Mapping oral cancer research in South Africa

ABSTRACT
The aim of the present study was to review the scope of oral squamous cell carcinoma (OSCC) research in South Africa, including its epidemiology, diagnosis, associated risk factors and management. All publications relating to OSCC on the South African population were sought. A total of 72 studies were included and classified into seven categories; most studies were case reports or case series. Risk factors and epidemiology were the most investigated categories while early detection and diagnosis was the least explored. All the main ethnic groups in South Africa were investigated. The highest incidence of OSCC in South Africa was reported for males of mixed ancestry; there was a male predominance in all ethnic groups except for Asians. There is a high prevalence of OSCC in younger individuals in comparison with the global average. Future research about early detection and diagnosis, risk factors, premalignant lesions, management and disease progression is suggested. Educational programmes are necessary and should include schools and tertiary education institutions to reach adolescents and young adults.

INTRODUCTION
OSCC ranks amongst the ten most prevalent cancers in the world; being associated with high morbidity and mortality, it constitutes a public health problem. As in several low and middle-income countries, lack of access to oral health care can delay diagnosis of OSCC and ultimately decreases survival rates. It has been recognised that cancers in the oral cavity and oropharynx present wide geographical heterogeneity. In South Africa, OSCC derives from a wide geographical area. OSCC in South Africa is the fifth most common cancer in males and the tenth most common cancer in females. Globally, 6% of oral cancers occur before the age of 45; in South Africa, 7.3% of oral cancers occur in males in this age group, and 7.8% in females. Lifestyle-related factors like smoking, alcohol, betel nut and spices consumption, together with other risk factors such as the human papillomavirus (HPV) and persistent inflammation in the oral cavity, are associated with the aetiology of OSCC.

METHODS
This report draws on the Arksey and O’Malley methodological framework for scoping reviews. Inclusion criteria used to identify potential studies:

1. **Anatomical sites**: oral, oropharyngeal, or both.
2. **Fields of study**: premalignant and malignant lesions, leukoplakia, erythroplakia, combined leukoplakia/erythroplakia, proliferative verrucous hyperplasia, carcinoma-in-situ, verrucous carcinoma, and oral squamous cell carcinoma (OSCC).
3. **Study design**: laboratory studies, case reports, case series, case-control studies, cross-sectional studies (including diagnostic accuracy studies), surveys, cohort studies, randomised controlled trials (RCTs) and other clinical trials, screening studies (using Toluidine Blue, chemiluminescence, brush biopsy, and tissue fluorescence imaging) and qualitative studies.
4. **Population**: South African population samples. International multicentre studies where one or more sites in South Africa were included were also eligible.

ACRONYMS
- **HPV**: human papillomavirus
- **NCR**: National Cancer Registry
- **OSCC**: oral squamous cell carcinoma
- **RCT**: randomised controlled trials

South Africa, OSCC derives from a wide geographical area. OSCC in South Africa is the fifth most common cancer in males and the tenth most common cancer in females. Globally, 6% of oral cancers occur before the age of 45; in South Africa, 7.3% of oral cancers occur in males in this age group, and 7.8% in females. Lifestyle-related factors like smoking, alcohol, betel nut and spices consumption, together with other risk factors such as the human papillomavirus (HPV) and persistent inflammation in the oral cavity, are associated with the aetiology of OSCC.

The aim of the present paper is to map archived material of OSCC in South Africa, including research on its epidemiology, aetiology, pathology, diagnosis, associated risk factors and management. Results from this review could help in defining and refining knowledge and voids relating to OSCC research in South Africa.
Secondary research (e.g. literature reviews) as well as primary studies where the focus was on oral tumours of odontogenic origin, salivary gland origin, tumours of intra-osseous origin, lymphomas, Kaposi’s sarcoma and lesions of melanocyte origin were excluded. Studies on lip cancer were also excluded.

Identification of studies for inclusion
A Medline electronic search (accessed via PubMed) was performed in October 2012 and updated in January 2014 and 2017, according to the search terms displayed in Table 1. Furthermore, hand searching of reference lists of potentially eligible studies was performed during the screening and data extraction process. The heads of the departments of South African universities in the disciplines of Otolaryngology (eight departments), Oral Medicine and Periodontology (four departments), Oral Pathology (four departments), and Maxillofacial and Oral Surgery (three departments) were contacted via email and asked to send any additional studies that could have been missed by the electronic search.

