Malignant mesothelioma is a form of cancer that is highly resistant to conventional cancer therapy for which no major therapeutic advances have been introduced. Here, we identify gremlin-1, a known bone morphogenetic protein inhibitor crucial for embryonic development, as a potential therapeutic target for mesothelioma. We found high expression levels of gremlin-1 in the mesothelioma tumor tissue, as well as in primary mesothelioma cells cultured from pleural effusion samples. Downregulation of gremlin-1 expression by siRNA-mediated silencing in a mesothelioma cell line inhibited cell proliferation. This was associated with downregulation of the transcription factor slug as well as mesenchymal proteins linked to cancer epithelial-to-mesenchymal transition. Further, resistance to paclitaxel-induced cell death was associated with high gremlin-1 and slug expression. Treatment of gremlin-1-silenced mesothelioma cells with paclitaxel or pemetrexed resulted in efficient loss of cell survival. Finally, our data suggest that concomitant upregulation of fibrillin-2 in mesothelioma provides a mechanism for extracellular localization of gremlin-1 to the tumor microenvironment. This was supported by the demonstration of interactions between gremlin-1, and fibrillin-1 and -2 peptides as well as by colocalization of gremlin-1 to fibrillin microfibrils in cells and tumor tissue samples. Our data suggest that gremlin-1 is also a potential target for overcoming drug resistance in mesothelioma.

Keywords: gremlin; fibrillin; mesothelioma; EMT; slug

INTRODUCTION

Malignant mesothelioma is an aggressive tumor, which originates from the mesothelial surface cells lining the serous body cavities such as the pleura, peritoneum or pericardium.1 Mesothelioma is strongly linked to asbestos exposure, and it may take several decades to develop after initial exposure.2 Because of the long latency, the incidence of mesothelioma will increase in the near future worldwide.3,4 Mesothelioma is resistant to chemo- and radiotherapy, leading to poor prognosis for patients suffering from this malignancy.5 New markers for screening and monitoring the disease and in particular new drug targets are needed.

Cancer progression is associated with a re-expression of developmental programs, which contribute to the proliferative and invasive properties of tumor cells.5,6 GREM1 is a cysteine knot protein, which belongs to the DAN family of bone morphogenetic protein (BMP) antagonists. GREM1 can bind to and inhibit the functions of BMP-2, -4 and -7.7,8 These three BMP isoforms are targeted to fibrillin microfibrils, suggesting extracellular regulation of bioavailability.9 GREM1-mediated BMP antagonism is crucial for mouse lung and kidney development.10 In adult mouse and human tissues GREM1 expression is low. Originally, GREM1 was identified as a gene downregulated in v-mos-transformed fibroblasts and therefore called Drm.11 However, recent studies suggest the overexpression of GREM1 in epithelial cancers including lung carcinomas.12,13

The role of GREM1 in cancer has remained largely unclear. As our preliminary results suggested an upregulation of GREM1 in mesothelioma tissue, we set out to find molecular interactions of GREM1 and study the biological function of GREM1 in mesothelioma.

RESULTS

Gremlin-1 interacts with fibrillin-1 and -2

A search for new gremlin interacting proteins was carried out using systematic affinity purification coupled with mass spectrometry identification (AP-MS). We used the well-characterized Flip-In-HEK293 cell system to produce C-terminally tagged gremlin-1 and a standardized workflow for the purification of protein complexes from cell lysates14 (Figure 1a). A low tetracycline concentration (25 ng/ml) was selected for gremlin-1 induction (Figure 1b). Immunoblotting analyses after different affinity purification steps suggested that gremlin-1 was well recovered (Figure 1c).

In order to characterize the interactome of gremlin-1, immunopurified proteins were identified using mass spectrometry. Proteins...
were first digested using trypsin and then fractionated with reverse-phase chromatography online using a mass spectrometer. The resulting peptide spectra were identified with two different search engines. A total of 12 proteins were identified to interact with gremlin-1 in three replicate experiments and with both search engines. The interaction data were filtered using a protein list (data not shown) of 377 unspecific binding proteins acquired using Flip-In HEK293 cell line transfected with the affinity tag containing plasmid. The final filtered list contained four proteins: cytokeratin-9 (Swiss-Prot: P35527), fibrillin-2 (Swiss-Prot: P35556), cytokeratin-2a (Swiss-Prot: P35908) and APOBEC1-binding protein 2 (Swiss-Prot: Q9UBS4). Fibrillin-2 was identified in all three replicate experiments and with both search engines, which improves the confidence of the identification. In addition, fibrillin-2 was identified with up to three distinct and good scoring peptides in two of the replicates further validating the interaction of fibrillin-2 and gremlin-1. Fibrilins are constituents of extracellular microfibrils and have a role in elastin assembly. They also sequester and regulate the bioavailability of growth factors such as BMP isoforms.9

In order to confirm our findings, we tested direct interactions between purified gremlin-1 and recombinant N-terminal peptides of fibrillin-1 and -2 in protein–protein interaction assays using surface plasmon resonance technology. When purified gremlin-1 (Figure 1d) was used as a ligand immobilized on the sensor chip surface and N-terminal fibrillin were flown over as analytes direct interactions with molecular affinities in the low nanomolar range (Table 1) could be measured (Figure 1e). This suggests a high

| Interaction (ligand/analyte) | $k_{on}$ (1/M*s) | $k_{off}$ (1/s) | $K_d$ (nM) |

molecular interaction between gremlin-1 and the two main building blocks of fibrillin microfibrils.

