influenced by issues related to gender, as the most widespread endocrine diseases (e.g. thyroid diseases, osteoporosis and diabetes mellitus) have marked gender differences in term of prevalence. This is certainly due to hormonal differences between males and females, while the impact of gender-related determinants of health have not yet been sufficiently investigated.(9).

The aims of our study were:

- to evaluate the gender difference in determinants of health as lifestyle, level of education, area of origin;
- to evaluate how and if these determinants could influence the prevalence of endocrine diseases and oncologic disease;
- to assess gender difference in availability to travel long distances in order to gain access to health services.

**Methods**

This is a cross-sectional study, conducted in our Oncological Endocrinology Unit at Regina Elena National Cancer Institute of Rome, between January 2019 to December 2019.

All patients (age > 18 years) referring to our endocrine center, for the first evaluation in the study frame-time, were considered potentially eligible. Patients could gain access to our center through national health system booking service or through selected waiting lists accessible by our hospital’s oncologists.
The following parameters were assessed during first visit: sex, age, residence address to calculate distance from the hospital, ethnicity and nationality, level of education (grade 8 or less: elementary school and middle school; grade 12 or upper education: high school, degree or upper title), body mass index (BMI) calculated as the weight (kilograms) divided by the height (meters squared), smoking status (3 groups: smokers, non-smokers or ex-smokers), alcohol consumption (classified as yes in case of at least 0.5 UI alcohol units per day or no), physical activity (no, yes moderate or yes intense), endocrine and oncological diseases (for example: brain, breast, prostate, lung, gastrointestinal cancers, hemato-lymphoid neoplasms).

Endocrine diseases were grouped as follows: pituitary diseases, andrological diseases, neuroendocrine neoplasms, thyroid cancers, benign thyroid diseases (including thyroid nodules, thyroiditis, primary hyperthyroidism and hypothyroidism, iatrogenic thyroid disorders induced by amiodarone, tyrosine kinase inhibitors-TKI, immune checkpoint inhibitors, neck radiotherapy), bone diseases (including cancer treatment induced bone loss-CTIBL, post-menopausal osteoporosis and osteopenia, hyperparathyroidism and hypercalcemia), adrenal diseases (including adrenal hyperplasia, functioning and non-functioning adrenal adenomas and incidentalomas), diabetes mellitus and metabolic diseases (including diabetes mellitus type 2, obesity, insulin resistance). Each patient’s data were collected using a standardized data collection form.

The study was done under the approval of the local ethic committee of Regina Elena National Cancer Institute and all patients gave written informed consent to participate.

2.1. Statistical analysis
Variables of interest were expressed as frequencies and percentage values while continuous variables were expressed as mean ± standard deviation. Patients were divided in subgroups according to gender and age. Associations among variables were tested with non-parametric Chi-square test. Statistically significance was defined at p<0.05. All statistical analyses were performed using Statistical Packages for Social Sciences (SPSS version 21.0).

**Results**

**3.1. Patients’ characteristics**

In the study timeframe (one year), a total of 1180 patients referred to our endocrine center for first examination. 73 patients were excluded from the study due to missing data or refusal to participate, so a total of 1107 patients were enrolled in the study: 854 patients were females (77%) and 253 were males (23%). Total mean age was 56.8 ± 15.0 years, with a statistically significant difference between gender (male: 60 ± 16.6 years, female 56 ± 14.3 years, p<0.001). No gender difference was found in ethnicity of patients. A higher proportion of female patients had a nationality other than Italian (p=0.008, 29 patients from European Union, 5 from South America, 16 from Asia, 2 from Africa).