Selection of studies and extraction of data
Two authors independently reviewed the titles from the electronic search results and selected potentially eligible studies. Disagreements were resolved by discussion until a consensus was reached. The articles sent by the heads of departments were screened for their eligibility.

The following data were extracted from the included articles: category (case reports & case series, prevalence & incidence, risk factors, early detection and diagnosis; premalignant lesions; treatment; and progression of disease); study period; study design, sample size, demographics (gender, age, ethnicity), aim/objectives and main findings. Missing data were described as ‘not reported’.

RESULTS
The search results and selection process are displayed in Figure 1. In summary, four-hundred-and-two articles were identified through the Medline search, of which 70 were identified as potentially eligible during the screening process. The 19 emails sent out to heads of departments resulted in 46 articles received, of which 22 were included as potentially eligible. Scrutiny of the full texts resulted in 72 studies that met the eligibility criteria. The included studies were classified into seven categories, as displayed in Table 2. Early detection and diagnosis, premalignant lesions and disease progression were the least investigated categories. The earliest included study included was performed in 1964 and the latest was performed in 2014. All the extracted data were summarised in Tables 3 to 10.

Figure 1: Flow diagram displaying the search results and selection process.
adults and elderly. All main ethnic groups in South Africa (Whites, Blacks, Asians and people with Mixed ancestry, also referred to as “Coloured”, according to the Population Registration Act n.30 of 1950, repealed in 1991[89]) have been investigated in relation to OSCC, which is important due to the potential influence of ethnicity on OSCC.

Several of the included studies lacked clear objectives; amongst those that explicitly stated the objectives, in many instances the design of the study was not ideal to address the objective. For the studies on risk factors for example, most were case series or cross-sectional, which offer limited information on the topic. Similarly, for the treatment category, only one out of the nine included studies was a RCT, which is the most suitable design to evaluate the efficacy of an intervention.[37]

Only one of the included studies was a randomised controlled trial (RCT). Due to the higher prevalence of OSCC among older people, most studies included

---

### Table 2: Categories of OSCC research

| Category                        | Number of studies |
|---------------------------------|-------------------|
| Case reports and case series    | 12                |
| Incidence and prevalence        | 12                |
| Risk factor                     | 21                |
| Early detection and diagnosis   | 3                 |
| Premalignant lesions            | 7                 |
| Treatment                       | 10                |
| Disease progression             | 7                 |

