The Lyapunov dimension and its computation for self-excited and hidden attractors in the Glukhovsky-Dolzhansky fluid convection model

Kuznetsov N. V., Leonov G. A., Mokaev T. N.

Abstract

Consideration of various hydrodynamic phenomena involves the study of the Navier-Stokes (N-S) equations, what is hard enough for analytical and numerical investigations since already in three-dimensional (3D) case it is a challenging task to study the limit behavior of N-S solutions. The low-order models (LOMs) derived from the initial N-S equations by Galerkin method allow one to overcome difficulties in studying the limit behavior and existence of attractors. Among the simple LOMs with chaotic attractors there are famous Lorenz system, which is an approximate model of two-dimensional convective flow and Glukhovsky-Dolzhansky model, which describes a convective process in three-dimensional rotating fluid and can be considered as an approximate model of the World Ocean. One of the widely used dimensional characteristics of attractors is the Lyapunov dimension. In the study we follow a rigorous approach for the definition of the Lyapunov dimension and justification of its computation by the Kaplan-Yorke formula, without using statistical physics assumptions. The exact Lyapunov dimension formula for the global attractors is obtained and peculiarities of the Lyapunov dimension estimation for self-excited and hidden attractors are discussed. A tutorial on numerical estimation of the Lyapunov dimension on the example of the Glukhovsky-Dolzhansky model is presented.

Keywords: chaos, self-excited and hidden attractors, Lorenz-like systems, finite-time Lyapunov exponents, Lyapunov characteristic exponents, exact Lyapunov dimension formula, tutorial on numerical estimation, Kaplan-Yorke formula

1. Introduction

The main difficulties in studying fluid motion are related to infinite number of degrees of freedom of hydrodynamic objects. To overcome these difficulties, one may use an approximation (e.g., applying Galerkin method [1]) of system of equations, describing the considered object with an infinite number of degrees of freedom, by a system of equations with a finite number of degrees of freedom. Resulting finite-dimensional analogues of the hydrodynamic equations, called low-order models, turn out to be more convenient for analytical and numerical investigations [2–4]. Among the famous physically sounded low-order models there are the Lorenz model [5] (describing the Rayleigh-Bénard convection), the Vallis model [6] (describing El Niño climate phenomenon), and the Glukhovsky-Dolzhansky model [7] (describing fluid convection inside the rotating ellipsoidal cavity under the horizontal heating). One of the substantial features of these models is the existence of chaotic attractors in their phase spaces. From both theoretical and practical perspective it is important to localize these attractors [8, 9], study their basins of attraction [10–12], and estimate their dimensions [13] with respect to varying parameters.

In the present paper a three-dimensional model, describing the convection of fluid within an ellipsoidal rotating cavity under an external horizontal heating, is considered. This model was suggested by Glukhovsky and Dolghansky [7] (G-D) and can be considered as an approximate model of the World Ocean. The mathematical G-D model is described by the following system of ODEs:

\[
\begin{align*}
\dot{x} &= -\sigma x + z + a_0 y z, \\
\dot{y} &= R - y - x z, \\
\dot{z} &= -z + xy,
\end{align*}
\]

(1)

where \( \sigma, R, a_0 \) are positive parameters.

After the change of variables:

\[
(x, y, z) \rightarrow \left( x, R - \frac{\sigma}{a_0 R + 1} z, \frac{\sigma}{a_0 R + 1} y \right),
\]

(2)
system (1) takes the form of generalized Lorenz system

\[ \begin{align*}
\dot{x} &= -\sigma x + \sigma y - Ayz, \\
\dot{y} &= rx - y - xz, \\
\dot{z} &= -bz + xy,
\end{align*} \tag{3} \]

where

\[ b = 1, \quad A = \frac{a_0\sigma^2}{(a_0R + 1)^2}, \quad r = \frac{R}{\sigma}(a_0R + 1). \tag{4} \]

If

\[ R = r(\sigma - Ar) > 0, \quad a_0 = \frac{A}{(\sigma - Ar)^2} > 0, \quad b = 1. \tag{5} \]

then we have the inverse transformation

\[ (x, y, z) \rightarrow \left( x, \frac{1}{\sigma - Ar} z, r - \frac{1}{\sigma - Ar} y \right). \]

For \( A = 0 \) system (3) coincides with the classical Lorenz system \([5]\). System (3) with the parameters \( r, \sigma, b > 0 \) is mentioned first in the work of Rabinovich \([14]\) and in the case \( A < 0 \) can be transformed \([15]\) to the Rabinovich system of waves interaction in plasma \([16, 17]\). Following Glukhovsky and Dolghansky \([7]\), consider system (3) under the physically sounded assumption that \( r, \sigma, b, A \) are positive.

![Figure 1: Self-excited and hidden attractors in system (3) with \( b = 1, \sigma = 4, A = 0.0052 \).](image)

(a) Monostability \((r = 687.5)\): trajectories from almost all initial points except for a set of zero measure (including unstable equilibria \( S_{0,1,2} \)) tend to the same chaotic attractor \( K_{\text{self-excited}} \) (self-excited attractor with respect to all three equilibria: e.g., one-dimensional unstable manifold of \( S_0 \) is attracted to \( K_{\text{self-excited}} \) and, thus, visualizes it).

(b) Multistability \((r = 700)\): Coexistence of three local attractors — two stable equilibria \( S_{1,2} \) and one chaotic attractor \( K_{\text{hidden}} \) (hidden attractor, which basin of attraction does not overlap with an arbitrarily small vicinity of equilibria: one-dimensional unstable manifold of \( S_0 \) is attracted to \( S_{1,2} \)).

Figure 1: Self-excited and hidden attractors in system (3) with \( b = 1, \sigma = 4, A = 0.0052 \).

Systems (1) and (3) are of particular interest because they have chaotic attractors (Fig. 1). By numerical simulations in the case when parameter \( \sigma = 4 \) it is obtained \([7]\) certain values of the parameters for which systems (1) and (3) possess self-excited attractors (Fig. 1a). An attractor is called a self-excited attractor if its basin of attraction intersects an arbitrarily small open neighborhood of an equilibrium, otherwise it is called a hidden attractor \([18–21]\). Self-excited attractors are relatively simple for localization and can be obtained using trajectories from an arbitrary small neighborhood of unstable equilibrium. The use of the term self-excited oscillation or self-oscillations can be traced back to the works of H.G. Barkhausen and A.A. Andronov, where it describes the generation and maintenance of a periodic motion in mechanical and electrical models by a source of power that lacks any corresponding periodicity (e.g., stable limit cycle in the van der Pol oscillator) \([22, 23]\). We use this notion for attractors of dynamical systems to describe the existence of transient process from a small vicinity of an unstable equilibrium to an attractor. If there is no such a transient process for an attractor, it is called a hidden attractor. The hidden and self-excited classification of attractors was introduced by Leonov and Kuznetsov in connection with the discovery of hidden Chua attractor \([18, 24, 25]\) and its rigorous consideration for autonomous and nonautonomous systems can be found in \([12, 20, 21, 26]\). For example, hidden attractors are attractors in systems without equilibria or with only one stable equilibrium (a special case of multistability and coexistence of...
attractors). Some examples of hidden attractors can be found in [12, 27–40]. Recently hidden attractors were localized [21, 41] in systems (1) and (3) (Fig. 1b).

By the Lyapunov function

\[ V(x, y, z) = \frac{1}{2} \left( x^2 + y^2 + (A + 1) \left( z - \frac{\sigma + r(A + 1)}{A + 1} \right)^2 \right) \]

it is proved [15] that system (3) possesses a bounded absorbing ellipsoid (thus it is dissipative in the sense of Levinson [21])

\[ B(r, \sigma, A) = \left\{ (x, y, z) \in \mathbb{R}^3 \mid V(x, y, z) \leq \frac{(\sigma + r)^2}{2(A + 1)} \right\} \]

and, thus, has a global attractor and generates a dynamical system. Also it is known [15] that for \( b = 1 \) the global attractor is located in the positive invariant set

\[ \Omega = \{ y^2 + z^2 \leq 2rz \}. \]

To obtain necessary conditions of the existence of self-excited attractor, we consider the stability of equilibria in system (3). According to [15], we have the following: if \( r < 1 \), then there is a unique equilibrium \( S_0 = (0, 0, 0) \) (the trivial case). If \( r > 1 \), then (3) has three equilibria: \( S_0 = (0, 0, 0) \) – saddle, and \( S_{1,2} = (\pm x_1, \pm y_1, z_1) \), where

\[ x_1 = \frac{\sigma b \sqrt{\xi}}{\sigma b + A \xi}, \quad y_1 = \sqrt{\xi}, \quad z_1 = \frac{\sigma \xi}{\sigma b + A \xi}, \quad \xi = \frac{\sigma b}{2A^2} \left[ A(r - 2) - \sigma + \sqrt{(Ar - \sigma)^2 + 4A\sigma} \right]. \]

The stability of \( S_{1,2} \) depends on the parameters, e.g. for \( b = 1, \sigma = 4 \) the stability domain [21] is shown in Fig. 2. Here for parameters from the non-shaded region, a self-excited attractor can be localized by a trajectory from a small neighborhood of \( S_0, S_1 \) or \( S_2 \). To get a numerical characteristic of chaos in a system using numerical methods, it is possible to compute a local Lyapunov dimension for this trajectory, what gives an estimation of Lyapunov dimension of the corresponding self-excited attractor. For the hidden attractor visualization in the considered systems we need to use special analytical-numerical procedures of searching for a point in its domain of attraction [21, 41]. Thus, the estimation of Lyapunov dimension of hidden attractors in the considered systems is a challenging task.