**Table 1. Patients’ characteristics.**

|                      | Male     | Female   | p value |
|----------------------|----------|----------|---------|
|                      | N= 253 (23%) | N=854 (77%) |         |
| Age                  | 60 ± 16.6 | 56 ± 14.3 | <0.001* |
| Age ≤ 45 years       | 50 (19.9%) | 202 (23.7%) | 0.209#  |
| Age > 45 years       | 201 (80.1) | 650 (73.6%) |         |
| Ethnicity            |          |          |         |
| Caucasian n (%)      | 250 (98.8%) | 839 (98.6%) | 1.0#    |
| Others n (%)         | 3 (1.2%) | 12 (1.4%) |         |
### Nationality

|        | Our Center | Reference | p-value |
|--------|------------|-----------|---------|
| Italian| 249 (98.4%)| 806 (94.4%)| 0.008*# |
| Others | 4 (1.6%)   | 48 (5.6%)  |         |

### Level of education

|                   | Our Center | Reference | p-value |
|-------------------|------------|-----------|---------|
| Grade 8 or lower  | 86 (38.2%) | 239 (30.3%)| 0.024** |
| Grade 12 or upper | 139 (61.8%)| 551 (69.7%)|         |

### Distance from the hospital

|                  | Our Center | Reference | p-value |
|------------------|------------|-----------|---------|
| ≤ 10 Km          | 51 (20.2%) | 189 (22.1%)| 0.229#  |
| 10-20 Km         | 79 (31.2%) | 223 (26.1%)|         |
| 20-30 Km         | 39 (15.4%) | 169 (19.8%)|         |
| >30 Km           | 84 (33.2%) | 272 (31.9%)|         |

### Determinants of health

#### BMI

|                  | Our Center | Reference | p-value |
|------------------|------------|-----------|---------|
|                  | 27.8 ± 5.0 | 26.1 ± 5.5| <0.001* |

#### Smoking status

|                      | Our Center | Reference | p-value |
|----------------------|------------|-----------|---------|
| Smokers or ex-smokers| 150 (59.8%)| 356 (42.0%)| <0.001**|
| No smokers           | 101 (40.2%)| 492 (58.0%)|         |

#### Alcohol Consumption

|                | Our Center | Reference | p-value |
|----------------|------------|-----------|---------|
| No             | 125 (50.8%)| 559 (67.0%)| <0.001* |
| Yes            | 121 (49.2%)| 275 (33.0%)|         |

#### Physical activity

|                  | Our Center | Reference | p-value |
|------------------|------------|-----------|---------|
| No               | 139 (65.0%)| 468 (63.8%)| 0.854#  |
| Yes, moderate    | 69 (32.2%) | 240 (32.7%)|         |
| Yes, intense     | 6 (2.8%)   | 26 (3.5%)  |         |

table.

### 3.2. Reason for referral

Patients of both genders referred to our center mainly for thyroid diseases. The secondary most frequent reason was bone disease. Among patients referring for benign endocrine diseases, there was a high prevalence of oncological comorbidity. In fact, at list one malignancy was present in 56.1% of patients with benign endocrine disease compared to only 14.5% of patients with endocrine malignancies, with a statistically significant difference (p<0.001). Considering gender,
malignant endocrine diseases were more frequent in males than in females (11.5% vs 5.3%, p<0.001). All reasons for referral are summarized in Table 2.

**Table 2. Reasons for referral.**

| Reason                        | Male N= 253 (23%) | Female N=854 (77%) |
|-------------------------------|------------------|--------------------|
| Benign thyroid diseases       | 147 (58.1%)      | 476 (55.7%)        |
| Thyroid cancers               | 19 (7.5%)        | 39 (4.6%)          |
| Bone diseases                 | 22 (8.7%)        | 247 (28.9%)        |
| Adrenal diseases              | 21 (8.3%)        | 37 (4.3%)          |
| Pituitary diseases            | 9 (3.6%)         | 14 (1.6%)          |
| Neuroendocrine neoplasms      | 10 (4.0%)        | 6 (0.7%)           |
| Diabetes mellitus and metabolic diseases | 9 (3.6%)       | 18 (2.1%)          |
| Andrological diseases         | 9 (3.6%)         | NA                 |
| Others                        | 7 (2.8%)         | 17 (2.0%)          |

Values are expressed as number of patients (percentage). NA= not applicable.