### Table 3: Studies in the category case reports and case series

| First author & year | Study period | Study design | Sample size | Gender | Age* | Ethnicity | Demographics | Aims/objectives | Findings |
|---------------------|--------------|--------------|-------------|--------|------|-----------|--------------|----------------|----------|
| De Waal 2008 80     | NR           | Case series  | 2           | M      | adults | NR        |              | To describe a case of OSCC of anterior mouth floor and dorsolateral tongue surface | The dentist should always be aware of changes in the oral mucosa, especially in high risk areas of the mouth in patients that smoke and/or consume alcohol. |
| De Waal 2008 35     | NR           | Case series  | 2           | M      | adults, elderly | NR |              | To describe two cases of oral leukoplakia | Identification and control of leukoplakia is necessary in order to decrease the risk of malignant transformation. |
| Dreyer 2010 11      | NR           | Case report  | 1 M         | elderly | NR |          |              | To describe a case of carcinoma of the gingiva and erosive lichen planus | This case emphasises the importance of thorough examination of the oral cavity in all patients. For any deviation from the normal, a biopsy should be performed immediately. |
| Stander 2013 12     | NR           | Case report  | 1 M         | adult  | NR |          |              | To describe a case of OSCC of the tongue | This case was not typical; although it was associated with smoking and alcohol use, the patient was younger than the average OSCC patient. |
| Padayachee 2012 13   | 2009-2011    | Case report  | 1 F         | adult  | NR |          |              | To describe a case proliferative verrucous leukoplakia | This case had a single area with a white benign lesion, which transformed into verrucous carcinoma in the absence of traditional risk factors. Clinicians must be aware of white lesions in older adults. |
| Padayachee 2010 14   | NR           | Case report  | 1 F         | adults | NR |          |              | To describe a case of OSCC of the gingiva related to teeth 31 and 41 | This unusual case was associated with HIV and mimicked a periodontal lesion that could have been mistaken by a periodontal abscess. |
| Mulwafu 2006 15      | NR           | Case series  | 2 F         | adults | Coloureds, Blacks |              |              | To describe 2 cases OSCC in patients with discoid lupus erythematosus (DLE) | DLE may have a role in the development of OSCC. |
| Nortjie 2005 16      | NR           | Case report  | 1 M         | adults | NR |          |              | To describe OSCC of anterior mouth floor - Radiological presentation of spread into mandible | Carcinomas in the mandible may result in paraesthesia, pathological fracture, bone erosion and eventual metastasis to regional lymph nodes. |
| Peck 2010 77         | NR           | Case series  | 2 F         | adults | NR |          |              | To describe two cases of OSCC on the dorso-lateral surface of tongue | OSCC have a variety of clinical presentations, and is not always associated with traditional risk factors of smoking and alcohol consumption. One patient was under 45 years. |
| Peck 2012 18         | NR           | Case report  | 1 M         | adults | NR |          |              | To describe a case of oral submucous fibrosis (OSF) and lichenoid interface mucositis | The rare dual lesion could be associated to areca nut or spices used by the patient. The tissue reaction could have been aggravated by the epithelial atrophy in OSF. |
| Feller 2006 19       | NR           | Case report  | 1 M         | adults | Asians** |          |              | To describe a case of leukoplakia | A rare case of proliferative verrucous leukoplakia is presented. |
| Mamabolo 2006 30     | NR           | Case report  | 1 M         | adults | NR |          |              | To describe a case of OSCC of the anterior mouth floor | Taking biopsy on chronic ulcers is critical to provide proper treatment, which is guided by the clinical stage of the disease. |

*Age refers to either elderly (>65 years old), adult (18 to 65 years old), adolescent (12 to 18 years old), or child (<12 years old)