2. Preliminaries. Analytical estimates of the Lyapunov dimension

2.1. The Lyapunov dimension and Kaplan-Yorke formula

The concept of the Lyapunov dimension was suggested in the seminal paper by Kaplan and Yorke [42] for estimating the Hausdorff dimension of attractors. Later it has been developed and rigorously justified in a number of papers (see, e.g. [43–45] and others). The direct numerical computation of the Hausdorff dimension of chaotic attractors is often a problem of high numerical complexity (see, e.g. the discussion in [46]), thus, the estimates by the Lyapunov dimension are of interest (see, e.g. [13]). Along with numerical methods for computing the Lyapunov dimension there is an effective analytical approach, proposed by Leonov in 1991 [47] (see also [15, 48, 49]). The
Leonov method is based on a combination of the Douady-Oesterlé approach with the direct Lyapunov method. The advantage of the method is that it often allows one to estimate the Lyapunov dimension of attractor without localization of attractor in the phase space and, in many cases, to get an exact Lyapunov dimension formula [50–56]. Nowadays it is known various approaches to the definition of the Lyapunov dimension. Below we use a rigorous definition [49] of the Lyapunov dimension inspired by the Douady-Oesterlé theorem on the Hausdorff dimension of maps. Consider an autonomous differential equation
\[
\dot{u} = f(u),
\]
where \( f : U \subseteq \mathbb{R}^n \rightarrow \mathbb{R}^n \) is a continuously differentiable vector-function, \( U \) is an open set. Define by \( u(t, u_0) = u_0 \), and consider the evolutionary operator \( \varphi^t(u_0) = u(t, u_0) \). We assume the uniqueness and existence of solutions of (8) for \( t \in [0, +\infty) \). Then system (8) generates a dynamical system \( \{\varphi^t\}_{t \geq 0} \). Let a nonempty set \( K \subset U \) be invariant with respect to \( \{\varphi^t\}_{t \geq 0} \), i.e. \( \varphi^t(K) = K \) for all \( t \geq 0 \). Consider the linearization of system (8) along the solution \( \varphi^t(u) \):
\[
\dot{v} = J(\varphi^t(u))v, \quad J(u) = Df(u),
\]
where \( J(u) \) is the \( n \times n \) Jacobian matrix, the elements of which are continuous functions of \( u \). Suppose that \( \det J(u) \neq 0 \) \( \forall u \in U \). Consider a fundamental matrix of linearized system (9) \( D\varphi^t(u) \) such that \( D\varphi^0(u) = I \), where \( I \) is a unit \( n \times n \) matrix. Let \( \sigma_i(t, u) = \sigma_i(D\varphi^t(u)), \ i = 1, 2, \ldots, n, \) be the singular values of \( D\varphi^t(u) \) with respect to their algebraic multiplicity ordered so that \( \sigma_1(t, u) \geq \ldots \geq \sigma_n(t, u) > 0 \) for any \( u \in U \) and \( t \geq 0 \). The singular value function of order \( d \in [0, n] \) at \( u \in U \) is defined as
\[
\begin{align*}
\omega_0(D\varphi^t(u)) &= 1, \\
\omega_d(D\varphi^t(u)) &= \sigma_1(t, u) \cdots \sigma_{|d|}(t, u)\sigma_{|d|+1}(t, u)d^{-|d|}, \quad d \in (0, n), \\
\omega_n(D\varphi^t(u)) &= \sigma_1(t, u) \cdots \sigma_n(t, u),
\end{align*}
\]
where \( |d| \) is the largest integer less or equal to \( d \). For a certain moment of time \( t \) the local Lyapunov dimension of the map \( \varphi^t \) at the point \( u \in \mathbb{R}^n \) (or the finite-time local Lyapunov dimension of dynamical system \( \{\varphi^t\}_{t \geq 0} \)) is defined as [49]
\[
\dim_L(\varphi^t, u) = \max\{d \in [0, n] : \omega_d(D\varphi^t(u)) \geq 1\}
\]
and the Lyapunov dimension of the map \( \varphi^t \) (or the finite-time Lyapunov dimension of dynamical system \( \{\varphi^t\}_{t \geq 0} \)) with respect to invariant set \( K \) is defined as
\[
\dim_L(\varphi^t, K) = \sup_{u \in K} \dim_L(\varphi^t, u) = \sup_{u \in K} \max\{d \in [0, n] : \omega_d(D\varphi^t(u)) \geq 1\}.
\]

The following is a corollary of the fundamental Douady–Oesterlé theorem [43]

**Theorem 1.** For any fixed \( t > 0 \) the Lyapunov dimension of the map \( \varphi^t \) with respect to a compact invariant set \( K \), defined by (12), is an upper estimate of the Hausdorff dimension of the set \( K \): \( \dim_H K \leq \dim_L(\varphi^t, K) \).

For the estimation of the Hausdorff dimension of invariant compact set \( K \) one can use the map \( \varphi^t \) with any time \( t \) (e.g. \( t = 0 \) leads to the trivial estimate \( \dim_H K \leq n \)), therefore the best estimation is \( \dim_H K \leq \inf_{t \geq 0} \dim_L(\varphi^t, K) \). By the properties of the singular value function and the cocycle property of fundamental matrix we can prove [49] that
\[
\inf_{t \geq 0} \sup_{u \in K} \dim_L(\varphi^t, u) = \lim_{t \to +\infty} \sup_{u \in K} \dim_L(\varphi^t, u).
\]
This property allows one to introduce the Lyapunov dimension of dynamical system \( \{\varphi^t\}_{t \geq 0} \) with respect to compact invariant set \( K \) (often called the Lyapunov dimension of \( K \)) as [49]
\[
\dim_L(\{\varphi^t\}_{t \geq 0}, K) = \lim_{t \to +\infty} \dim_L(\varphi^t, K) = \lim_{t \to +\infty} \sup_{u \in K} \dim_L(\varphi^t, u)
\]
which is an upper estimation of the Hausdorff dimension
\[
\dim_H K \leq \dim_L(\{\varphi^t\}_{t \geq 0}, K).
\]

Consider a set of finite-time Lyapunov exponents (of singular values) at the point \( u \):
\[
\text{LE}_i(t, u) = \frac{1}{t} \ln \sigma_i(t, u), \quad i = 1, 2, \ldots, n \quad t > 0.
\]
Here the set \( \{ \text{LE}_i(t,u) \}_{i=1}^n \) is ordered by decreasing (i.e. \( \text{LE}_1(t,u) \geq \cdots \geq \text{LE}_n(t,u) \) for all \( t > 0 \)) since the singular values are ordered by decreasing. Define \( j(t,u) = \max \{ m : \sum_{i=1}^m \text{LE}_i(t,u) \geq 0 \} \), and let \( n > j(t,u) \geq 1 \). Then the Kaplan-Yorke formula [42] with respect to the finite-time Lyapunov exponents \( \{ \text{LE}_i(t,u) \}_{i=1}^n \) is as follows [49]
\[
d_{L}^{KY}(\{ \text{LE}_i(t,u) \}_{i=1}^n) = j(t,u) + \frac{\text{LE}_1(t,u) + \cdots + \text{LE}_{j(t,u)}(t,u)}{|\text{LE}_{j(t,u)+1}(t,u)|},
\]
and it coincides with the local Lyapunov dimension of the map \( \varphi^t \) at the point \( u \):
\[
\dim_{L}(\varphi^t, u) = d_{L}^{KY}(\{ \text{LE}_i(t,u) \}_{i=1}^n).
\]
Thus, the use of Kaplan-Yorke formula (17) with \( \{ \text{LE}_i(t,u) \}_{i=1}^n \) is rigorously justified by the Douady-Oesterle theorem. In the above formula if \( n > \dim_{L}(\varphi^t, u) \), then for \( j(t,u) = \lfloor \dim_{L}(\varphi^t, u) \rfloor \) and \( s(t,u) = \dim_{L}(\varphi^t, u) - \lfloor \dim_{L}(\varphi^t, u) \rfloor \) from (11) we have \( 0 = \frac{1}{t} \ln \omega_{j(t,u)+s(t,u)}(D\varphi^t(u)) = \sum_{i=1}^{s(t,u)} \text{LE}_i(t,u) + s(t,u) \text{LE}_{j(t,u)+1}(t,u) \).

It is known that while the topological dimensions are invariant with respect to Lipschitz homeomorphisms, the Hausdorff dimension is invariant with respect to Lipschitz diffeomorphisms and the noninteger Hausdorff dimension is not invariant with respect to homeomorphisms [57]. Since the Lyapunov dimension is used as an upper estimate of the Hausdorff dimension, its corresponding properties are important (see, e.g. [58]). Consider the dynamical system \( \{ \varphi^t \}_{t \geq 0}, (U \subseteq \mathbb{R}^n, \| \cdot \|) \) under the smooth change of coordinates \( w = h(u), \) where \( h : U \subseteq \mathbb{R}^n \rightarrow \mathbb{R}^n \) is a diffeomorphism. In this case the dynamical system \( \{ \varphi^t \}_{t \geq 0}, (U \subseteq \mathbb{R}^n, \| \cdot \|) \) is transformed to the dynamical system \( \{ \varphi^h_t \}_{t \geq 0}, (h(U) \subseteq \mathbb{R}^n, \| \cdot \|) \), and the compact set \( K \subseteq U \) invariant with respect to \( \{ \varphi^t \}_{t \geq 0} \) is mapped to the compact set \( h(K) \subseteq h(U) \) invariant with respect to \( \{ \varphi^h_t \}_{t \geq 0} \).