Gremlin-1 and fibrillin-2 are overexpressed in the mesothelioma tumor tissue and colocalize in vivo
To analyze whether gremlin-1 and fibrillins are coexpressed in vivo, tissue biopsies from mesothelioma patients included in this study were stained with specific antibodies. We had previously shown low levels of gremlin expression in the normal lung.16 Here, we detected low expression of gremlin in normal mesothelial cells (Figure 2a). Gremlin-1 staining was, however, detected in non-malignant, reactive mesothelial cells in control samples (pneumothorax). Intense gremlin-1 immunoreactivity was observed in all mesothelioma samples (n = 6). Fibrillin-2 immunoreactivity was shown in a strikingly similar staining pattern as observed for gremlin-1 in these tumor samples, suggesting concomitant upregulation of these developmental genes in mesothelioma. Some fibrillin-2 staining was detectable also in non-malignant reactive mesothelium. Calretinin and WT1 (Wilm’s tumor 1) are diagnostic markers for mesothelioma and were used here to identify the tumor tissue. Analyses of serial tissue sections suggested that gremlin-1 and fibrillin-2 staining localizes to calretinin-positive and -negative tumor areas (Figure 2b). Some WT-1 positivity, however, was observed in calretinin-negative areas, which represent sarcomatoid part of the tumor with more diffuse growth properties. Fibrillin-1 staining was negative in 5/6 mesothelioma and in control pleura samples. Only one mesothelioma sample showed fibrillin-1 immunoreactivity, which was specifically detected in stromal-like areas (not shown).

We analyzed colocalization of gremlin-1 with fibrillin-2 in tumor tissue using the proximity ligation assay. Intensive colocalization signals were observed for gremlin-1 and fibrillin-2 throughout the tumor tissues, suggesting that they localize to similar structures in vivo (Figure 3).

Primary human mesothelioma cells express high levels of gremlin-1 and fibrillin-2
Primary cells were cultured from mesothelioma patients’ pleural effusion samples (JP1-5). Cells were characterized by immunofluorescence staining using mesothelial markers calretinin and cytokeratin (CK)-7 as well as vimentin, which is commonly expressed by tumor cells. Majority of the cells were calretinin- and/or CK-7 positive and stained also for vimentin (Figure 4a). This suggests that the cells, which were able to proliferate, were mainly primary tumor cells. Gremlin-1 mRNA expression levels were high in these primary cells compared with Met5A cells, which are immortalized but non-tumorigenic mesothelial cells (Figure 4b). Further, the mRNA expression levels of fibrillin-1 and -2 were high in these cells (Figure 4b). The results show that primary mesothelioma cells can be cultured from pleural effusion samples and that the cells retain the phenotypic expression of these developmental genes.

Gremlin-1 is known to inhibit the functions of BMP-2, -4 and to some extent also BMP-7.7,8 Therefore, the expression levels of these BMP isoforms were analyzed in primary mesothelioma cells.

Figure 2. Overexpression of gremlin-1 and fibrillin-2 in mesothelioma. (a) Immunohistochemical staining of mesothelioma and control pleura samples using calretinin, gremlin-1, fibrillin-1 and fibrillin-2 antibodies. Hematoxylin and eosin (HE) staining is shown on the left. Abundant gremlin-1 and fibrillin-2 immunoreactivity is observed in both calretinin-negative and -positive tumor areas. Normal mesothelium (pleura, left panel) shows very low levels of staining, whereas reactive normal mesothelium (pleura, right panel) shows faint fibrillin-2 and moderate gremlin-1 staining. (b) Immunohistochemical staining of serial mesothelioma sections suggests similar staining patterns for gremlin-1 and fibrillin-2. Staining was observed also in calretinin-negative stromal-like areas, which contained isolated Wilms’ tumor protein (WT1)-positive tumor cells (white arrows).
Interestingly, abundant expression of BMP-2 was observed (Figure 4b), whereas BMP-4 levels were comparable and BMP-7 levels only slightly higher compared with Met5A cells (not shown).

The expression patterns of gremlin-1, fibrillins and BMP-2 were also analyzed in four established mesothelioma cell lines (211H, H28, H2452 and H2052). Only one of these cell lines, H2052, resembled primary mesothelioma cells and expressed high levels of gremlin-1, fibrillin-2 and BMP-2 (Figure 4c). Therefore, this cell line was chosen for further mechanistic studies.

Gremlin-1 associates with fibrillin-1 in cultured mesothelioma cells

Mesothelioma cells were cultured for 1 week and then analyzed by immunofluorescence staining using antibodies specific for gremlin-1 or fibrillins. Although expressed at the mRNA level, fibrillin-2 protein was not detected in any of the cultured mesothelioma cells analyzed at this time point (not shown), which may reflect late extracellular matrix (ECM) deposition in vitro. Primary mesothelioma cells and H2052 cells in vitro also expressed fibrillin-1 mRNA, and this was reflected in the staining pattern showing fibrillar staining for fibrillin-1 and gremlin-1 (Figure 5a). No staining was observed in H2452 cells. Double immunofluorescence labeling suggested colocalization and targeting of gremlin-1 into fibrillin-1 containing microfibrils in vitro. H2052 cells transfected with fibrillin-1-specific siRNA showed reduced mRNA expression levels (Figure 5b) and significantly reduced fibrillin-1 staining, indicating efficient silencing of protein expression (Figure 5c). This led to reduced deposition of gremlin into fibrillar structures suggesting that extracellular targeting of gremlin is dependent on fibrillins.