**Asians include people from Indian descent • M = male; F = female; NR = not reported
| First author & year | Study period | Study design | Sample size | Demographics | Aims/objectives | Findings |
|---------------------|--------------|--------------|-------------|--------------|----------------|----------|
| Abram 2012<sup>18</sup> | 1997-2001    | Data from National Cancer Registry | 5470        | M+F          | All | Whites, Coloured, Black, Asian | To investigate the epidemiology of OSCC in South Africa from 1997-2001 | Prevalence of OSCC in subjects <45 years was higher in South Africa (7.3% for males and 7.8% for females), as compared to the global prevalence of 6%. The lifetime risk for developing OSCC and OPSCC is highest for coloured males and lowest for black females. |
| Hille 1996<sup>22</sup> | 1988-1991    | Data from National Cancer Registry | 5396        | M+F          | All | Whites, Coloured, Black, Asian | To present age standardized incidence rates of oral cancer in South Africa | From 1988-1991, 3.4% of all cancer cases in South Africa were oral cancers. The incidence of oral cancer in coloured men was the highest (13.13 per 100,000) of ethnic groups. Major educational programmes are needed. |
| Ndui 2011<sup>28</sup> | 1996-2002    | Data from National Cancer Registry | 9702        | M+F          | All | Whites, Coloured, Black, Asian | To present the epidemiology of OSCC in South Africa from 1996-2002 | The total number of OSCC over the 7-year period was 9702, the majority of it on the tongue. The male to female ratio was 1:3. The incidence rates were highest for coloured males. |
| Breytenbach 1980<sup>23</sup> | NR Cross Sectional | 265 | M+F | All | Coloured, Indian, Cape Malay | To determine the incidence of OSCC in the Natal African | The pattern of oral cancer in Cape Coloured resembles other ethnic groups in South Africa. |
| Dreyer 1977<sup>24</sup> | 1974-1976    | Cross Sectional | 722        | M+F          | All | Cape Malay | To determine the prevalence of leukoplakia among the Malay population of the Cape Malay | Leukoplakia was present in 7.2% of the population and smoking played a major role in most white lesions. |
| Schonland 1968<sup>25</sup> | 1964-1966    | Cross Sectional | 3174        | M+F          | adolescents, adults, elderly | Black | To determine cancer incidence in the Natal African | In the rural areas, incidence decreases with the degree of isolation from the urban areas. Results suggests that the differences found were not correlated to medical care. |
| Schonland 1969<sup>26</sup> | 1964-1968    | Cross Sectional | NR          | M+F          | adolescents, adults, elderly | Blacks, Indian | To describe OSCC in the Natal African and Indian | Cancer incidence in South Africans from Durban (both sexes) is as high as for most western countries. Indian males have a low overall cancer incidence. |
| Schonland 1969<sup>27</sup> | NR Cross Sectional | 99 | M+F | adolescents, adults, elderly | Black | To investigate the incidence of oropharyngeal cancers | Several cases of OSCC were included and the prevalence differed in the population groups. |
| Walker 1999<sup>28</sup> | NR Cross Sectional | NR | M+F | All | Asians** | To learn of the current pattern of cancer in the descendants of people who emigrated from India to Durban, South Africa | The main finding was the lower percentage of oral and oropharyngeal cancers in South African Indians in both sexes, as compared to Indian subjects. |
| Ayo-Yusuf 2013<sup>29</sup> | 1992-2001    | Data from National Cancer Registry | 16844       | M+F          | All | Whites, Blacks, Asians, Coloureds | To examine the trends and ethnic disparities in oral and oro-pharyngeal cancers in South Africa during the period 1992 – 2001 | Oro-pharyngeal cancers had higher incidence rates for coloured South Africans and lower among Blacks. |
| Alimi 1985<sup>30</sup> | 1971-1980    | Case Series | 358         | M+F          | adults, elderly | Black | Age-specific and age-standardized incidence rates for intraoral squamous cell carcinoma in Blacks on the Witwatersrand, South Africa | The age-standardised incidence rates of OSCC are relatively high for South African Black males and low for South African Black females when compared to other countries. |
| Shear 1970<sup>31</sup> | 1965-1968    | Cross Sectional | M+F | adults, elderly | Whites, Black | To investigate the distribution of oral cancer in Africans and Whites in Johannesburg | Oral cancer was more prevalent among males. More African males under 40 years had oral cancer than White males. |

*Age refers to either elderly (>65 years old), (adult (18 to 65 years old), adolescent (12 to 18 years old), or child (<12 years old)

**Asians include people from Indian descent • M = male; F = female; NR = not reported
**Table 5: Studies in the category risk factors**