**Proposition 1.** (see, e.g. [49, 59]) The Lyapunov dimension of the dynamical system \( \{ \varphi^t \}_{t \geq 0} \) with respect to the compact invariant set \( K \) is invariant with respect to any diffeomorphism \( h : U \subseteq \mathbb{R}^n \rightarrow \mathbb{R}^n \), i.e.
\[
\dim_{L}(\{ \varphi^t \}_{t \geq 0}, K) = \dim_{L}(\{ \varphi^h_t \}_{t \geq 0}, h(K)).
\]

This property and a proper choice of smooth change of coordinates may significantly simplify the computation of the Lyapunov dimension of dynamical system (see also a discussion in [60]).

### 2.2. Computation of the Lyapunov dimension

For numerical computation of the finite-time Lyapunov exponents there are developed various continuous and discrete algorithms based on the singular value decomposition (SVD) of fundamental matrix \( D\varphi^t(u) \), which has the form \( D\varphi^t(u) = U(t,u)\Sigma(t,u)V^*(t,u) \). Here \( U(t,u)^*U(t,u) = I \equiv V(t,u)^*V(t,u) \) and \( \Sigma(t) = \text{diag}\{ \sigma_1(t,u), \ldots, \sigma_n(t,u) \} \) is a diagonal matrix with positive real diagonal entries, which are singular values of \( D\varphi^t(u) \) (thus the finite-time Lyapunov exponents can be computed from \( \Sigma(t) \) according to (16)). An implementation of the discrete SVD method for computing finite-time Lyapunov exponents \( \{ \text{LE}_i(t,u) \}_{i=1}^n \) in MATLAB can be found, e.g. in [21]. It should be noted that some other algorithms (e.g. Benettin’s [61] and Wolf’s [62] algorithms), widely used for the Lyapunov exponents computation, are based on the so-called QR decomposition and, in general, lead to the computation of the values called *finite-time Lyapunov exponents* of the fundamental matrix columns \( (y^1(t,u), \ldots, y^n(t,u)) = D\varphi^t(u) \) (or finite-time Lyapunov characteristic exponents, LCEs) at the point \( u \) in which case the set \( \{ \text{LE}_i(t,u) \}_{i=1}^n \) ordered by decreasing for \( t > 0 \) is defined as the set \( \{ \frac{1}{t} \ln \| y^i(t,u) \| \}_{i=1}^n \). The set \( \{ \text{LCE}_i(t,u) \}_{i=1}^n \) may significantly differ from the \( \{ \text{LE}_i(t,u) \}_{i=1}^n \) and, in the general, \( \dim_{L}(\varphi^t, u) = d_{L}^{KY}(\{ \text{LE}_i(t,u) \}_{i=1}^n) \neq d_{L}^{KY}(\{ \text{LCE}_i(t,u) \}_{i=1}^n) \). Also there are known various examples in which the results of Lyapunov exponents numerical computations substantially differ from analytical results [64, 65].

Applying the statistical physics approach and assuming the ergodicity (see, e.g. [42, 44, 66, 67]), the Lyapunov dimension \( \dim_{L}(\{ \varphi^t \}_{t \geq 0}, K) \) of attractor \( K \) are often approximated by the local Lyapunov dimension \( \dim_{L}(\varphi^t, u_0) \) and its limit value \( \lim_{t \rightarrow +\infty} \dim_{L}(\varphi^t, u_0) \) corresponding to a trajectory \( \{ \varphi^t(u_0) \}_{t \geq 0} \) that belongs to the attractor \( (u_0 \in K) \). However, from a practical point of view, the rigorous proof of ergodicity is a challenging task [44, 68-70] (e.g. even for the well-studied Lorenz system), which hardly can be done effectively in the general case.

\[\text{In contrast to the definition of the Lyapunov exponents of singular values, finite-time Lyapunov exponents of fundamental matrix columns may be different for different fundamental matrices (see, e.g. [59]). To get the set of all possible values of the Lyapunov exponents of fundamental matrix columns (the set with the minimal sum of values), one has to consider the so-called normal fundamental matrices [63]. Using, e.g. Courant-Fischer theorem, it is possible to show that LCE_1(t,u) = LE_1(t,u) and LE_i(t,u) ≤ LCE_i(t,u) for 1 < i ≤ n. For example, for the matrix [59] X(t) = \begin{pmatrix} 1 & g(t) & -1(t) \\ 0 & 1 & 1 \\ \end{pmatrix} we have the following ordered values: LCE_1(X(t)) = \max \{ \limsup_{t \rightarrow +\infty} \frac{1}{t} \ln |g(t)|, \limsup_{t \rightarrow +\infty} \frac{1}{t} \ln |g^{-1}(t)| \}, LCE_2(X(t)) = 0; LE_1(X(t)) = \min \{ \liminf_{t \rightarrow +\infty} \frac{1}{t} \ln |g(t)|, \liminf_{t \rightarrow +\infty} \frac{1}{t} \ln |g^{-1}(t)| \}. Thus, in general we have (see, e.g. discussion in [49]): \dim_{L}(\varphi^t, u) = d_{L}^{KY}(\{ \text{LE}_i(t,u) \}_{i=1}^n) \leq d_{L}^{KY}(\{ \text{LCE}_i(t,u) \}_{i=1}^n). \]
question (see discussion in [49, p.2146]) is whether there exists a critical path for each systems the Lyapunov dimension of self-excited attractor is less than the Lyapunov dimension of one of the unstable [[80, p.98, Question 1]]. The last part of the question was formulated in critical point of symmetrized Jacobian matrix. This is a generalization of ideas, discussed e.g. in [43, 78], on the Hausdorff dimension estimation by the eigenvalues of symmetrized Jacobian matrix. Consider the Kaplan-Yorke formula with respect to the ordered set of eigenvalues of the symmetrized Jacobian matrix. The proper choice of function ˙{\(\varphi\)} with respect to the ordered set of eigenvalues of the symmetrized Jacobian matrix. The proper choice of function ˙{\(\varphi\)} allows one to simplify the estimation of the partial sum of eigenvalues in the Lyapunov dimension by the eigenvalues of symmetrized Jacobian matrix. The proper choice of function ˙{\(\varphi\)} allows one to simplify the estimation of the partial sum of eigenvalues in the Lyapunov dimension by the eigenvalues of symmetrized Jacobian matrix. The proper choice of function ˙{\(\varphi\)} allows one to simplify the estimation of the partial sum of eigenvalues in the Lyapunov dimension by the eigenvalues of symmetrized Jacobian matrix.

\[
\frac{1}{2} \left( SJ(u(t,u_0)) S^{-1} + (SJ(u(t,u_0)) S^{-1})^* \right),
\]

ordered so that \(\lambda_1(u_0, S) \geq \cdots \geq \lambda_n(u_0, S)\) for any \(u_0 \in U\).

**Theorem 2.** Let \(d = (j + s) \in [1, n]\), where integer \(j = |d| \in \{1, \ldots, n\}\) and real \(s = (d - |d|) \in [0, 1]\). If there exist a differentiable scalar function \(V : U \subseteq \mathbb{R}^n \to \mathbb{R}^1\) and a nonsingular \(n \times n\) matrix \(S\) such that

\[
\sup_{u \in U} (\lambda_1(u, S) + \cdots + \lambda_j(u, S) + s\lambda_{j+1}(u, S) + \hat{V}(u)) < 0,
\]

where \(\hat{V}(u) = (\nabla(V))^* f(u)\), then for a compact invariant set \(K \subseteq U\) we have

\[
\dim_{\text{H}} K \leq \dim_{\text{L}}(\{\{\varphi^t\}_{t \geq 0}\}) \leq j + s.
\]

This theorem allows one to estimate the singular values in the Lyapunov dimension by the eigenvalues of symmetrized Jacobian matrix. The proper choice of function \(V(u)\) allows one to simplify the estimation of the partial sum of eigenvalues and the nonunitary nonsingular matrix \(S\) (i.e. \(S^{-1} \neq S^*\)) is used to make it possible the analytical computation of the eigenvalues. In Theorem 2 the constancy of the signs of \(V(u)\) or \(V(u)\) is not required. A generalization of the above result for the discrete-time dynamical systems can be found in [49]. Additionally, if a localization of invariant set \(K\) is known: \(K \subset K^c \subseteq U\), then one can check (20) on \(K^c\) only. Also we can consider the Kaplan-Yorke formula with respect to the ordered set of eigenvalues of the symmetrized Jacobian matrix: \(d_{\text{LY}}^K(\{\lambda_i(u, S)\}_{i=1}^n)\), and its supremum on the set \(K\) gives an upper estimation of the finite-time Lyapunov dimension.