3.3. Disease prevalence according to gender

Most patients referred to our Unit for just one endocrine disease (corresponding to the reason for referral), while a lower but significant percentage of patients had more than one disease: in particular, 227 patients had two endocrine diseases and 23 patients had 3 endocrine diseases. Global diseases prevalence is summarized in Table 3. The most frequent group of disorders were benign thyroid diseases, without gender difference (p= 0.517). In a subgroup analysis, percentage of iatrogenic thyroid disorders (induced by amiodarone, TKI, immune checkpoint inhibitors, neck radiotherapy) was higher in males (10.6%, vs1.4% in females, p<0.001), while no statistically significant difference was found in percentage of patients with thyroid nodules according to gender (70% in males, 69.9% in females, p= 0.77). Consequently,
females had higher prevalence of remaining thyroid diseases (hypothyroidism and hyperthyroidism, thyroiditis).

There was a statistically significant difference in the proportion of females and males affected by bone diseases (respectively, 36.1% vs 10.7%, p < 0.001); in this group most patients had CTIBL and only a minority of patients had other bone diseases not related to cancer, such as post-menopausal osteoporosis or disorders of calcium metabolism in both gender. Considering CTIBL prevalence, there was a statistically significant difference between males and females (27.3% vs 7.1%, p < 0.001).

In our population, there was no gender difference in the prevalence of pituitary diseases (p = 0.288), while adrenal and metabolic diseases were higher in females (respectively p = 0.002 and p = 0.024).

Considering malignancies, a higher proportion of males referred for neuroendocrine neoplasms (4.0% vs 0.7%, p < 0.001) and thyroid cancers (7.9% vs 4.7%, p = 0.047), while females had a higher prevalence of oncological comorbidities than males (p = 0.005). In the subgroup of patients affected by oncological comorbidities, a higher percentage of women had CTIBL than men (45.0% vs 16.1%, p < 0.001).

Table 3. Diseases prevalence

| Disease                                | Male N=253 (23%) | Female N=854 (77%) |
|----------------------------------------|------------------|-------------------|
| Benign thyroid diseases                | 160 (63.2%)      | 559 (65.5%)       |
| Thyroid cancers                        | 20 (7.9%)        | 40 (4.7%)         |
| Bone diseases                          | 27 (10.7%)       | 308 (36.1%)       |
| Adrenal diseases                       | 23 (9.1%)        | 35 (4.1%)         |
| Pituitary diseases                     | 9 (3.6%)         | 20 (2.3%)         |
| Neuroendocrine neoplasms               | 10 (4.0%)        | 6 (0.7%)          |
| Diabetes mellitus and metabolic diseases | 27 (10.7%)    | 55 (6.4%)         |
| Andrological diseases                  | 9 (3.6%)         | NA                |
| Others          | 7 (2.8%) | 19 (2.2%) |
|----------------|---------|---------|
| Oncological comorbidities | 115 (45.5%) | 474 (55.5%) |

This Table takes in consideration all patients diseases. Values are expressed as number of patients (percentage). NA= not applicable.

3.4. Gender-related determinants of health

No difference was found in physical activities between males and females (p=0.854), and this data was confirmed also dividing patients in two age groups (under and over 45 years).

Men had a statistically significant higher BMI compared to women (27.8 ± 5.0 vs 26.1 ± 5.5 kg/m², p<0.001). A higher proportion of males was smokers or ex-smokers compared to females (p<0.001); accordingly, 58% of women had never smoked in their life compared to only 42% of males. Dividing the study population in two groups according to age, in younger people there was no statistically significant difference in smoking habits regarding to sex, while in people older than 45 years there was a statistically significant gender difference in the proportion of smokers (p<0.001). Also alcohol consumption was higher in males than in females (49.2 vs 33.0%, p<0.001). As smoking habits, there was a difference in alcohol habits only in older patients(p<0.001).

No difference was found in smoking status, physical activity and alcohol consumption regarding nationality (comparing Italian and foreign patients), neither between patients referring for benign and malignant endocrine diseases. However, gathering together people with any malignancies, both endocrine or non-endocrine, the percentage of smokers or ex-smokers was higher compared to the group without malignancies (p=0.041), while no difference in proportion was found regarding physical activity and alcohol consumption.
In our study population, women had a higher level of education compared to men (p=0.024), as well as not Italian people had more frequently a degree or upper title compared to Italian patients (39.1% vs 23%, p= 0.02).

Only 22% of patients lived nearby the hospital (<10 km). The prevalence of malignant endocrine disease was 7.7% in the group of patients who lived far from the hospital (>10 km) versus 3.8% in patients who lived closer (p= 0.031). No significant difference was found in the distance from the hospital according to gender, nationality or non-endocrine oncological comorbidities.