Gremlin-1 silencing severely impairs mesothelioma cell growth and survival

To investigate the role of gremlin-1 in mesothelioma cell growth, H2052 cells were transfected with gremlin-specific siRNAs. Efficient silencing of gremlin-1 expression was observed at mRNA and protein levels (Figures 6a and b). Cell proliferation was assayed by counting cells 1–5 days after transfection. Two independent siRNAs targeted against gremlin-1 were observed to significantly decrease the number of cells at all time points (Figure 6c). This suggests that H2052 cell proliferation is dependent on gremlin expression.

To determine whether lack of gremlin induces apoptosis, H2052 cells were cultured on coverslips, transfected with siRNAs and analyzed with TUNEL assay 3 days after transfection (Figure 6d). Hardly any TUNEL-positive cells were detected in control or gremlin siRNA-transfected cells. DAPI staining also showed intact nuclei in both groups. These results suggest that although lack of gremlin impaired cell proliferation, it did not induce apoptosis.

Cellular signaling pathway activities are altered in gremlin-1-silenced cells

Changes in BMP signaling activity were analyzed. Gremlin-1 silencing increased BMP-dependent reporter activity in H2052 cells (Figure 7a) as well as the expression of a BMP target gene Id1 (inhibitor of differentiation/DNA binding 1, Figure 7b), suggesting that endogenous gremlin-1 regulates BMP activity negatively. Further, Id1 expression was found significantly reduced in primary mesothelioma cells compared with Met5A cells (Figure 7c). To further investigate cellular signaling pathways regulated by gremlin, we analyzed alteration in phospho-kinase levels using a commercial array (see Materials and methods). H2052 cells were found to have high basal level of phospho-Akt (S473), which was not altered in gremlin-1-silenced cells (Figures 7d–f). However, phosphorylation of the Akt substrate and regulator of mTOR signaling, PRAS40 (T246), was increased. Erk1/2 phosphorylation was also significantly increased in gremlin-1-silenced cells (g). Further, increased levels of p53 phosphorylation (S53 and S392)
were reflected in increased mRNA expression levels of p21 (Cip1/Waf1) in H2052 cells (Figure 7h). In agreement, overexpression of gremlin-1 in H2052 and H28 cells decreased p21 expression levels (Figure 7i).

Gremlin-1 expression is associated with EMT phenotype and chemoresistance

Gremlin-1 expression has been linked to EMT processes. Therefore, we determined whether mesothelioma cells with high gremlin levels express transcription factors snail and slug, which are transcriptional repressors of E-cadherin and induce EMT.17 Whereas the mRNA expression levels of snail were comparable in mesothelioma cells and Met5A cells, slug expression levels were high in primary mesothelioma cells (Figure 8a). Slug expression in mesothelioma tumor samples was analyzed using immunohistochemical staining (Figures 8b and c). All of the analyzed tumor samples (n = 6) were positive for slug. Mesothelioma tumors exhibited mostly diffuse and granular cytoplasmic staining, but also nuclear staining was detected in certain tumor areas. Slug staining localized to gremlin-positive areas and was detected also in calretinin-negative areas.

Similar to primary mesothelioma cells H2052 cells, which express high levels of gremlin-1, exhibited high slug expression (Figure 8d). Conversely, Met5A and H2452 cells showed very low levels of slug mRNA expression consistent with low gremlin-1 expression levels. Slug protein levels also showed a dramatic difference between H2052 and H2452 cells (Figure 8d). Silencing of gremlin-1 by siRNA transfection significantly reduced slug mRNA and protein expressions in H2052 cells (Figure 8e and i). Similar results were also obtained with primary mesothelioma cells (Figure 8f). Further, overexpression of gremlin-1 in H28 cells led to increased slug mRNA expression (Figure 8g). The mRNA and especially protein expression levels of mesenchymal proteins, N-cadherin, vimentin and α-smooth muscle actin were significantly downregulated in gremlin-1-silenced H2052 cells (Figures 8h and i).
8h and i). Fibrillin-1 and -2 mRNA expression levels were also significantly reduced (Figure 8h), suggesting that gremlin-1 maintains the expression of microfibrillar genes. Further, fibronectin expression was downregulated (Figure 8h), and the epithelial marker E-cadherin was upregulated (Figure 8j). These results suggest that EMT-related alterations are reversed in gremlin-1-silenced cells.

Slug expression and EMT-phenotype are also associated with tumor chemoresistance.18–21 The importance of high gremlin and slug expression to sensitivity to paclitaxel-mediated mesothelioma cell death was analyzed using the MTT proliferation/viability assay. H2052 cells, which express high levels of gremlin-1 and slug, were found more resistant to paclitaxel than H2452 cells (Figure 8k). Next, control and gremlin-1 siRNA-transfected H2052 cells were treated with paclitaxel or pemetrexed, and cell numbers were quantified 3 days after transfection. Treatment with paclitaxel or pemetrexed in combination with gremlin-1 siRNA led to efficient cell death (Figure 8l).