**Proposition 2.** For a compact invariant set \(K\) and any nonsingular \(n \times n\) matrix \(S\) we have

\[
\dim_{\text{H}} K \leq \dim_{\text{L}}(\{\{\varphi^t\}_{t \geq 0}\}) \leq \sup_{u \in K} d_{\text{LY}}^K(\{\lambda_i(u, S)\}_{i=1}^n).
\]

This is a generalization of ideas, discussed e.g. in [43, 78], on the Hausdorff dimension estimation by the eigenvalues of symmetrized Jacobian matrix. Since the function \(u \mapsto \dim_{\text{H}}(\{\varphi^t\})\) is upper semi-continuous (see, e.g. [79, p.554]), for each \(t \geq 0\) there exists a critical point \(u(t) \in K\), which may be not unique, such that \(\sup_{u \in K} \dim_{\text{H}}(\{\varphi^t\}, u) = \dim_{\text{H}}(\{\varphi^t\}, u(t))\). An essential question (see discussion in [49, p.2146]) is whether there exists a critical path \(\gamma_{cr} = \{\varphi_{\text{GD}}(u_{cr})\}, t \geq 0\) such that for each \(t \geq 0\) one of the corresponding critical points belongs to the critical path: \(\varphi_{\text{GD}}(u_{cr}) = u(t)\), and, if so, whether the critical path is an equilibrium or a periodic solution. The last part of the question was formulated in [80, p.98, Question 1]. A conjecture on the Lyapunov dimension of self-excited attractors [82] is that for "typical" systems the Lyapunov dimension of self-excited attractor is less than the Lyapunov dimension of one of the unstable systems.
If for \(d = j + s\), defined by Theorem 2 (i.e. for \(d : \dim_{\mathcal{H}} K \leq d\)), at an equilibrium point \(u_{eq}^{cr} = \varphi^i(u_{eq}^{cr})\) for any \(t \geq 0\) the relation

\[
\dim_{\mathcal{L}}(\{\varphi^i\}_{t \geq 0}, u_{eq}^{cr}) = j + s
\]

holds, then for any compact invariant set \(K \supset u_{eq}^{cr}\) we get the exact Lyapunov dimension formula

\[
\dim_{\mathcal{L}}(\{\varphi^i\}_{t \geq 0}, K) = \dim_{\mathcal{L}}(\{\varphi^i\}_{t \geq 0}, u_{eq}^{cr}) = j + s.
\]

Next statement is used to compute the Lyapunov dimension at an equilibrium with the help of the corresponding eigenvalues.

**Proposition 3.** Suppose that at one of the equilibrium points of the dynamical system \(\{\varphi^i\}_{t \geq 0}: u_{eq} \equiv \varphi^i(u_{eq})\), \(u_{eq} \in U\), the matrix \(J(u_{eq})\) has simple real eigenvalues: \(\{\lambda_i(u_{eq})\}_{i=1}^n\), \(\lambda_i(u_{eq}) \geq \lambda_{i+1}(u_{eq})\). Then

\[
\dim_{\mathcal{L}}(\{\varphi^i\}_{t \geq 0}, u_{eq}) = d_{\mathcal{L}}^{\mathcal{LH}}(\{\lambda_i(u_{eq})\}_{i=1}^n).
\]

The proof follows from the invariance of the Lyapunov dimension and the fact that in this case there exists a nonsingular matrix \(S\) such that \(S J(u_{eq}) S^{-1} = \text{diag}(\lambda_1(u_{eq}), \ldots, \lambda_n(u_{eq}))\) and \(\dim_{\mathcal{L}}(S \varphi^i, Su_{eq}) \equiv d_{\mathcal{L}}^{\mathcal{LH}}(\{\lambda_i(u_{eq})\}_{i=1}^n)\) for any \(t > 0\).

For the study of continuous-time dynamical system in \(\mathbb{R}^3\), which possesses an absorbing ball (i.e. dissipative in the sense of Levinson), the following result [47] is useful. Consider a certain open set \(\mathcal{K} \subset U\), which is diffeomorphic to a ball, whose boundary \(\partial \mathcal{K}\) is transversal to the vectors \(f(u), u \in \partial \mathcal{K}\). Let the set \(\mathcal{K}\) be a positively invariant for the solutions of system (8), i.e. \(\varphi^i(\mathcal{K}) \subset \mathcal{K}, t \geq 0\).

**Theorem 3.** Suppose, a continuously differentiable function \(V : U \subseteq \mathbb{R}^3 \to \mathbb{R}\) and a non-degenerate matrix \(S\) exist such that

\[
\sup_{u \in \mathcal{K}} (\lambda_1(u, S) + \lambda_2(u, S) + \dot{V}(u)) < 0.
\]

Then \(\varphi^i(u_0)\) with any initial data \(u_0 \in \mathcal{K}\) tends to the stationary set of dynamical system \(\{\varphi^i\}_{t \geq 0}\) as \(t \to +\infty\).

In this case the minimal attracting invariant set \(K \subset \mathcal{K}\) consists of equilibria and in the case of a finite set of equilibrium points in the system we have \(\dim_{\mathcal{H}} K = 0\).

3. Main results. Analytical estimations of the Lyapunov dimension of G-D system

Let \(u = (x, y, z) \in U = \mathbb{R}^3\), \(\{\varphi_{\text{GD}}^i\}_{t \geq 0}\) is the dynamical system generated by (3) with positive parameters \(\sigma, r, A, b\), and \(K \subset \mathbb{R}^3\) is a compact invariant set of \(\{\varphi_{\text{GD}}^i\}_{t \geq 0}\).

By Theorems 2 and 3 it can be formulated the assertion on the Lyapunov dimension of \(\{\varphi_{\text{GD}}^i\}_{t \geq 0}\).

**Theorem 4.** Suppose that either the inequality \(b < 1\) or the inequalities \(b \geq 1, \sigma > b\) are valid.

If

\[
(r + \frac{\sigma}{A})^2 < \frac{(b + 1)(b + \sigma)}{A},
\]

then \(\varphi_{\text{GD}}^i(u)\) with any \(u \in U\) tends to an equilibrium as \(t \to +\infty\) (i.e. the minimal attractive set of \(\{\varphi_{\text{GD}}^i\}_{t \geq 0}\) is a set of equilibria and its Hausdorff dimension is zero).

If

\[
(r + \frac{\sigma}{A})^2 \geq \frac{(b + 1)(b + \sigma)}{A},
\]

then for any compact invariant set \(K\) of \(\{\varphi_{\text{GD}}^i\}_{t \geq 0}\) we have

\[
\dim_{\mathcal{L}}(\{\varphi_{\text{GD}}^i\}_{t \geq 0}, K) \leq 3 - \frac{2(b + 1)}{\sigma + 1 + \sqrt{(\sigma - 1)^2 + A(b + r)^2}},
\]

rigorously justify the usage of the local Lyapunov dimension \(\dim_{\mathcal{L}}((\varphi^i)_{t \geq 0}, u)\). Although it may seem that this definition allows to reduce computational complexity (since the supremum over the set \(K\) has to be computed only once for \(t = +\infty\)) as compared with the definition of (14) (where the supremum has to be computed for each \(t \in (0, +\infty)\)), it does not have a clear sense for a finite-time interval \((0, T)\), which can only be considered in numerical experiments. Remark also that \(\dim_{\mathcal{L}}(\varphi^i, K)\), according to the Douady–Oesterlé theorem, has clear sense for any fixed \(t\) and, thus, in numerical experiments it can be computed, according to (13), only for sufficiently large time \(t = T\) (i.e the supremum over the set \(K\) is computed only once for \(t = T\)).
Proof. The Jacobian matrix for system (3) is as follows

\[
J(u) = \begin{pmatrix}
-\sigma & \sigma - Az & -Ay \\
-1 & -x & 0 \\
y & x & -b
\end{pmatrix}.
\] (26)

Consider a matrix

\[
S = \begin{pmatrix}
-\frac{1}{\sqrt{A}} & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{pmatrix}.
\]

Then

\[
\frac{1}{2} (SJ(u)S^{-1} + (SJ(u)S^{-1})^*) = \begin{pmatrix}
-\sigma & -\sqrt{A}z - \frac{\sigma + Ar}{2\sqrt{A}} & 0 \\
-\sqrt{A}z - \frac{\sigma + Ar}{2\sqrt{A}} & -1 & 0 \\
0 & 0 & -b
\end{pmatrix},
\] (27)

and its characteristic polynomial has the form

\[
(\lambda + b) \left[ \lambda^2 + (\sigma + 1)\lambda + \sigma - \left( \sqrt{A}z + \frac{\sigma + Ar}{2\sqrt{A}} \right)^2 \right].
\]

Denote by \(\lambda_i = \lambda_i(u, S), i = 1, 2, 3\), the eigenvalues of matrix (27). Then

\[
\lambda_2 = -b,
\]

\[
\lambda_{1,3} = -\frac{(\sigma + 1)}{2} \pm \frac{1}{2} \sqrt{(\sigma - 1)^2 + 4 \left( \sqrt{A}z + \frac{\sigma + Ar}{2\sqrt{A}} \right)^2}.
\]

Thus, \(\lambda_1 > \lambda_3\) and \(\lambda_3 < 0\). Let us find the conditions under which the inequality \(\lambda_2 > \lambda_3\) holds, i.e.

\[
\lambda_2 - \lambda_3 = -b + \frac{1}{2}(\sigma + 1) + \frac{1}{2} \sqrt{(\sigma - 1)^2 + 4 \left( \sqrt{A}z + \frac{\sigma + Ar}{2\sqrt{A}} \right)^2} > 0.
\] (28)

