Abstract

We present two-loop results for the quark condensate in an external magnetic field within chiral perturbation theory using coordinate space techniques. At finite temperature, we explore the impact of the magnetic field on the pion-pion interaction in the quark condensate for arbitrary pion masses and derive the correct weak magnetic field expansion in the chiral limit. At zero temperature, we provide the complete two-loop representation for the vacuum energy density and the quark condensate.

1 Introduction

The quark condensate – order parameter of spontaneous chiral symmetry breaking – is a crucial quantity in particle physics. It comes with no surprise that the relevant literature is extensive. Here we focus on the properties of the quark condensate in an external constant magnetic field. Our calculation within the framework of chiral perturbation theory (CHPT) goes up to two-loop order, but in contrast to the available CHPT-studies – see Refs. [1–10] – we use a coordinate-space representation for the pion propagators and the associated kinematical functions. Other references, also dealing with the quark condensate in a magnetic field, are based upon lattice QCD [11–20], feature analytical studies relying on the Nambu-Jona-Lasinio model [21–27], or comprise yet other models and methods [28–35].

In a recent article, Ref. [36], the present author has pointed out that – in the chiral limit – the two published one-loop series for the finite-temperature quark condensate
in a weak magnetic field, independently derived by different authors, are erroneous. The proper series at one-loop order has been established in Ref. [36] – one of our goals in the actual study is to review the situation at two-loop order. Indeed, errors also occur here. We clarify the situation by providing the correct weak magnetic field expansion of the finite-temperature quark condensate in the chiral limit. One of the advantages of our coordinate-space approach is that it allows for a transparent derivation of the various limits that have to be taken in the calculation: chiral limit ($M \rightarrow 0$) and weak magnetic field limit ($|qH| \ll T^2$).

Apart from straightening these issues, we also investigate the impact of the magnetic field on the pion-pion interaction in the quark condensate for arbitrary pion masses. At finite temperature, the interaction constitutes up to ten percent as compared to the leading noninteracting pion gas contribution, and is most pronounced in the chiral limit. When the magnetic field increases, the finite-temperature quark condensate (sum of one- and two-loop contribution at fixed temperature and pion mass) grows monotonically. The effect is again most pronounced in the chiral limit.

Using the dressed pions as pertinent degrees of freedom, the low-temperature series of the quark condensate is characterized by a $T^2$-contribution that refers to the dressed but non-interacting pions, while interaction effects emerge at order $T^4$. In the chiral limit and in weak magnetic fields, the series at order $T^2$ – organized by the expansion parameter $\epsilon = |qH|/T^2$ ($q$ is the electric charge of the pion) – involves a leading square-root term $\propto \sqrt{\epsilon}$, a term linear in $\epsilon$, followed by a half-integer power $\epsilon^{3/2}$ and a logarithmic contribution $\epsilon^2 \ln \epsilon$. The remaining contributions involve even powers of $\epsilon$. At order $T^4$ the series exhibits the same structure, with the exception that a term linear in $\epsilon$ is absent – in contrast to what has been reported in the literature.

Finally, we provide the two-loop representation for the QCD vacuum energy density and the zero-temperature quark condensate. The representation involves nonanalytic contributions in the form of logarithms, as well as Gamma and Polygamma functions that depend nontrivially on the ratio between magnetic field and pion mass. In contrast to previous studies we provide the full two-loop representation – not merely the terms that are induced by the nonzero magnetic field.

The article is organized as follows. The two-loop CHPT evaluation is briefly reviewed in Sec. 2 to set the basis for the subsequent analysis. In Sec. 3 we explore the quark condensate at finite and zero temperature for arbitrary pion masses – in particular also for the physical pion masses – in presence of a magnetic field. In the same section we furthermore compare our findings with the literature and point out errors in the published results. Finally, Sec. 4 contains our conclusions. More technical issues are presented in three appendices. In Appendix A we discuss in detail the two-loop CHPT evaluation at zero temperature. While Appendix B is devoted to the chiral limit in nonzero magnetic fields at $T=0$, in Appendix C we consider the same situation at finite temperature which boils down to an analysis of the various kinematical functions required.
Figure 1: Chiral perturbation theory diagrams for the QCD free energy density up to order $p^6$. Vertices from $L^2_{\text{eff}}$ (filled circles), as well as vertices from $L^4_{\text{eff}}$ and $L^6_{\text{eff}}$ (denoted by the numbers 4 and 6) contribute. The lines refer to the thermal pion propagators.