**DISCUSSION**

Gremlin-1-mediated inhibition of BMP-signaling is important for normal development. Mice lacking gremlin-1 die before birth because of severe defects in kidney and lung development.10 In
adult tissues including lung gremlin-1 expression is low. In idiopathic pulmonary fibrosis, gremlin-1 is highly upregulated in the lung parenchyma, where it contributes to idiopathic pulmonary fibrosis pathogenesis by blocking BMP-mediated signals. Gremlin-1 has been found to be upregulated also in many carcinoma tissues as well as in mesothelioma. The role of gremlin-1 in malignant tissue appears complex and is likely mediated both by BMP-dependent and -independent functions. There are reports suggesting tumor-specific gremlin-1 expression, while other reports suggest expression in cancer-associated stromal cells. Here, we find high gremlin immunoreactivity in the mesothelioma tumor tissue. Analyses of serial mesothelioma tissue sections suggested that gremlin-1 can localize to calretinin-positive, epithelial-appearing tumor areas and also to aberrant looking and stromal-like calretinin-negative areas. These tissue areas contained some WT1-positive tumor cells.

Figure 6. Gremlin-1 silencing impairs H2052 mesothelioma cell proliferation. (a) The efficiency of gremlin-1 siRNA silencing was analyzed with quantitative RT-PCR as in figure 5. The error bars represent s.d. (n = 4). (b) Double immunofluorescence staining of siRNA-treated H2052 cells with gremlin-1 and fibrillin-1 antibodies. Note the lack of fibrillar gremlin-1 staining, which is suggestive of efficient silencing using gremlin siRNA3. (c) H2052 cell proliferation was analyzed by counting cells 1–5 days after siRNA transfection. Both gremlin siRNAs reduced dramatically the number of cells 3–5 days after transfection (left panel, a representative experiment is shown). Same effect was seen also at earlier time points (right panel). The error bars represent s.d. (n = 3, *P = 0.05). (d) Silencing gremlin-1 by siRNA3 did not induce apoptosis as measured using TUNEL staining. DNase I-treated cells (control) show positive staining. Nuclei are stained with DAPI.
Our results suggest that gremlin-1 localizes mainly in and around mesothelioma tumor cells. Using a sophisticated large-scale protein interaction screen, we were able to identify fibrillin-2 as a novel gremlin-1 interacting protein. The interaction was also verified using a cell surface plasmon resonance technology.

Fibrillin-2 is a developmental gene, which is found in adult vasculature and is upregulated in idiopathic pulmonary fibrosis, scleroderma and during skin wound healing. Idiopathic pulmonary fibrosis and cancer pathogenesis have common features including aberrant activation of mediators of tissue repair processes. Our discovery that high fibrillin-2 immunoreactivity is associated with mesothelioma tumor tissue is a novel finding and supports this idea. Fibrillins (fibrillin-1 and -2) are large extracellular glycoproteins, which form heteromeric fibrillar structures, the so-called fibrillin microfibrils, which are essential for elastin assembly. Fibrillins also regulate growth factor signaling by sequestering TGF-β complexes as well as BMP-sisfoms into extracellular matrix structures. Gremlin-1 can bind to and inhibit the functions of BMP-2, -4 and -7, all of which have been shown to associate with fibrillins. Here, we find that gremlin-1 can bind to fibrillin-1 and -2 in vitro and colocalizes with fibrillin-2 in mesothelioma tumor tissue in vivo. Conceptually this is a new finding, spatially localizing a BMP inhibitor molecule with its target proteins through fibrillin microfibrils. High levels of fibrillin-2 are likely to contribute to tumor cell behavior through aberrant extracellular matrix structure and regulation of gremlin-1 function.