If \((\sigma + 1) > 2b\), then inequality (28) is valid. If \((\sigma + 1) \leq 2b\), then inequality (28) is equivalent to the following relation

\[
(\sigma + 1)^2 + 4b^2 - 4b(\sigma + 1) < (\sigma - 1)^2 + 4 \left( \sqrt{A}z + \frac{\sigma + Ar}{2\sqrt{A}} \right)^2
\]

\[
\Leftrightarrow \sigma - b\sigma - b + b^2 < \left( \sqrt{A}z + \frac{\sigma + Ar}{2\sqrt{A}} \right)^2 \Leftrightarrow (\sigma - b)(1 - b) < \left( \sqrt{A}z + \frac{\sigma + Ar}{2\sqrt{A}} \right)^2.
\]

The latter is true in the case when \((\sigma - b)(1 - b) < 0\). Hence, if the inequalities

\[
(\sigma + 1) > 2b \quad \text{or} \quad \begin{cases} (\sigma + 1) \leq 2b, \\ (\sigma - b)(1 - b) < 0 \end{cases}
\] (29)

hold, then \(\lambda_2 > \lambda_3\). Inequalities (29) are equivalent to the following expressions

\[
b < 1 \quad \text{or} \quad \begin{cases} b \geq 1, \\ \sigma > b \end{cases}
\] (30)

and the conditions of Theorem 4 are fulfilled. This implies that under these conditions \(\lambda_3\) is the smallest eigenvalue.

Consider \(s \in [0, 1]\) and the following relations

\[
2(\lambda_1 + \lambda_2 + s\lambda_3) = -(\sigma + 1 + 2b) - s(\sigma + 1) + (1 - s) \sqrt{(\sigma - 1)^2 + 4 \left( \sqrt{A}z + \frac{\sigma + Ar}{2\sqrt{A}} \right)^2}
\]

\[
\leq -(\sigma + 1 + 2b) - s(\sigma + 1) + (1 - s) \left[ (\sigma - 1)^2 + A \left( \frac{\sigma}{A} + r \right)^2 \right] + 
\]

\[
+ \frac{2(1 - s)}{\left[ (\sigma - 1)^2 + A \left( \frac{\sigma}{A} + r \right)^2 \right]^2} \left[ -(\sigma + Ar)z + Az^2 \right].
\]
Denote
\[ w(x, y, z) = -(\sigma + Ar)z + Az^2. \] (31)

Choose the Lyapunov-like function \( V(x, y, z) \) as follows
\[ V(x, y, z) = \frac{2(1-s)}{[(\sigma - 1)^2 + A(\frac{r}{2} + r)^2]^2} \vartheta(x, y, z), \]
where \( \vartheta(x, y, z) = \gamma_1x^2 + \gamma_2y^2 + \gamma_3z^2 + \gamma_4z \) and \( \gamma_1, \gamma_2, \gamma_3, \gamma_4 \) are varying parameters.

Differentiation of \( \vartheta \) along solutions of system (3) yields
\[
\dot{\vartheta}(x, y, z) = 2(\gamma_3 - \gamma_2 - \gamma_1 A)xyz - 2\gamma_1\sigma x^2 + (2\gamma_1 \sigma + \gamma_4 + 2\gamma_2 r)xy - 2\gamma_2 y^2 - 2\gamma_3bz z - \gamma_4 b z. \] (32)

Thus
\[
\dot{\vartheta}(x, y, z) + w(x, y, z) = 2(\gamma_3 - \gamma_2 - \gamma_1 A)xyz + (2\gamma_1 \sigma + \gamma_4 + 2\gamma_2 r)xy - 2\gamma_2 y^2 - 2\gamma_1\sigma x^2 + (A - 2\gamma_3 b) z^2 - (\sigma + Ar + \gamma_4 b) z.
\]
Parameters \( \gamma_1, \gamma_2, \gamma_3, \gamma_4 \) are chosen such that \( \dot{\vartheta}(x, y, z) + w(x, y, z) \) takes the form of polynomial
\[ A_1 x^2 + A_2 xy + A_3 y^2 + B_1 z^2, \] (33)
i.e. the coefficients of monomials \( xyz \) and \( z \) in (32) are zero and
\[ \gamma_3 = A\gamma_1 + \gamma_2, \quad \gamma_4 = -\frac{\sigma + Ar}{b}. \] (34)

From (34) we have
\[
\dot{\vartheta}(x, y, z) + w(x, y, z) = -2\gamma_1\sigma x^2 + (2\gamma_1 \sigma - \frac{\sigma + Ar}{b} + 2\gamma_2 r)xy - 2\gamma_2 y^2 + (-2b(A\gamma_1 + \gamma_2) + A) z^2
\]
\[ = A_1 x^2 + A_2 xy + A_3 y^2 + B_1 z^2, \]
where
\[ A_1 = -2\gamma_1 \sigma, \quad A_2 = 2\gamma_1 \sigma - \frac{\sigma + Ar}{b} + 2\gamma_2 r, \quad A_3 = -2\gamma_2, \quad B_1 = -2b(A\gamma_1 + \gamma_2) + A. \] (35)

Polynomial (33) can be written as
\[ A_3 \left( y + \frac{A_2}{2A_3} x \right)^2 + \frac{4A_1 A_3 - A_3^2}{4A_3} x^2 + B_1 z^2. \]

Hence the inequality \( \dot{\vartheta}(x, y, z) + w(x, y, z) \leq 0 \) holds if and only if
\[ B_1 \leq 0, \quad A_3 < 0, \quad A_1 A_3 - \left( \frac{A_3^2}{2} \right) \geq 0. \] (36)

Combining (35) with (36), we obtain
\[ \gamma_2 > 0, \quad \gamma_1 \geq 1 - \frac{1}{A} \gamma_2, \] (37)
\[ 4\sigma \gamma_1 \gamma_2 - \left( \gamma_1 \sigma - \frac{\sigma + Ar}{2b} + \gamma_2 r \right)^2 \geq 0. \] (38)

Inequality (39) is solvable with respect to \( \gamma_1 \) if and only if its discriminant is nonnegative:
\[ D = 8\sigma^2 \gamma_2 \left( 2\gamma_2 (1 - r) + \frac{\sigma + Ar}{b} \right) \geq 0. \]

By (37) and since \( r > 1 \), the latter is equivalent to the following relation
\[ 2\gamma_2 (r - 1) \leq \frac{\sigma + Ar}{b} \quad \Leftrightarrow \quad \gamma_2 \leq \frac{\sigma + Ar}{2(r - 1)b}. \] (40)
Hence if condition (40) holds, then (39) is equivalent to the relation \( \Gamma_-(\gamma_2) \leq \gamma_1 \leq \Gamma_+ (\gamma_2) \), where

\[
\Gamma_{\pm}(\gamma_2) = \frac{1}{\sigma} \left[ \gamma_2(2 - r) + \frac{\sigma + Ar}{2b} \pm \sqrt{2\gamma_2 \left( 2(1-r)\gamma_2 + \frac{\sigma + Ar}{b} \right)} \right]
\]

(41)

are the roots of quadratic polynomial in the left-hand side of (39).

Consider now the location of the roots \( \Gamma_{\pm}(\gamma_2) \) on the real axis. If \( 1 < r \leq 2 \), then by (37) we have \( \gamma_2(2 - r) + \frac{\sigma + Ar}{2b} \geq 0 \). If \( r > 2 \), then by (40) the relation

\[
\gamma_2(2 - r) + \frac{\sigma + Ar}{2b} \geq 0 \quad \iff \quad \gamma_2 \leq \frac{\sigma + Ar}{2(r - 2)b}
\]

holds since

\[
\frac{\sigma + Ar}{2(r - 1)b} \leq \frac{\sigma + Ar}{2(r - 2)b}.
\]

Thus, for \( \gamma_2 \), defined by (37) and (40), and \( r > 1 \) we have \( \gamma_2(2 - r) + \frac{\sigma + Ar}{2b} \geq 0 \) and \( \Gamma_+ (\gamma_2) \geq 0 \).

Let us prove that for \( \gamma_2 \), defined by (37) and (40), we have \( \Gamma_-(\gamma_2) \geq 0 \). It is true since

\[
\gamma_2(2 - r) + \frac{\sigma + Ar}{2b} \geq \sqrt{2\gamma_2 \left( 2(1-r)\gamma_2 + \frac{\sigma + Ar}{b} \right)} \iff \left( \gamma_2(2 - r) + \frac{\sigma + Ar}{2b} \right)^2 \geq 2\gamma_2 \left( 2(1-r)\gamma_2 + \frac{\sigma + Ar}{b} \right)
\]

\[
\iff r^2 \gamma_2^2 - \frac{\sigma + Ar}{b} r \gamma_2 + \left( \frac{\sigma + Ar}{2b} \right)^2 = \left( r \gamma_2 - \frac{\sigma + Ar}{2b} \right)^2 \geq 0.
\]

Hence if \( r > 1 \), then \( 0 \leq \Gamma_-(\gamma_2) \leq \gamma_1 \leq \Gamma_+(\gamma_2) \).