Gender-related determinants of health are summarized in Table 1.

Discussion

Gender medicine has recently received increasing attention(10). In this perspective, we decided to design this cross-sectional study in order to provide an overview of our patients, focusing on the role of gender on endocrine diseases, risks factors and other important aspects related to health care, always in a gender perspective. Many studies in the literature have focused on the impact of gender on lifestyle(11). Men seem more prone to consume alcohol and to develop alcohol-related diseases compared to women(12). Conversely, women who physiologically tolerate lower amount of alcohol (due to the sex differences in gastric absorption and metabolism), usually drink less alcohol also for cultural reason, as society's disapproval of drinking or increased risk of physical and sexual assault(12, 13).

In our population, we confirmed a gender difference in alcohol consumption, which was lower in females. Interestingly, this difference was not statistically significant in younger people, testifying as younger women have a more similar lifestyle to males, perhaps due to female emancipation,
while in older people traditional gender differences are yet more preserved. Likewise, a higher proportion of men was smokers than women. In Italy, data from two recent tobacco use surveys show a smoking prevalence of 26% in men compared to 17.2% in women. This gender difference is reduced in young adults: in Italian adolescents (15-24 years), 21.9% of boys are smokers against 18.2% of girls. Therefore, these studies underline that the use of tobacco in young women is a behavior to be monitored carefully. The relevant gender difference in tobacco use has been confirmed by Italian Ministry of Health, in a Tobacco Prevention and Control Report based on ISTAT data: the estimated smoking prevalence is 19.8% (24.8% males and 15.1% females). These data are consistent with our results: in the whole study population, men were more frequently smokers or ex-smokers compared to women but, considering only patients aged 45 or less (born after Italian women emancipation) this difference has not been confirmed, testifying to a change in lifestyle in new generations. Several factors should be considered in the relationship between smoking and female gender. Low sociocultural and educational levels and living in developing countries are known to be risk factors for the onset of tobacco consumption. In the last years the proportion of women who become smoker has increased, mainly due to women’s earning power and targeted marketing by tobacco companies.

Scientific research has also shown differences in food intake and the practice of physical activity in both sexes. For example, in modern Western societies, the male gender seems to prefer red meat, high protein foods and sugar-sweetened beverages, while healthier foods such as vegetables, fruit, fish and dairy products are mostly eaten by women. These differences may depend on a different awareness of the relationship between food behavior and health and on a different
attention to weight control or good physical shape, in line with modern society stereotypes (23).

This attitude is reflected in the nutritional pattern and body mass index. Unfortunately, we did not collect information on dietary habits of our patients, but males had a higher BMI compared to women, testifying to probably less healthy dietary habits. In our population, there were no differences in physical activity level between males and females, unlike other studies published in literature which have shown, especially in younger people, a greater propensity to physical activities in males than in females (24, 25).

Taking all these aspects together, in our study population, women seem to follow a healthier lifestyle. This data could depend on the influence of multiple factors. First, women pay greater attention to their health condition compared to men (4); secondary, it is the conditioning of society that leads women to maintain a good body shape in order to achieve beauty stereotypes; finally, the level of education of patients. Indeed, in our population, women had a higher level of education compared to men and this could have affected the lifestyle of our patients. It is demonstrated that better educated people follow a healthier lifestyle, probably due to the increased awareness of the correlation between lifestyle and health (26).

National habits also seem to influence the state of health; in fact, in our study, foreign people (mainly women from European Union States) did not follow a healthier lifestyle than Italian patients, despite their higher education level.

During a year, the percentage of women referring for a first endocrine visit was significantly higher than men. This fact could be explained by the more common prevalence of endocrine diseases in
females (27), but also by the higher attention paid to personal health status typical of women and
their higher propensity to refer to health care centers (1).