Primary mesothelioma cells were cultured from patients’ pleural effusion samples and analyzed after few passages of culture. Immunofluorescence microscopy analyses indicated that the cells, which were able to grow, represented mostly tumor cells. Gremlin-1 was expressed at mRNA and protein levels and fibrillin-2 at mRNA level by these primary cells, suggesting that they retain the pathological expression pattern of these genes. Interestingly, fibrillin-1 but not fibrillin-2 protein was detected in the matrix structures after 1 week culture of the primary cells. This likely reflects the temporal production of ECM proteins and remodeling of matrix structures during in vitro cell cultures. Fibrillin-2 is likely assembled late during this process. In agreement with the protein interaction studies, gremlin-1 localized to fibrillin-1-
Figure 8. Gremlin-1 regulates slug expression and EMT phenotype. (a) Primary human mesothelioma cells (JP) were analyzed for snail and slug mRNA expression by quantitative RT-PCR. The levels were normalized to the expression levels of TATA-binding protein and are expressed relative to the expression levels in Met5A cells, which were set to 1. (b, c) Immunohistochemical staining of a mesothelioma section using slug antibodies shows mostly diffuse and granular cytoplasmic staining in the tumor tissue. Nuclear staining was also observed in certain tumor areas (b, right panel). (c) Analyses of serial mesothelioma tissue sections suggested that slug and gremlin staining colocalized in the same tumor areas. (d) Slug mRNA expression levels in H2052 and H2452 cells were analyzed by quantitative RT–PCR. The levels are expressed relative to H2452 expression levels, which were set to 1. The error bars represent s.d. (n = 5). INSET: immunoblotting analyses of slug. Tubulin is used as a loading control. (e–g) Slug mRNA expression levels were analyzed in control and gremlin-1 siRNA-treated H2052 and JP5 cells or H28 cells transfected with gremlin-1 (grem1) or control vector (mock). The levels are expressed relative to control, which was set to 1. The error bars represent s.d. (JP5, n = 3, *P < 0.05; H2052, n = 4, *P < 0.01; H28, n = 3, *P = < 0.05). (h) N-cadherin, vimentin, α-SMA, fibronection and fibrillin mRNA expression levels were analyzed in control and gremlin siRNA-treated H2052 cells by quantitative RT-PCR. The error bars represent s.d. (n ≥ 3, *P < 0.05). (i) Immunoblotting analyses of slug, N-cadherin, vimentin and α-SMA in control and gremlin-1 siRNA-treated H2052 cells. Tubulin is used as a loading control. (j) E-cadherin mRNA expression levels were analyzed in control and gremlin siRNA-treated H2052 cells by quantitative RT–PCR. Error bars represent s.d. (n = 3, *P < 0.05). (k) H2052 and H2452 cells were treated with the indicated concentrations of paclitaxel after which cell proliferation/viability was analyzed with MTT assay (n = 4, *P < 0.05). (l) Quantification of cell numbers after combined treatment with control or gremlin-1 siRNA and paclitaxel (0.1 nM, 24 h) or pemetrexed (1 μM, 48 h). Cell numbers were counted 3 days after transfection (n ≥ 4, *P = 0.002).
Gremlin-1 has been shown to bind directly to a 14-3-3 protein,12 phosphorylation and expression of its target gene, cell was found to reduce proliferation. We observed increased p53 proliferation of epithelial cells through blocking BMP activities.13,36 to mesenchymal cells surrounding stem cell niches, which support malignant mesothelial cells. Gremlin-1 expression has been linked to mesenchymal transition (EMT) in mesothelioma cells. EMT is mediated by induction of the transcription factor slug and leads to chemoresistance and acquisition of invasive properties. Gremlin-1 is targeted to the tumor microenvironment through binding to fibrillin-2 microfibrils.

We used the knowledge of gene expression patterns of primary mesothelioma cells to find a representative established mesothelioma cell line for mechanistic studies. H2052 cells expressed high levels of gremlin-1, fibrillin-2 and BMP-2 similar to all of the primary cells. Gremlin-1 silencing in these cells reduced cell proliferation dramatically. This is in agreement with previous studies suggesting that gremlin-1 can induce proliferation of cancer cells.33–35 Interestingly, we observed gremlin-1 immunoreactivity also in reactive mesothelium, which associates gremlin-1 expression to a proliferative phenotype even in non-malignant mesothelial cells. Gremlin-1 expression has been linked to mesenchymal cells surrounding stem cell niches, which support proliferation of epithelial cells through blocking BMP activities.19,36 Mesenchymal stem cells also express high levels of gremlin-1 (GeneSapiens database37). Our data suggest a model in which cancer cells can acquire the ability to produce high levels of gremlin-1, which is targeted to the tumor microenvironment through fibrillin binding (see Figure 9).

Signaling pathways linked to the regulation of cell survival, apoptosis and autophagy were altered in gremlin-1-silenced H2052 cells. Similar to our findings, negative regulation of Erk1/2 phosphorylation by gremlin-1 has been previously found in osteosarcoma cells.38 However, gremlin overexpression in Saos-2 cell was found to reduce proliferation. We observed increased p53 phosphorylation and expression of its target gene, p21, in gremlin-1-silenced cells, suggesting a link to reduced cell survival. Further, the phosphorylation of the Akt substrate PRAS40 was significantly increased. Although PRAS40 has been linked to diabetes and cancer, its pathological functions are not well understood.39 Interestingly, gremlin-1 has been shown to bind directly to a 14-3-3 protein,12 which in turn binds and regulates the PRAS40 and other Akt/mTOR pathway proteins. Future studies will reveal the mechanistic details how cellular and secreted gremlin-1 regulates these pathways.

We and others have previously linked gremlin-1 expression to EMT processes.16,40,41 In cancer cells, markers of EMT often suggest more advanced disease, invasive capacity and chemoresistance.21,42 We found that the transcription factor slug, a master regulator of EMT, was upregulated in mesothelioma cells concurrently with gremlin-1. Silencing of gremlin-1 expression led to reduced slug mRNA and protein levels. Further, mesenchymal markers of EMT, vimentin, α-smooth muscle actin, fibronectin and N-cadherin were downregulated in gremlin-1-silenced cells, whereas epithelial marker E-cadherin was upregulated. These results are in agreement with previous studies linking the expression of EMT-related transcription factors to mesothelioma43,44 and provide evidence that gremlin functions as a regulator of these transitional processes. EMT and slug expression have also been suggested to be involved in regulating cancer stemness as well as chemoresistance.18,20,42 In agreement, we observed that high gremlin-1 and slug expressions in mesothelioma cells were associated with reduced sensitivity to paclitaxel-mediated cell death. Combined treatment with paclitaxel and gremlin-1 siRNA led to efficient cell death in vitro. Similar results were obtained with pemetrexed, which is a relatively new cancer drug used in the treatment of mesothelioma in combination with platinum compounds.45 This indicates that blocking gremlin-1 function may be beneficial in mesothelioma especially when combined with chemotherapy.