Let \( \Gamma(\gamma_2) = \frac{1}{2b} - \frac{A}{4} \gamma_2 \). Thus if \( r > 1 \), the conditions (30) holds, and there exist nonnegative \( \gamma_1, \gamma_2 \) such that a system of inequalities

\[
\begin{cases}
0 < \gamma_2 \leq \frac{\sigma + Ar}{2(r - 1)b}, \\
\max \{ \Gamma(\gamma_2), \Gamma_-(\gamma_2) \} \leq \gamma_1 \leq \Gamma_+(\gamma_2)
\end{cases}
\]

(42)

is solvable, then the inequality \( \dot{\gamma} + w \leq 0 \) is valid.

Let us show that system (42) is solvable. Note that

\[
\Gamma_+(0) = \Gamma_-(0) = \frac{\sigma + Ar}{2b} > 0,
\]

\[
\Gamma_+ \left( \frac{\sigma + Ar}{2b(r-1)} \right) = \Gamma_- \left( \frac{\sigma + Ar}{2b(r-1)} \right) = \frac{\sigma + Ar}{2b(r-1)} > 0,
\]

\[
\Gamma(0) = \frac{1}{2b} > 0, \quad \Gamma \left( \frac{\sigma + Ar}{2b(r-1)} \right) = -\frac{\sigma + A}{2b(r-1)}A < 0.
\]

This implies that the upper half plane, defined by the inequality \( \gamma_1 \geq \Gamma(\gamma_2) \), always intersects the domain bounded by the curves \( \Gamma_{\pm}(\gamma_2) \). This intersection corresponds to the existence domain of solutions of system (42).

Thus, for the chosen matrix \( S \) and Lyapunov-like function \( V(x, y, z) \) if (24) is valid and

\[
s > \frac{-(\sigma + 1 + 2b) + \sqrt{(\sigma - 1)^2 + A \left( \frac{\sigma}{4} + r \right)^2}}{\sigma + 1 + \sqrt{(\sigma - 1)^2 + A \left( \frac{\sigma}{4} + r \right)^2}},
\]

(43)

then for system (3) the conditions of Theorem 2 hold. If (23) is valid and \( s = 0 \), then for system (3) the conditions of Theorem 3 hold.

Hence if (24) holds, then \( \dim_L(\{ \varphi_{\text{GD}}^t \}_{t \geq 0}, K) \leq 2 + s \) for all \( s \), satisfying (43). This implies inequality (25) and completes the proof of the theorem.

For system (3) with physically sounded value of parameter \( b = 1 \), the upper estimate (25) can be improved [84].
Theorem 5. Let \( b = 1 \) and \( \sigma \geq Ar \). If

\[
\frac{2(\sigma + 2)}{\sigma + 1 + \sqrt{(\sigma - 1)^2 + 4\sigma r}} \leq 1, \tag{44}
\]

then

\[
\dim_L(\{\varphi^t_{GD}\}_{t \geq 0}, K) \leq 3 - \frac{2(\sigma + 2)}{\sigma + 1 + \sqrt{(\sigma - 1)^2 + 4\sigma r}}. \tag{45}
\]

Proof. Here we use the following idea suggested by Leonov \[?\]. The relation

\[
\frac{1}{2}(SJ(u)S^{-1} + (SJ(u)S^{-1})^*) + \mu I > 0, \tag{46}
\]

where \( \mu = -\text{Tr} J(u) = \sigma + b + 1 = \frac{\sigma + 2}{\sigma} \) and \( s \in [0, 1) \) is equivalent to condition (20) of Theorem 2 with \( V \equiv 0 \). Note that \( \text{Tr} J(u) = \lambda_1(u, S) + \lambda_2(u, S) + \lambda_3(u, S) \). The positive definiteness of matrix (46) means that \( \lambda_3(u, S) + \mu > 0 \iff \lambda_1(u, S) + \lambda_2(u, S) + s\lambda_3(u, S) < 0 \).

Consider a matrix

\[
S = \begin{pmatrix} \sqrt{\frac{\sigma}{2}} & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.
\]

Condition (46) means that all leading principal minors \( \Delta_{1,2,3} \) of the corresponding matrix are positive. For the chosen matrix \( S \) we have \( \Delta_1 = -\sigma + \mu > 0 \), \( \Delta_3 = (-1 + \mu) \Delta_2 \) and relation (46) can be expressed in the following way

\[
\Delta_3 = \begin{vmatrix} -\sigma + \mu & \sqrt{r\sigma} - \frac{s}{2} \sqrt{\frac{\sigma}{2}} (1 + \frac{Ar}{\sigma}) & \frac{s}{2} \sqrt{\frac{\sigma}{2}} (1 - \frac{Ar}{\sigma}) \\ \sqrt{r\sigma} - \frac{s}{2} \sqrt{\frac{\sigma}{2}} (1 + \frac{Ar}{\sigma}) & -1 + \mu & 0 \\ \frac{s}{2} \sqrt{\frac{\sigma}{2}} (1 - \frac{Ar}{\sigma}) & 0 & -1 + \mu \end{vmatrix} > 0. \tag{47}
\]

Condition (47) can be rewritten as

\[
\frac{r}{\sigma} ((\mu - \sigma)(\mu - d) - r\sigma) + \left(1 + \frac{Ar}{\sigma}\right) \left(-\frac{z^2}{4} (1 + \frac{Ar}{\sigma}) - \frac{y^2}{4} (1 + \frac{Ar}{\sigma})^2 + rz\right) > 0.
\]

One can see that for \( b = 1 \), \( \sigma \geq Ar \) and \( V \equiv 0 \) condition (20) holds for all \((x, y, z)\) from \( \Omega(x, y, z) \) (see (7)) if

\[
r \leq \frac{(\mu - \sigma)(\mu - 1)}{\sigma}. \tag{48}
\]

The expression \( r = \frac{(\mu - \sigma)(\mu - 1)}{\sigma} \) is equivalent to the relation

\[
\frac{2(\sigma + 2)}{\sigma + 1 + \sqrt{(\sigma - 1)^2 + 4\sigma r}} = 1 - s.
\]

Thus, if (44) is valid, then all the conditions of Theorem 2 for system (3) hold.

The obtained result is a development of results from \([21, 84]\) for all values of parameters for which the transformation of system (3) to (1) is valid (see conditions (5)).

Theorems 4 and 5 imply the following

Corollary 1. If

(i) \( \sigma = Ar, b < 1 \) or

(ii) \( \sigma = Ar, b \geq 1, \sigma > b \) or

(iii) \( \sigma \geq Ar, b = 1 \)

and

\[
\frac{2(\sigma + b + 1)}{\sigma + 1 + \sqrt{(\sigma - 1)^2 + 4\sigma r}} \leq 1,
\]

then the Lyapunov dimension of the zero equilibrium of \( \{\varphi^t_{GD}\}_{t \geq 0} \) coincides with (45) and for any compact invariant set \( K \supseteq S_0 = (0, 0, 0) \) we get the exact Lyapunov dimension formula

\[
\dim_L(\{\varphi^t_{GD}\}_{t \geq 0}, K) = \dim_L(\{\varphi^t_{GD}\}_{t \geq 0}, S_0) = 3 - \frac{2(\sigma + b + 1)}{\sigma + 1 + \sqrt{(\sigma - 1)^2 + 4\sigma r}}. \tag{49}
\]
Proof. The Jacobi matrix \( J(u) \) from equation (26) at equilibrium \( u = S_0 \) has the following simple real eigenvalues

\[
\lambda_{1,3}(S_0) = \frac{1}{2} \left( -(\sigma + 1) \pm \sqrt{(\sigma - 1)^2 + 4\sigma r} \right), \quad \lambda_2(S_0) = -b. \tag{50}
\]

For \( r > 1 \), we have \( \lambda_1(S_0) > 0, \lambda_{2,3}(S_0) < 0 \). If (i) or (iii), then it follows that \( \lambda_2(S_0) > \lambda_3(S_0), \lambda_1(S_0) + \lambda_2(S_0) + \lambda_3(S_0) = -\sigma - b - 1 < 0 \) and from (44) it follows that \( \lambda_1(S_0) + \lambda_2(S_0) \geq 0 \). Then according to (17) we have

\[
d_{L}^{KY} (\{\lambda_i(S_0)\}_{i=1}^{n}) = 2 + \frac{\lambda_1(S_0) + \lambda_2(S_0)}{|\lambda_3(S_0)|} = 2 + \frac{-(\sigma + 1 - 2b) + \sqrt{(\sigma - 1)^2 + 4\sigma r}}{\sigma + 1 + \sqrt{(\sigma - 1)^2 + 4\sigma r}} = 3 - \frac{2(\sigma + b + 1)}{\sigma + 1 + \sqrt{(\sigma - 1)^2 + 4\sigma r}}.
\]

By Proposition 3

\[
\dim_L (\varphi_{GD}^{t} \{S_0\}) = d_{L}^{KY} (\{\lambda_i(S_0)\}_{i=1}^{n}) = 3 - \frac{2(\sigma + b + 1)}{\sigma + 1 + \sqrt{(\sigma - 1)^2 + 4\sigma r}}
\]

and according to Corollary 1 for any compact invariant set \( K \supset S_0 \) we get (49). \( \square \)

Note that formula (49) coincides with the exact Lyapunov dimension formula for the classical Lorenz system [50, 56, 60]. In the Lorenz system the maximum of the local Lyapunov dimensions is also achieved at the zero equilibrium and this fact is known as the so-called Eden conjecture on the Lorenz system [80, 85–87]. The main direction of its further study is to extend the domain of parameters for which the exact Lyapunov dimension formula for the Lorenz system is valid.