One of the aims of our study was to ascertain if women were more willing than men to travel long
distances for obtaining medical care. The willingness to move from own home area to reach
tertiary center health care was the same in both sexes and did not change according to nationality;
in fact, most patients decided to go to a qualified cancer endocrinology center, even if it was not
close to their residences. This was particularly true for patients with endocrine tumors who showed
a higher propensity to travel long distances. It is important to consider that a relevant part of the
first access to our center was allowed regardless of the reported disease, considering that the
booking service of the Italian public health system does not indicate to the patients the most
suitable hospital. According to this, the reason for referral to our center was only partially biased
by the type of center (Oncological Endocrine Unit).

The most common reason for referral to our center was an endocrine malignancy or a benign
endocrine disease associated to other oncological comorbidities, probably because our center is a
national reference hospital for neoplastic diseases. In our population, women had a higher
prevalence of oncological comorbidities: a high percentage of these patients referred to the
Endocrine Unit for prevention and treatment of cancer induced bone loss, mainly due to the intake
of aromatase inhibitors or gonadotropin-releasing hormone analogs for breast cancers.

Benign thyroid diseases were the most common endocrine disorders in both sexes; this finding
could be explained by the high prevalence of thyroid nodules. The increased prevalence in our
population could be caused by the fact that oncological patients undergo multiple and deepened
whole body radiological examinations (such as computed tomography and magnetic resonance imaging) and functional procedures (such as positron emission tomography), therefore thyroid nodules can be an accidental finding(28), and patients have been referred to our Unit for subsequent tests, such as the fine needle aspiration diagnostic biopsy of the thyroid nodule.

Furthermore, there was no gender difference in the prevalence of benign thyroid disease, although some disorders, such as Hashimoto's thyroiditis or thyroid nodules, are known to be more frequent in females(27). However, this finding could be explained considering that in our population this group of diseases also contains drug related thyroid dysfunction (e.g. due to TKI or amiodarone intake) or subclinical thyroid disease due to age or chronic diseases, which usually do not showed significant gender differences(29, 30).

Probably, the high incidence of adrenal incidentalomas could be explained by the high number of radiological and functional tests performed in our Hospital for the cancer diagnosis and for patients’ follow-up.

In our study, thyroid malignancies were more frequent in males than females. The risk of malignancy of the thyroid nodules is known to be greater in males(31, 32), and that male gender is an independent prognostic factors in papillary thyroid carcinoma, which influences staging and risk of recurrence(33, 34). These factors together could explain the propensity to refer to a national cancer center in male patients.

We therefore sought to evaluate the impact of common gender-influenced risk factors in the higher prevalence of endocrine malignancies found in males.
In patients with at least one tumor (endocrine or non-endocrine), the percentage of smokers and ex-smokers was higher compared to patients without neoplasms. This finding has not been confirmed considering only patients with endocrine malignancies, probably due to the low number of patients affected and also considering that for some of these malignancies (for example thyroid cancer) other risk factors are of considerable importance, such as family history or previous radiation exposure (32, 35).

In a gender medicine perspective, it should be also interesting to evaluate possible differences between men and women in terms of inclination in carrying out periodic follow-up visits and adherence to the treatment proposed by physician, with possible impact on progression and outcomes of the endocrine disorders. Unfortunately, we do not have data on these aspects in our population, as only one visit per patient has been analysed, but this topic is of a great interest for further studies.

**Conclusions**

Biological and sociocultural aspects are known to influence lifestyle, patient health, disease development and treatment adherence. The study highlights and confirms the importance of considering gender and gender-related health determinants as key factors for health, even in patients affected by endocrine diseases, in which this approach has not been widely used.

Our study demonstrated that smoking and alcohol consumption are more common in males and younger women. Therefore, in the approach to the patient, doctors should pay special attention to female and male lifestyle, in order to discourage voluptuous habits and to encourage physical activity and healthy eating habits. This is particularly important mainly in subjects who, nowadays,
seem to be less careful to these aspects, as men, younger women or patients with lower socio-cultural level.

Our study confirmed, as already known in the literature, that women were more affected by endocrine disorders but, in our cohort, the proportion of endocrine malignancies was higher in men. Therefore, from a precision medicine perspective, all efforts must be made to raise awareness, in oncological patients and health care providers, on the risk of endocrine diseases development in order to promote targeted screening in both genders.

**List of abbreviations:**

TKI: tyrosine kinase inhibitors; CTIBL: cancer treatment induced bone loss; BMI: body mass index.