Mesothelioma is an aggressive tumor with limited treatment options. Further, an increase is expected in the incidence of mesothelioma,4,3 which sets an urgent need for new drug target molecules. Although the number of patient tissues analyzed in our study was relatively small (n = 6), the pathological expression of gremlin-1 was a clear concept. It is also reinforced by other studies suggesting a role for gremlin-1 in cancer cell proliferation.12,13,33,34 Gremlin-1 has also BMP-independent angiogenic functions,46 which may well contribute to tumor progression. Blocking gremlin-1 function in mesothelioma might offer means to fight the chemoresistance of this tumor.

Figure 9. A model for the functions of gremlin-1 and fibrillin-2 in mesothelioma. Gremlin-1 induces proliferation and epithelial-to-mesenchymal transition (EMT) in mesothelioma cells. EMT is mediated by induction of the transcription factor slug and leads to chemoresistance and acquisition of invasive properties. Gremlin-1 is targeted to the tumor microenvironment through binding to fibrillin-2 microfibrils.
MATERIALS AND METHODS

Antibodies

Antibodies used in the study are summarized in Table 2.

Patients and tissues specimen

A statement for the use of human tissue and pleural effusion materials was received from the Ethics Committee of the Helsinki University Hospital, Helsinki, Finland (number 308/13/0301/2010). All patients gave informed consent to participate in the study. Tissue biopsies and pleural effusion samples were obtained from patients undergoing diagnostic procedures and had a clinical and/or radiological suspicion of malignant mesothelioma. All patients included in the study (n = 7) were later diagnosed to have mesothelioma (Table 3). Control pleural samples were obtained from two male smokers who were operated for pneumothorax.

Cell culture and transient transfection

Immortalized normal mesothelial cells (Met5A), and mesothelioma cell lines (211H, H28, H2452 and H2052) were from ATCC. Primary mesothelioma cells (named JP cells) were acquired from pleural effusion samples obtained for cell culture (cells) are indicated. Tissues analyzed by immunohistochemistry (IHC) and pleural effusion samples obtained for cell culture (cells) are indicated.

Expression constructs and stable transfection

C-terminal gremlin-1 construct was generated by Gateway-cloning, the gremlin-1 construct from the Human Orfeome Collection (Thermo Scientific, FL, USA) to a pTo-ScH-GW-FRT plasmid with c-terminal Strep-tag III and human influenza hemagglutinin (HA)-tag. Flip-In human embryonic kidney (HEK) 293 cells (Life Technologies) were grown as described. The BMP reporter construct (Bre2-luc, kindly provided by Dr Peter ten Dijke, Leiden University, The Netherlands) was transfected into H2052 cells to assess BMP-dependent signaling activity as described.

Affinity purification

Transfected Flip-In HEK293 cells were stimulated with tetracycline (25 ng/ml) to induce gremlin-1 expression. After a 24-h stimulation, cells were lysed in HNN-lysis buffer (50 mM HEPES pH 8, 150 mM NaCl, 50 mM NaF, 1 mM PMSF, 1.5 mM Na-vanadate, 0.5% NP-40 and protease inhibitors (Sigma)) followed by double affinity purification as described. Briefly, cell lysates were passed through Strep-Tactin columns (IBA GmbH) followed by elution of bound proteins with 50 mM ammonium bicarbonate, pH 8.9, containing 0.1% Rapigest detergent (Waters, Milford, MA, USA). Proteins were reduced using DTT for 30 min at room temperature in dark. Proteins were digested with trypsin (Promega, Madison, WI, USA) for 18 h at 37 °C, and then the Rapigest detergent was hydrolyzed with HCl for 45 min at 37 °C. Peptides were purified with PepClean C18 Spin Columns (Thermo Fisher, Rockford, IL, USA) according to the manufacturer’s protocol. Finally, the purified peptides were dissolved in 0.1% formic acid for MS analysis.

Protein digestion

The total protein amount from the elution fractions was precipitated using trichloroacetic acid (TCA). First, TCA was added to the elution fractions to final concentration of 25% followed by incubation for 30 min on ice. The precipitates were centrifuged, washed once with ice cold 0.1 M HCl in acetone and once with acetone. The pellets were then allowed to dry. For trypsin digestion the precipitated proteins were dissolved in 50 mM ammonium bicarbonate, pH 8.9, containing 0.1% Rapigest detergent (Waters, Milford, MA, USA). Proteins were reduced using DTT for 30 min at 60 °C followed by alkylation using iodoacetamide for 30 min at room temperature in dark. Proteins were digested with trypsin (Promega, Madison, WI, USA) for 18 h at 37 °C, and then the Rapigest detergent was hydrolyzed with HCl for 45 min at 37 °C. Peptides were purified with PepClean C18 Spin Columns (Thermo Fisher, Rockford, IL, USA) according to the manufacturer’s protocol. Finally, the purified peptides were dissolved in 0.1% formic acid for MS analysis.