4. Numerical experiments and discussion of the results

Below we consider the dynamical system \( \{\varphi_{GD}^{t} \} \), generated by the generalized Lorenz system (3), various types of its attractors \( K \), and their Lyapunov dimensions. Here \( \varphi_{GD}^{t}(x_0, y_0, z_0) \) is a solution of (3) with the initial condition \( (x_0, y_0, z_0) \), i.e.

\[
\varphi_{GD}^{t}(x_0, y_0, z_0) = (x(t, (x_0, y_0, z_0)), y(t, (x_0, y_0, z_0)), z(t, (x_0, y_0, z_0))).
\]

Let \( \rho(K, u) = \inf_{v \in K} \|v - u\| \) be the distance from the point \( u \in U \) to the set \( K \subset U \). For a dynamical system \( \{\varphi^{t}\} \), a bounded closed invariant set \( K \) is [21]:

(i) a (local) attractor if it is a minimal locally attractive set (i.e., \( \lim_{t \to +\infty} \rho(K, \varphi^{t}(u)) = 0 \) for all \( u \in K(\delta) \), where \( K(\varepsilon) \) is a certain \( \varepsilon \)-neighborhood of set \( K) \),

(ii) a global attractor if it is a minimal globally attractive set (i.e., \( \lim_{t \to +\infty} \rho(K, \varphi^{t}(u)) = 0 \) for all \( u \in \mathbb{R}^{n} \)),

(iii) a (local) \( B \)-attractor if it is a minimal uniformly locally attractive set (i.e., for a certain \( K(\varepsilon) \), any \( \delta > 0 \), and any bounded set \( B \) there exists \( t(\delta, B) > 0 \) such that \( \varphi^{t}(B \cap K(\varepsilon)) \subset K(\delta) \) for all \( t \geq t(\delta, B) \)),

(iv) a global \( B \)-attractor if it is a minimal uniformly globally attractive set (i.e., for any \( \delta > 0 \) and any bounded set \( B \subset \mathbb{R}^{n} \) there exists \( t(\delta, B) > 0 \) such that \( \varphi^{t}(B) \subset K(\delta) \) for all \( t \geq t(\delta, B) \)).

In the definition of attractor we assume closeness for the sake of uniqueness since the closure of a locally attractive invariant set is also a locally attractive invariant set (e.g., consider an attractor with excluded one of the embedded unstable periodic orbits). The above definition implies that a global attractor involves the set of all equilibria. The property of uniform attractivity implies that a global \( B \)-attractor involves the unstable manifolds of unstable equilibrium (the same is true for \( B \)-attractor if its neighborhood considered contains some unstable equilibria). If the dynamical system \( \{\varphi^{t}\} \) possesses an absorbing set \( B \), then the global attractor can be constructed as follows: \( \cap_{t > 0} \{\varphi^{t} \} \).

In the following, we consider system (3) with two sets of parameters: \( b = 1, \sigma = 4, A = 0.0052 \), and \( r = 687.5 \) or \( r = 700 \), and visualize possible types of attractors in Fig. 3 and Fig. 4, respectively. Visualizations of chaotic self-excited (\( r = 687.5 \)) and hidden (\( r = 700 \)) attractors in Fig. 3 and Fig. 4 are obtained by numerical integration of system (3) on the time-interval [0, 60] with initial condition \( P_{1} = (10, 60, 800) \) and visualizations of numerical solutions after a transient process (the separation of the trajectory into transition process and approximation of attractor is rough).
Global attractor (the union of equilibria $S_{0,1,2}$ and local self-excited attractor). Figure 3: Monostability. Numerical visualization of various types of attractors in system (3) with $b = 1$, $r = 687.5$.

Further we use the compact notations for the finite-time Lyapunov dimensions: $\dim_L(t,u) = \dim_L(\varphi_{GD}^t, u)$, $\dim_L(t,K) = \dim_L(\varphi_{GD}^t, K)$, and for the Lyapunov dimension: $\dim_L K = \dim_L(\varphi_{GD}^t; t \geq 0, K)$. For the chosen initial point $u_0 = (x_0,y_0,z_0)$ and time interval $[0,T]$, which are used to visualize the attractor $K$, there are the following substantial questions related to the computation of the finite-time Lyapunov dimension of $K$. The first question is whether there exists the limit $\lim_{t \to +\infty} \dim_L(\varphi^t, K) = \dim_L K$ and, if not, whether for a given time interval $[0,T]$ the relation $\dim_L(T,K) \leq \inf_{t \in [0,T]} \dim_L(t,K)$ is true. In general, there is no rigorous justification of the choice of $t$ and it is known that unexpected jumps of $\dim_L(t,K)$ can occur (see, e.g. Fig. 6). Thus it is reasonable to compute $\inf_{t \in [0,T]} \dim_L(\varphi^t, K)$ instead of $\dim_L(T,K)$, but at the same time for any $T$ the value $\dim_L(T,K)$ gives also a valid upper estimate for $\dim_L K$. The second question is whether a given initial point $u_0$ belongs to the attractor $K$ or only to its basin of attraction (and thus the whole semi-orbit $\varphi_{GD}^t(u_0), t \geq 0$ belongs only to the basin of attraction), and, if yes, whether $u_0$ is substantial for the Lyapunov dimension, i.e. whether the relation $\dim_L(K) = \dim_L(u_0)$ is true or $\dim_L(K) = \dim_L(K \setminus u_0)$. Since it is a challenging task to give justified answers to these questions, for numerical computation of the Lyapunov dimension we have to consider a dense grid of points $K_{\text{grid}}$ on a numerical approximation (visualization) of $K$ and approximate the Lyapunov dimension of attractor $K$ by $\max_{u \in K_{\text{grid}}} \dim_L(t,u)$. Finally, in numerical experiments we can expect

$$\dim_H K \leq \dim_L K \approx \inf_{t \in [0,T]} \max_{u \in K_{\text{grid}}} \dim_L(t,u) = \max_{u \in K_{\text{grid}}} \dim_L(t_{\inf}, u) \leq \max_{u \in K_{\text{grid}}} \dim_L(T,u) \approx \dim_L(T,K).$$

In Fig. 5 is shown the grid of points $C^h_{\text{grid}}$ covering the hidden attractor: the grid points fill cuboid $C^h = [-30, 25] \times [-330, 300] \times [395, 956]$ with the distance between points equals 5; the grid of points $C^{se}_{\text{grid}}$ covering self-excited attractor fill cuboid $C^{se} = [-25, 25] \times [-305, 290] \times [410, 930]$). The time interval is $[0, 60]$ and the integration method is MATLAB ode45. Remark that if for a certain time the computed trajectory is out of the cuboid, the corresponding value of finite-time local Lyapunov dimension does not taken into account in the computation of maximum of the finite-time local Lyapunov dimension (there are trajectories with initial data in cuboid, which are attracted to the zero equilibria, i.e. belong to its stable manifold, e.g. system (3) for $x = y = 0$ is $z = -bz$). The

Further we use the compact notations for the finite-time Lyapunov dimensions: $\dim_L(t,u) = \dim_L(\varphi_{GD}^t, u)$, $\dim_L(t,K) = \dim_L(\varphi_{GD}^t, K)$, and for the Lyapunov dimension: $\dim_L K = \dim_L(\varphi_{GD}^t; t \geq 0, K)$. For the chosen initial point $u_0 = (x_0,y_0,z_0)$ and time interval $[0,T]$, which are used to visualize the attractor $K$, there are the following substantial questions related to the computation of the finite-time Lyapunov dimension of $K$. $$\dim_H K \leq \dim_L K \approx \inf_{t \in [0,T]} \max_{u \in K_{\text{grid}}} \dim_L(t,u) = \max_{u \in K_{\text{grid}}} \dim_L(t_{\inf}, u) \leq \max_{u \in K_{\text{grid}}} \dim_L(T,u) \approx \dim_L(T,K).$$

In Fig. 5 is shown the grid of points $C^h_{\text{grid}}$ covering the hidden attractor: the grid points fill cuboid $C^h = [-30, 25] \times [-330, 300] \times [395, 956]$ with the distance between points equals 5; the grid of points $C^{se}_{\text{grid}}$ covering self-excited attractor fill cuboid $C^{se} = [-25, 25] \times [-305, 290] \times [410, 930]$). The time interval is $[0, 60]$ and the integration method is MATLAB ode45. Remark that if for a certain time the computed trajectory is out of the cuboid, the corresponding value of finite-time local Lyapunov dimension does not taken into account in the computation of maximum of the finite-time local Lyapunov dimension (there are trajectories with initial data in cuboid, which are attracted to the zero equilibria, i.e. belong to its stable manifold, e.g. system (3) for $x = y = 0$ is $z = -bz$). The
\[ \mathcal{B}^h = \left\{ (x, y, z) \in \mathbb{R}^3 \mid \left(x^2 + y^2 + (A + 1) \left(\frac{z - \sigma + r}{A + 1}\right)^2\right) \leq \left(\frac{(\sigma + r)}{(A + 1)}\right)^2 \right\} \]

\[ C^h_{\text{grid}} \subset C^h \]

Figure 5: Localization of the hidden attractor by the absorbing set \( \mathcal{B}^h \), cuboid \( C^h = [-30, 25] \times [-330, 300] \times [395, 956] \), and the corresponding grid of points \( C^h_{\text{grid}} \).