| First author & year | Study period | Study design | Sample size | Demographics | Aims/objectives | Findings |
|---------------------|--------------|--------------|-------------|--------------|----------------|----------|
| Chandran 2005<sup>11</sup> | NR           | Case Control | 134 M+F     | adults, elderly, Whites, Coloured, Black, Asian | To determine the risk of intraoral cancer associated with tobacco and alcohol | Patients who use tobacco and alcohol had seven times more risk to develop oral cancer, as compared non-smokers and non-alcohol consumers. |
| Darling 1993<sup>31</sup> | NR           | Cross Sectional | 579 M+F    | adults, Whites, Coloured | To determine the effects of cannabis smoking on oral soft tissues | Cannabis users presented higher incidence of leukoedema, dry mouth and traumatic ulcers. |
| Van Rensburg 1995<sup>24</sup> | NR           | Case Series | 105 M+F     | adults, elderly, Black | Detection of Epstein-Barr Virus (EBV) in OSCC in a black African population sample | There was no evidence for a direct role of EBV in the process of malignant transformation of intraoral epithelial cells. |
| Bissessur 2009<sup>35</sup> | NR           | Cross Sectional | 101 M+F    | adults, Indian | To determine areca nut chewing habits in Durban | Areca nut/chewing gum is a common habit among Indians from Durban, South Africa, among younger age groups. |
| Seedat 1988<sup>35</sup> | 1981-1983    | Cross Sectional | 2058 M+F   | adolescents, adults, elderly, Indian | To determine the prevalence of betel-nut chewing and submucous fibrosis in Durban | Betel-nut chewing is very prevalent among South African Indians (5%) and can result in serious health problems, including permanent trismus and oral cancer. |
| Van Wyk 1993<sup>27</sup> | 1983-1989    | Case Series | 143 M+F     | adolescents, adults, elderly, Indian | To investigate the association of areca nut chewing and OSCC in South African Indians | Areca nut use (alone or associated with tobacco) plays a role in the development of OSCC. Eliminating this habit can decrease the risk for OSCC in 89-91%. |
| Schonland 1969<sup>39</sup> | NR           | Cross Sectional | 99 M+F     | adults, elderly, Indian | Upper alimentary tract cancer in Natal Indians | Cancers of the mouth and oesophagus are more prevalent in Indian females than males, which can be related to the higher addiction to betel-chewing amongst females. |
| Van Rensburg 1995<sup>23</sup> | NR           | Case Series | 66 M+F      | adults, elderly, Black | Detection of Human Papilloma Virus (HPV) DNA with in situ hybridisation in OSCC in a rural black population | HPV is of limited importance in OSCC carcinogenesis in the studied population. |
| Boy 2006<sup>42</sup> | 1998-2003    | Case Series | 59 M+F      | adults, elderly, Whites, Coloured, Black, Asian | To investigate the detection of HPV in the oropharynx using real time polymerase chain reaction | There was no correlation between HPV detection and OSCC. |
| Fleming 1982<sup>41</sup> | 1965-1979    | Cross Sectional | 890 M+F    | adolescents, adults, elderly, Whites, Blacks | To establish whether there are differences in the distribution of oral carcinoma between Blacks and whites | OSCC was more prevalent in Black subjects under 50 years of age as compared to white subjects. |
| Hemmer 2008<sup>42</sup> | NR           | Case Series | 10 NR      | NR | NR | Is there correlation between ploidy by flow cytometry and chromosome 3 aberration in OSCC | Structural rearrangements involving the long arm of chromosome 3 are frequent in OSCC. |
| Davidson 2014<sup>43</sup> | 1995-1999    | Cross Sectional | 125 M     | adults, NR | To examine the presence of human papilloma virus in sample of South African men. | None of the patients who presented oral lesions were positive to HPV. |
| Pacella-Norman 2002<sup>44</sup> | 1986-1995    | Case Series | 125 M+F    | adults, elderly, Blacks | To provide recent estimates of the relative importance of some of the suspected risk factors for oesophageal, lung, oral, and laryngeal cancers | Tobacco was the leading risk factor for all cancers. |
| Postma 2002<sup>45</sup> | 1998-2003    | Case Series | 53 M+F     | NR | NR | To investigate whether the human papillomavirus is a mutual aetiological agent in oral and cervical squamous cell carcinoma | The results support the idea of systemic susceptibility and infection through a common agent, such as HPV, which could contribute to development of SCC. |
| Van Heerden 2002<sup>46</sup> | NR           | Case Series | 53 M+F     | NR | NR | To investigate the suitability of paraffin-embedded material to predict the metastatic potential of OSCC | DNA aneuploidy could predict the metastatic potential of OSCC through DNA flow cytometry from paraffin-embedded primary lesions of OSCC. |
| Van Heerden 1999<sup>47</sup> | NR           | Case Series | 32 NR      | NR | NR | Immunohistochemical evaluation of Fhit protein expression in OSCC | Expression of Fhit protein was altered in OSCC, which suggests that the inactivation of Fhit can play a role in oral carcinogenesis. |
| Van Heerden 2001<sup>48</sup> | NR           | Case Series | 17 NR      | NR | NR | To investigate the role of Fhit in oral carcinogenesis | Around 60% of OSCC have no expression of Fhit protein, which can play a role in the initiation of OSCC. |
| Van Rensburg 1998<sup>49</sup> | NR           | Case Series | 55 NR      | adults, elderly, Black | To determine p53 mutation profile in OSCC of a Black African sample | p53 mutations seem to play a role in oral carcinogenesis. The unique distribution of the mutations suggested different responses to etiologic agents. |
| Van Heerden 1995<sup>50</sup> | NR           | Case Series | 120 M+F    | adults, elderly, Whites, Black | To investigate the prevalence of Epstein-Barr Virus (EBV) in OSCC in young patients | A possible role of EBV virus in the development of OSCC cannot be excluded, although it does not influence age distribution. |
| Van Rensburg 1996<sup>51</sup> | NR           | Case Series | 146 M+F    | adults, elderly, Black | To investigate the presence of HPV DNA in OSCC from an African population sample | HPV is not an etiologic factor in the development of OSCC in the studied population. |
| Van Heerden 1998<sup>52</sup> | NR           | Case Series | 110 NR     | NR | Blacks | Correlation between p53 gene mutation, p53 protein labelling and Proliferating Cell Nuclear Gene (PCNA) expression in OSCC | Overexpression of p53 protein was not associated with mutations in the p53 gene. |
**Asians include people from Indian descent • M = male; F = female; NR = not reported**