Table 3. Mesothelioma patient characteristics

| Patient | Type   | Location | Age | Gender | IHC | Cells |
|---------|--------|----------|-----|--------|-----|-------|
| JP1     | Epithelial | Pleura  | 53  | Male   | +   | +     |
| JP2     | Biphasic | Pleura  | 71  | Male   | +   | -     |
| JP3     | Epithelial | Pleura  | 63  | Male   | +   | +     |
| JP4     | Biphasic | Peritoneum | 72  | Female | -   | +     |
| JP5     | Epithelial | Pleura  | 69  | Female | +   | +     |
| JP6     | Biphasic | Pleura  | 71  | Female | +   | -     |
| JP7     | Epithelial | Pleura  | 61  | Male   | +   | -     |

Tissues analyzed by immunohistochemistry (IHC) and pleural effusion samples obtained for cell culture (cells) are indicated.

Table 2. List of antibodies used in the study

| Name           | Source          | Application | Supplier |
|----------------|-----------------|-------------|----------|
| calretinin     | mouse/DAK-Calret1 | IF, IHC     | DAKO, Glostrup, Denmark, Germany |
| cytokeratin-7  | rabbit/EP16204  | IF          | Novus Biologicals, Littleton, CO, USA |
| vimentin       | mouse/V9        | IF, IB      | Santa Cruz, Santa Cruz, CA, USA |
| N-cadherin     | mouse/32        | IB          | BD Biosciences, Franklin Lakes, NJ, USA |
| z-SMA          | mouse/1A4       | IB          | Sigma, St Louis, MO, USA |
| HA             | mouse/16812     | IB          | Covance, Princeton, NJ, USA |
| fibrillin-1    | mouse/2499      | IB          | Millipore, Billerica, MA, USA |
| fibrillin-1    | rabbit/pAb9543  | IHC, IF     | Professor Lynn Sakai |
| fibrillin-2    | mouse/48        | IHC, PLA    | Millipore |
| gremlin-1      | rabbit pAb      | IHC         | Abcam, Cambridge, UK |
| gremlin-1      | goat pAb        | IHC, PLA    | Santa Cruz |
| gremlin-1      | rabbit pAb      | IF          | Santa Cruz |
| Slug           | rabbit pAb      | IB          | Sigma |
| WT1            | mouse/WT49      | IHC         | Novocastora, Newcastle, UK |
| p-Akt (S473)   | rabbit pAb      | IB          | Cell Signaling, Danvers, MA, USA |
| p-Akt (T308)   | rabbit pAb      | IB          | Cell Signaling |
| p-Erk1/2       | rabbit mAb/D13.14.4E | IB     | Cell Signaling |
| Erk1           | mouse/3A7       | IB          | Cell Signaling |
| V5             | Mouse mAb       | IB          | Invitrogen |

Abbreviations: IB, immunoblotting; IF, immunofluorescence; IHC, immunohistochemistry; PLA, proximity ligation assay.
LC-MS/MS analysis
Mass spectrometric analysis was performed using nanoAcquity UPLC – liquid chromatography system on-line with a Waters Synapt G2 mass spectrometer (Waters S.A.S., Saint-Quentin, France). Waters nanoAcquity UPLC Trap Column (Symmetry C18, 180 μm × 20 mm, 5 μm) was used as trapping and Waters nanoAcquity UPLC Column (BEH130 C18, 75 μm × 150 mm, 1.7 μm) as analytical column. Four microliters of sample was injected and run using 90 min gradient from 3 to 40% mobile phase B (0.1% formic acid in acetonitrile). 0.1% formic acid in water was used as mobile phase A.

Data were collected with data dependent acquisition manner collecting eight fragmentation spectra simultaneously. Switch limit from MS to MS/ MS was set to peak intensity of 200. Fragmentation data for detected peaks were collected for 5 s and then excluded from fragmentation for 120 s. Scan time for both MS and MS/MS was one second. No lock mass correction was used.

The raw data were processed with Mascot Distiller software (version 2.3.1.0, Matrix Science, London, UK), and database search was performed using Mascot search engine (version 2.2.04) against Swiss-Prot human database (dated 16.6.2010). MuddPIT scoring and ion score cutoff limit of 20 were used to identify peptides. Require bold red specification was used to limit the results to those proteins that have at least one unique peptide. Carbamylated peptide list was set as fixed modification and oxidation of methionine as variable modification. Peptide mass tolerance for search was 0.2 Da and 0.1 Da for fragment ion search. A maximum of two missed tryptic cleavages was allowed. The Mascot Distiller processed data were also searched using GPM X!Tandem search engine53 using same parameters.