Ininfimum on the time interval is computed at the points \{\( t_k \}\}^N with time step \( t_\Delta = t_{i+1} - t_i = 0.1 \). Note that if for a certain time \( t = t_k \) the computed trajectory is out of the cuboid, the corresponding value of finite-time local Lyapunov dimension does not taken into account in the computation of maximum of the finite-time local Lyapunov dimension (there are trajectories with initial data in cuboid, which are attracted to the zero equilibria, i.e. belong to its stable manifold, e.g. system (3) for \( x = y = 0 \) is \( \dot{z} = -bz \)). For the finite-time Lyapunov exponents (FTLE) computation we use MATLAB realization \cite{21} of a method, based on SVD decompositions. For computation of the finite-time Lyapunov characteristic exponents (FTLCE) we use MATLAB realization \cite{77} of a method, based on QR decompositions.

For both sets of parameters (see Fig. 3 and Fig. 4) we compute: 1) finite-time local Lyapunov dimensions \( \dim_L(t, u) \) at the point \( P_1 = (10, 60, 800) \), which belong to both grids \( C^h_{\text{grid}} \), at the point \( P_2 = (-0.0074, -0.0997, 0) \) on the unstable manifold of zero equilibria \( S_0 \); 2) maximums of the finite-time local Lyapunov dimensions at the points of grid \( \max_{u \in C^h_{\text{grid}}} \dim_L(t, u) \) for the time points \( t = t_k = 0.1k \ (k = 1, ..., 600) \) and the infimum of the maximums; 3) the corresponding values, given by Kaplan-Yorke formula with respect to finite-time Lyapunov characteristic exponents. The results are given in Table 1 and 2.

**Table 1:** The set of parameters corresponding the self-excited attractor (see Fig. 3)

| \( \dim_L(t, u) \) (SVD) | \( t = 60 \) \( u = (10, 60, 800) \) | \( t = 60 \) \( u = (-0.0074, -0.0997, 0) \) | \( \dim_L(t, u) \) (QR) |
|------------------------|-----------------|-----------------|------------------------|
| \( \dim_L(t, u) \) (SVD) | 2.1345 | 2.1468 | 2.1721 |
| \( \dim_L(t, u) \) (QR) | 2.1414 | 2.1262 | 2.1876 |

**Table 2:** The set of parameters corresponding the hidden attractor (see Fig. 4)

| \( \dim_L(t, u) \) (SVD) | \( t = 60 \) \( u = (10, 60, 800) \) | \( t = 60 \) \( u = (-0.0074, -0.0997, 0) \) | \( \dim_L(t, u) \) (QR) |
|------------------------|-----------------|-----------------|------------------------|
| \( \dim_L(t, u) \) (SVD) | 2.1271 | 1.2335 | 2.1372 |
| \( \dim_L(t, u) \) (QR) | 2.1372 | 1.0139 | 2.1372 |

\[ d_{\text{KY}}^V \left\{ \{LCE_i(t, u)\}^3_{i=1} \right\} \]

For both sets of parameters (see Fig. 3 and Fig. 4) we compute: 1) finite-time local Lyapunov dimensions \( \dim_L(t, u) \) at the point \( P_1 = (10, 60, 800) \), which belong to both grids \( C^h_{\text{grid}} \), at the point \( P_2 = (-0.0074, -0.0997, 0) \) on the unstable manifold of zero equilibria \( S_0 \); 2) maximums of the finite-time local Lyapunov dimensions at the points of grid \( \max_{u \in C^h_{\text{grid}}} \dim_L(t, u) \) for the time points \( t = t_k = 0.1k \ (k = 1, ..., 600) \) and the infimum of the maximums; 3) the corresponding values, given by Kaplan-Yorke formula with respect to finite-time Lyapunov characteristic exponents. The results are given in Table 1 and 2.
Since the global B-attractor $K_{\text{global}}$ involves two-dimensional unstable manifolds of equilibria $S_{1,2}$, we have

$$\dim_L K_{\text{global}} = \dim_L K_{\text{global} B} = 2.8908...$$

Since the global B-attractor $K_{\text{global} B}$ in Fig. 3(c) involves two-dimensional unstable manifolds of equilibria $S_{1,2}$, we have

$$2 \leq \dim_H K_{\text{global} B} \leq \dim_L K_{\text{global} B}.$$ 

For the B-attractor $K_{B}$, the global attractor $K_{\text{global}}$, global B-attractor $K_{\text{global} B}$, in Fig. 4(b,c,d) we have

$$\dim_L K_{\text{global}} = \dim_L K_{\text{global} B} = \dim_L K_{B} = 2.8918...$$

Figure 6: Dynamics of the finite-time local Lyapunov dimensions for the time interval $t \in [0, 60]$: maximum on the grid of points (dark red), at the point $P_1 = (10, 60, 800) \in C_{\text{se,h}}$ (light red), at $P_2 = (-0.0074, -0.0997, 0)$ from 1D unstable manifold of $S_0$ (blue); at the equilibrium $S_0$ (green).
Since the global B-attractor $K_{\text{global}}$ in Fig. 4(d) involves one-dimensional unstable manifolds of equilibrium $S_0$, we have

$$1 \leq \dim_H K_{\text{global}} B \leq \dim_L K_{\text{global}} B.$$ 

Remark that the absorbing sets $B^v = B(687.5, 4, 0.0052)$ and $B^h = B(700, 4, 0.0052)$ involve all the considered attractors in Fig. 3 and Fig. 4, respectively. Thus, for the corresponding grid of points by estimation (21) with $S = I$, we get an estimate for any attractor $K$ in Fig. 3 (here the distance between grid points is 20):

$$\dim_H K \leq \dim_L K \leq \sup_{u \in B^v} d_{\text{LY}}^K \left( \{ \lambda_j(u) \}_{i=1}^n \right) \approx \sup_{u \in B^h_{\text{grid}}} d_{\text{LY}}^K \left( \{ \lambda_j(u) \}_{i=1}^n \right) = 2.982747..., \quad (51)$$

and for any attractor $K$ in Fig. 4

$$\dim_H K \leq \dim_L K \leq \sup_{u \in B^h} d_{\text{LY}}^K \left( \{ \lambda_j(u) \}_{i=1}^n \right) \approx \sup_{u \in B_{\text{grid}}} d_{\text{LY}}^K \left( \{ \lambda_j(u) \}_{i=1}^n \right) = 2.983037.... \quad (52)$$

![Figure 7: Dynamics of $d_{\text{LY}}^K \left( \{ \lambda_j(u(t, P_1)) \}_{i=1}^n \right)$ (red) and $d_{\text{LY}}^K \left( \{ \lambda_j(u(t, P_2)) \}_{i=1}^n \right)$ (blue) along the trajectories with initial data $P_1 = (10, 60, 800) \in C_{\text{grid}}^{\text{se}, P_1}$ and $P_2 = (-0.0074, -0.0097, 0)$.](image)

The above numerical experiments lead to the following important concluding remarks. While the Lyapunov dimension, unlike the Hausdorff dimension, is not a dimension in the rigorous sense [57, 88] (e.g. the Lyapunov dimension of a saddle point or a periodic orbit can be noninteger and has different values including those close to $n$), it gives an upper estimate of the Hausdorff dimension. The sets with noninterger Hausdorff dimension are referred as the fractal sets [89]. Let the attractor

$$\{ \lambda_j(u(t, P_1)) \}_{i=1}^n$$

self-excited attractor

hidden attractor

Figure 7: Dynamics of $d_{\text{LY}}^K \left( \{ \lambda_j(u(t, P_1)) \}_{i=1}^n \right)$ (red) and $d_{\text{LY}}^K \left( \{ \lambda_j(u(t, P_2)) \}_{i=1}^n \right)$ (blue) along the trajectories with initial data $P_1 = (10, 60, 800) \in C_{\text{grid}}^{\text{se}, P_1}$ and $P_2 = (-0.0074, -0.0097, 0)$. The Lyapunov dimension for different points, thus the maximum of the finite-time local Lyapunov dimension on the grid of point $t_{i=1}^{t_{T+1}} \lim_{u \to K_{\text{grid}}} \frac{\text{LE}_i(t, u)}{i=1} = \{ \text{LE}_i(u) \}_{i=1}$, if they exist and are the...
same for all \( u \in K \) (and therefore \( \dim L^K = d^{KY}_{L,1}(\{LE_i(u_0)\}_{i=1}^n) \) for any \( u_0 \in K \), the \textit{absolute} ones and wrote that such absolute values \textit{rarely exist}.

5. Conclusion and further steps

In this paper the Lyapunov dimension of attractors in the Glukhovsky-Dolzhansky fluid convection model has been studied by analytical and numerical methods. In studying we follow a rigorous approach to the definition of the Lyapunov dimension and justification of its computation by the Kaplan-Yorke formula, without using statistical physics assumptions. The exact Lyapunov dimension formula for the global attractors is obtained and peculiarities of the Lyapunov dimension estimation for self-excited and hidden attractors are discussed. A tutorial on numerical estimation of the Lyapunov dimension on the example of the Glukhovsky-Dolzhansky model is presented.

Acknowledgements

Authors would like to thank Alexander Gluhovsky, Professor of the Department of Earth & Atmospheric Sciences and Department of Statistics, Purdue University, USA, for the fruitful discussion and valuable comments on the low-order models. This work was supported by the Russian Science Foundation (14-21-00041).