DISCUSSION

Case reports/case series
The several case reports and case series highlighted the importance of the biopsy for abnormal lesions in the oral cavity in order to avoid delays in the diagnosis of OSCC. Most cases were associated with tobacco use and alcohol consumption; however, a few cases of OSCC were reported in younger patients in the absence of traditional risk factors. Reports on oral cancer in HIV-infected and discoid lupus erythematosus patients suggest a possible role for these conditions in relation to OSCC. With the alarming statistics for HIV in South Africa, 12.7% of the population is HIV-positive (Government Statistical Release 2016); the development of non-AIDS related cancers requires further attention.

Prevalence and incidence
In South Africa, the National Cancer Registry (NCR) compiles pathology-based data on cancer in the country. The most recent studies on prevalence and incidence of oral cancer in South Africa relies on data extracted from the NCR database. Globally, oral cavity and oropharynx cancers combined account for approximately 5% of all cancers in males and 2% of all cancers in females; the number of new cases per year for both genders is estimated at 310,000. In South Africa, from 1997-2001, 5% of all cancers in males and 0.6% of all cancers in females were oral cancers; 0.6% and 0.1% were cancers in the oropharynx of males and females, respectively.

The average age standardized incidence rate (ASIR) for oral cancer in South Africa from 1996-2001 was 6.2/100,000/year for men and 1.6/100,000/year for women. The combined ASIR for both genders was 4.5/100,000/year, which is not far from the global average ASIR of 5.1/100,000/year from the Globocan database.

Differences among ethnic groups were observed, with Coloured males having the highest ASIR for oral cancer (10.2/100,000/year), followed by white males (6.9/100,000/year). Asian women had the highest ASIR amongst females (3.4/100,000/year), followed by Coloured and White women (both 2.8/100,000/year). The only ethnic group where females had higher ASIR than males was the Asian group. In subjects under 45 years of age, there was no male prevalence.

The majority of oral cancers were diagnosed at the end of the sixth decade; the population average age at time of diagnosis was 57.8 years. In South Africa, the incidence of cancers in the oral cavity and oropharynx in males (7.3%) and females (7.8%) younger than 45 years is higher than the global average (6%). Rural populations seem to present lower incidence of OSCC as compared with urban groups.

Oral cancer in Sub-Saharan Africa presents estimated mortality rate of 2.8/100,000/year for males and of 1.0/100,000/year for females for cancer of the lip and oral cavity combined. A global estimate from the US for the 5-year relative survival rates for oral cancer is based on the clinical stage at diagnosis, with 82% for localized lesions, 52% for regional lymph node involvement and 27% for patients with metastasis. It must be pointed out that, since only cancers diagnosed histologically are included in the NCR, the real burden of oral cancer in South Africa can be worse than hitherto reported.

Risk factors
Traditional risk factors such as smoking and alcohol consumption play a crucial role in the aetiology and pathogenesis of OSCC worldwide. Globally, oral cancer is more prevalent in males and so is smoking; in South Africa the gap among genders is large, while 32% of adult men smoke, only 8% of adult women are smokers.

The use of potentially carcinogenic leaf products such as areca nut, associated or not with tobacco, adds to the complexity of aetiological factors for oral cancer in South Africa. The habit of chewing areca nut can maybe explain the higher prevalence of oral cancer in female South Africans of Indian heritage as compared to male Indian South Africans. It has been reported that up to 93% of adult South Indian African women chew areca nut/quid.