Expression and purification of recombinant gremlin-1
The expression construct pGremlin-1/V5/HIS in pEF-IRESP contains cDNA encoding human gremlin-1 with C-terminal tags (V5 and 6HIS). H2052 and H28 cells were transiently transfected with this construct or the expression vector using Fugene HD transfection reagent (Promega). CHO cells were stably transfected, and gremlin-containing cell culture supernatants were produced as described.54 The media was then dialyzed against 0.2 M sodium phosphate buffer, pH 7.2 and 1 M NaCl (buffer A) and loaded on a 1-ml HiTrap heparin column (GEHC) (BIAevaluation 4.1 software). Bound gremlin-1 was eluted in a 0–1 M EDTA, 1% NP-40, 0.2% sodium deoxycholate gradient run starting with buffer A and run using 90 min gradient from 3 to 40% mobile phase B (0.1% formic acid in acetonitrile). The loaded column was washed with 40 column volumes of buffer A and subjected to a fast protein liquid chromatography (GEHC) gradient run starting with buffer A containing 0–100% buffer B (buffer A with 250 mM imidazole). Fractions containing 0–100% buffer B (buffer A with 250 mM imidazole). Fractions were analyzed using SDS–PAGE for their purity and molecular mass, and imidazole in these fractions was removed by dialysis against buffer A. For further concentration and purification, gremlin-1-containing fractions were dialyzed against TBS and subjected to affinity chromatography using a 1-ml HiTrap heparin column (GEHC). Bound gremlin-1 was eluted in a 0-1 M NaCl gradient.

Surface plasmon resonance
Binding analyses were performed using a BIAcore2000 (GEHC). 2000 RU of gremlin-1 were covalently coupled to carboxymethylidextran hydrogel 500 μm sensor chips (XanTec, Düsseldorf, Germany) using the amine coupling kit following the manufacturer’s instructions (GEHC). Binding assays with N-terminal fibrillin-1 (f11) and -2 peptides (f26) as analytes were performed as previously described.5 Kinetic constants were calculated by non linear fitting of association and dissociation curves (BIAevaluation 4.1 software).

Immunohistochemical staining and proximity ligation assay
Immunohistochemical staining of tumor tissues and proximity ligation assay were performed as described.24 Images were captured with Nikon DS-Fil or with Axio Image with ApoTome (Zeiss, Göttingen, Germany) or with using Axio Vison 4.8 software (Zeiss).

SDS–PAGE and immunoblotting
Cells were lysed in RIPA lysis buffer (50 μl Tris-HCl, pH 7.4, 150 μl NaCl, 1 ml EDTA, 1% NP-40, 0.2% sodium deoxycholate) containing protease inhibitors (Roche, Mannheim, Germany) for 15 min on ice. Protein concentrations were measured using a BCA protein assay Kit (Pierce, Rockford, IL, USA). SDS–PAGE and immunoblotting were performed as described.53

RNA isolation and gene expression analyses
Isolation of total cellular RNA, reverse transcription and quantitative real-time PCR were carried out as described.54 The relative gene expression differences were calculated with the comparative delta delta cycle threshold (ΔΔCT) method, and the results have been expressed as mRNA expression levels normalized to the levels of a gene with a constant expression (TATA-binding protein).

Immunofluorescence analyses and microscopy
Cells were grown on glass coverslips for the indicated times and fixed with 4% paraformaldehyde in PBS at room temperature for 10 min or with ice cold methanol at −20 °C for 20 min. Immunofluorescence staining was carried out as described.53 Images were captured with a Axioplan 2 epifluorescence microscope (Zeiss) and AxioCam HRM 14-bit grayscale CCD camera Axiovision 4.6 software (Zeiss).

Human phospho-kinase array
Control and gremlin-1 siRNA-treated cells were lysed, and alterations in phospho-kinase levels were analyzed using a Proteome profiler array (ARY003b, R&D Systems, Gaithersburg, MD, USA) according to the manufacturer's instructions. Quantity One version 4.6 (Biorad, Hercules, CA, USA) was used for quantification. The Kinase array was performed twice, and the results are expressed as average of the two experiments.

Measurements of cell viability and apoptosis
Cell proliferation/viability was assessed using MTT assay (R&D Systems). Briefly, cells were seeded on 96-well plates (10 000/well) and were treated the next day with different concentrations of paclitaxel (Hospira, Lake Forest, IL, USA). The metabolic activity of cells was measured after 48 h according to the manufacturer's instructions. Apoptosis was assayed using a TUNEL technology using in Situ cell death detection kit (Roche). Cells were seeded on glass coverslips, cultured overnight and transfected with siRNAs. Cells were then fixed and stained, according to the manufacturer's instructions, 3 days after transfection.

Statistical analyses
Data were analyzed using PASW Statistics 18 program for Windows (SPSS, Chicago, IL, USA). Statistical difference between two independent groups was evaluated using nonparametric Mann–Whitney U-test. Statistical difference between more than two independent groups was evaluated using nonparametric Kruskal–Wallis test. A P-value of <0.05 was considered statistically significant.

CONFLICT OF INTEREST
The authors declare no conflict of interest.

ACKNOWLEDGEMENTS
We thank Eva Sutinen for coordinating patient sample collection and performing immunohistochemical staining experiments, Arja Parternack for CHO cell transfection and production of conditioned media, Sami Starast for technical assistance, Professor Jorma Keski-Oja for discussions, Professor Lynn Sakai (Oregon Health and Science University, Portland, OR) for the fibrillin-1 antibody and fibrillin-1 and -2 peptides, and Biomedicum Imaging Unit for imaging support. This work was supported by Academy of Finland, Sigrid Jusélius Foundation, Jalmarini and Rauha Aho Foundation, Magnus Ehrnrooth Foundation, Finnish Cultural Foundation, Foundation of the Finnish Anti-Tuberculosis Association, Deutsche Forschungsgemeinschaft (SF8829, project B12 to GS).
