Femoral neck fractures in adults have a poor prognosis because of high incidence of non-union and aseptic necrosis. Prosthetic replacement of the femoral head is reserved for the physiologically older patients while osteosynthesis with preservation of femoral head is the treatment of choice for fracture neck femur in younger adults. Various types of bone graft supplementation have been advocated to reduce the incidence of nonunion and avascular necrosis. Thirty-five (M:18: F:17) skeletally mature patients (mean age 49.38 years) of fresh femoral neck fracture were treated. Weight bearing was allowed only after 3 months, or later if the radiological signs of union was not seen. All fractures showed union at one year follow up. Complications included, avascular necrosis (2 cases), broken fibular graft (3 cases), screw back out with collapse (2 cases), penetration of the femoral head articular surface by screw and graft (1 case each). Patients are able to sit cross-legged and squatting position. Cancellous screw fixation and fibular autografting is a safe, cost effective and reliable surgical technique for treating femoral neck fractures in properly selected patients.

Long Term Year Results of Fresh Femoral Neck Fractures Treated by Cancellous Screw and Fibular Autograft

The prepared fibular diaphyseal graft was gently tapped in the graft-bed. The wound was closed in layers. Post-operative mobilization in bed, isometric quadriceps exercises and knee bending was encouraged from the second post-operative day. Non-weight bearing crutch walking was allowed at 6 weeks. Weight bearing was permitted only after union, which took about 3 months. The patients were followed up at regular interval of three months till one year and then at six monthly intervals for next 2 years. Finally after further 5 years i.e. a total of 8 year follows up. Clinical assessment included pain, hip joint movement, limb length discrepancy and stability of hip. Treatment outcome was assessed using Harris hip score, for which the maximum score is 100, which included pain (44 points), function (47 points) and deformity (4 points).

Results

Thirty-one patients completed a follow-up of 3 years (mean 32.7 months). At 8 year follow up only 24 patients responded, 6 patients had migrated to another location with no forwarding address and one patient died with causes unrelated to fracture. Union

All patients showed union by year end. Thirty of 35 patients (85.7%) showed union by the end of 6 months, 4 fractures united by 9 months and one fracture united by year end.

Avascular necrosis

Only two cases showed asymptomatic avascular necrosis (AVN) of head. The first case was 40 years old and he developed signs of AVN after two and half year of fixation, but he was asymptomatic. The second patient, 50 years old, showed changes of AVN on radiographs after one and half year after surgery. This patient does have pain but refused a second surgery. He needs oral analgesics 4-5 days in a month. Both are community ambulators and are back to their previous level of social function.

Penetration of femoral head

Penetration of the articular cartilage by screw (long screw) and by fibular graft (long graft) was observed in post-operative radiographs in one case each. The screw was withdrawn by 5mm in a second surgery done under local anesthesia.

Pain in hip joint

Ten patients have pain on long distance walking and 6 patients have slight limp while walking.

Functional results

Functional range of movements was achieved in all cases. All patients are able to sit cross-legged and squat. (Figure 1 & 2).

Other complications were- broken fibular graft, coxa vara and leg length discrepancy. Fibular graft was broken and loss of reduction was seen in 3 cases, two of which had the fracture fixed by only one screw and in these cases there was a second trauma. One of them (60 year male) had to jump from a cycle rickshaw in order to avoid being hit by another vehicle. The second (28 year female) had been hit by a pedal-cyclist. The third (60 year female) started bearing full weight after 6 weeks only. Bipolar arthroplasty was done in two cases and McMurray’s osteotomy was done in one case. Screw back out with settling of the fracture was seen in 2 cases. Shortening of less than 2 cm was seen in 4 cases. No superficial or deep infections were seen.

Discussion

Femoral neck fractures occur commonly in elderly patients and usually due to minor trauma. But when this fracture occurs in relatively younger patients the amount of trauma is usually much more. In the treatment algorithm of femoral neck fracture, the patients who are less than sixty-five years old and do not have any chronic medical illnesses should be managed with immediate reduction and internal fixation of the fracture with 6.5 mm cancellous screws with the aim of preserving patients own natural hip[3,21-22]. The incidence of nonunion and avascular necrosis is much higher in younger patients, probably because of much more soft tissue injury and vascular insult occurring due to greater amount of trauma [23-24].

Cancellous screws have been preferred over DHS implant assembly for internal fixation in younger patients with good bone.
stock, while DHS or angled blade-plate with additional screw has been preferred in patients with osteoporotic bone [25-28].

Why a graft?

Bone grafts procedure has been supplemented along with internal fixation in cases where the treatment was delayed due to some reason or the patients had ununited fractures at the time of presentation for treatment [7-9,13,23,29]. Primary autologous fibular grafting along with cancellous screw fixation in fresh cases has been done and good results have been reported by two workers [13,15]. In this study we have used fibular autograft in all our patients. Since being young, they do not have the option of replacement of femoral head. Hence, we believe that maximum and best have to be done at the first opportunity to save the patient's own biological femoral head by augmenting with bone graft.

Choice of graft

Various types of bone grafting procedures ranging from pheinstein graft, nonvascularised (iliac crest graft, fibular graft), vascularized muscle pedicle (Quadratus femoris, Sartorius, Guteus medius) based grafts have been used in the treatment of femoral neck fractures but no single technique have shown superiority of one technique over other techniques in a randomized controlled trial. We chose autologous ipsilateral fibular graft as the procedure can be easily done at simpler setups across the developing world. Moreover, it being cortical and tubular would not only provide mechanical strength like a screw in maintaining the reduction but also provide osteogenic stimulus across the fracture site. Multiple drill holes in the grafts also encourage the in growth of the creeping substitution. Hence, fibular graft acts as a “biodegradable graft-implant”. Dual fibular grafting with or without cancellous screw has been done for neglected fracture neck of femur in adult patients and excellent to fair results have been reported by many [12,20]. The authors believed that use of double fibular strut graft acts as double Smith Peterson nail because of the trephine shape of fibula. This provides enough mechanical stability till fracture union.

Muscle pedicle bone grafting and vascularized fibular grafting are probably superior technique but are skill dependent, time consuming, expensive and require microsurgical sophisticated equipments which are not readily available at most of the tertiary level hospitals in India.

Fate of fibular graft

The fate of the graft has not been studied and reported as yet, but it is believed that it gets incorporated with the host bone rather than getting resolved. The fibular graft starts fusing with the host bone and is seen as gradual decrease in the density of the graft and loss of cortical details of the graft. In this series there were two cases where fibular graft was broken and subsequent replacement arthroplasty was done. In these cases, on gross examination of the cut section of removed femoral head did show that the fibula was getting fused with the host bone. The exact time frame of the graft incorporation has not been studied by any worker. We believe that autologous fibular graft strut graft should be used as an adjuvant to anatomic reduction and internal fixation in all fresh femoral neck fractures primarily, especially in younger adults, as this provides a more osteogenic environment for fracture healing without jeopardizing the already precarious blood supply to the femoral head.

Randomized controlled trials comparing all alternatives with sufficiently long follow ups will be able to provide ultimate answers to this vexed question choice of grafting in fresh femoral neck fractures, but this case series does prove its durability, safety and affectivity in simple settings.

Conclusion

We conclude that fresh femoral neck fractures can be safely treated by closed/open reduction cancellous screw fixation supplemented primarily by fibular graft. The results are quite encouraging if the anatomical or slight valgus reduction is achieved and strict adherence to the post-operative rehabilitation schedule is followed.