The potential role of infection with HPV16 and 18 infection in OSCC has been investigated worldwide, especially in non-smoker younger patients. Neither HPV nor Epstein-Barr virus were associated with OSCC in South African subjects. One case series investigated alterations in chromosome 3 in relation to OSCC and suggested that mutations in the short arm of chromosome 3 may play a role in the progression of OSCC.

Globally, low socio economic status has been associated with increased odds ratio for development of oral cancer (OR up to 2.4), measured as low income, educational level and social class. Furthermore, a pooled analysis of 16 studies showed that each portion of fruit or vegetables consumed per day decreases the risk for oral cancer (OR 0.5). In a country with much inequity such as South Africa, it is surprising that no study has evaluated the role of low socio economic status and dietary deficiency for oral cancer.

Early detection and diagnosis, premalignant lesions and disease progression
Despite advances in research and surgical techniques, the 5-year survival rate for OSCC remains low, with a rough estimate of 50%. The high morbidity and mortality rates emphasize the importance of screening programmes and techniques for early detection of malignancy. Although exfoliative cytology has been investigated as a prescreening alternative, the gold standard for diagnosis of cancer of the oral cavity and oropharynx remains the biopsy. Visual examination is still the best screening tool; guidelines from the American Dental Association suggest that cytology can be useful for patients with suspicious lesions that refuse to undergo biopsy.

Leukoplakia is the most common premalignant lesion, the overall risk for malignant transformation in oral leukoplakia lesions is estimated at 2%. The majority of leukoplakia (80%) reported in South Africa affects white subjects. Oral submucous fibrosis is another recognized premalignant condition, with an estimated malignancy transformation rate of 3.7%. Chewing of areca nut, a common habit among Indian and Indian-descendant women, is a significant
risk factor for developing oral submucous fibrosis. More studies are necessary to better understand the carcinogenesis of those premalignant lesions.

It is estimated that in approximately 40% of patients with OSCC, the disease progresses through metastases in cervical lymph nodes, which worsen prognosis and survival rates. Submandibular and auxiliary lymph nodes are rarely affected, but should be examined routinely. Studies have suggested that DNA flow cytometry can help identify the risk for metastasis in primary OSCC tumours. Understanding the progression of the disease and its metastatic potential can help improve survival rates.

The search for prognostic markers of disease progression for OSCC in South African subjects has not yet been successful according to studies on the expression of E-cadherin and b-catenin. Fhit protein has been investigated as a potential prognostic factor, since the tumour suppressant FHT gene seems to be inactivated in severe dysplastic OSCC lesions. Prognosis of tongue cancer has been reported as worse when this protein is under expressed; however the clinical application of this finding is still to be determined.

Treatment

Surgical techniques for oral cancer treatment have been the primary focus of studies on OSCC management in South African subjects, highlighting that most lesions are diagnosed at a late stage. Surgery is the main treatment strategy for oral cancer patients worldwide, especially in advanced stages. A study from 1992 reported a 50% survival rate at 3 years and 25% at 5 years for South Africans submitted to major surgery for OSCC.

Radiotherapy is usually used as an adjunctive treatment after surgery for advanced lesions. Chemotherapy has not been commonly used for oral cancer treatment, however, there has been a trend for its use combined with surgery and radiation in advanced or recurrent cases. The use of molecular targeted drugs holds promise on less debilitating treatment options for OSCC patients worldwide.

CONCLUSIONS

OSCC is a significant problem in South Africa, resulting in morbidity and mortality. Ethnic and gender variations are present, with males of mixed ancestry, having the highest incidence rate of OSCC in the country. Smoking and alcohol consumption are strong risk factors for OSCC in the general population. The prevalence of OSCC in young subjects (<45 years) in South Africa is higher than the global average and not always associated with traditional risk factors.

Generally, there is a paucity of information on premalignant lesions, early diagnosis, traditional and non-traditional risk factors, disease progression and management of cancers of the oral cavity and oropharynx in South Africa. Although there seems to be enough information on the epidemiology of OSCC in the country, an underestimation of the incidence and prevalence cannot be excluded.

Various studies mention the need for educational programmes and public health policies targeting risk factors and early identification of lesions, which ideally should translate into less invasive treatment, better quality of life and lower mortality rates. Educational programmes should include schools and tertiary education institutions to reach adolescents and young adults.