2 Chiral Perturbation Theory Evaluation

The relevant low-energy excitations in two-flavor chiral perturbation theory are the three pions that are incorporated in the SU(2) matrix $U(x)$ as

$$U(x) = \exp(i\tau^i \pi^i(x)/F), \quad i = 1, 2, 3.$$  \hspace{1cm} (2.1)

Here $\tau^i$ are the Pauli matrices and $F$ stands for the tree-level pion decay constant. While $\pi^0$ describes the neutral pion, the charged pions correspond to the linear combinations

$$\pi^\pm = \frac{1}{\sqrt{2}}(\pi^1 \pm i\pi^2).$$  \hspace{1cm} (2.2)

The Euclidean leading-order (order $p^2$) effective Lagrangian is given by

$$L^2_{\text{eff}} = \frac{1}{4}F^2Tr\left[(D_\mu U)^\dagger(D_\mu U) - M^2(U + U^\dagger)\right],$$  \hspace{1cm} (2.3)

where $M$ is the tree-level pion mass. In the covariant derivative,

$$D_\mu U = \partial_\mu U + i[Q, U]A_{\mu}^{EM},$$  \hspace{1cm} (2.4)

the quantity $Q$ is the charge matrix of the quarks, i.e., $Q = \text{diag}(2/3, -1/3)e$, while the magnetic field $H$ enters via the gauge field $A_{\mu}^{EM} = (0, 0, -Hx_1, 0)$. As illustrated in Fig. 1, a two-loop calculation of the free energy density in addition involves the subleading pieces $L^4_{\text{eff}}$ and $L^6_{\text{eff}}$ of the effective Lagrangian.

The set of terms proportional to four pion fields generated by the leading piece

\footnote{For reviews of chiral perturbation theory see, e.g., Refs. [37, 38].}

\footnote{Although the Pauli matrix associated with the neutral pion is $\tau^3$, we will denote the neutral pion field as $\pi^0$ in view of its zero charge.}
$\mathcal{L}_{\text{eff}}^2$ – as required for the evaluation of the two-loop diagram 6A – are

\[
\mathcal{L}_{\{4\}}^2 = \frac{1}{3F^2} \pi^0 \partial_\mu \pi^0 \left( \partial_\mu \pi^+ \pi^- + \partial_\mu \pi^- \pi^+ \right) - \frac{1}{3F^2} \partial_\mu \pi^0 \partial_\mu \pi^0 \pi^+ \pi^- \\
- \frac{1}{3F^2} \pi^0 \partial_\mu \pi^0 + \frac{1}{3F^2} \pi^+ \pi^- \partial_\mu \pi^- + \partial_\mu \pi^- \pi^+ + \partial_\mu \pi^+ \pi^- \right). 
\]

(2.5)

Other pieces from $\mathcal{L}_{\text{eff}}^2$ needed for our calculation are terms with two (diagram 4A) or zero (diagram 2) pion fields,

\[
\mathcal{L}_{\{2\}}^2 = \frac{1}{2} \partial_\mu \pi^0 \partial_\mu \pi^0 + \partial_\mu \pi^+ \partial_\mu \pi^- + \frac{1}{2} M^2 \pi^0 \pi^0 + M^2 \pi^+ \pi^-,
\]

\[
\mathcal{L}_{\{0\}}^2 = -F^2 M^2.
\]

(2.6)

As for the subleading piece $\mathcal{L}_{\text{eff}}^4$, we use the representation given in Eq. (D.2) of Ref. [38]. The relevant terms for our calculation are those that contain two (diagram 6B) or zero (diagram 4B) pion fields,

\[
\mathcal{L}_{\{2\}}^4 = l_3 M^4 \frac{1}{F^2} \pi^0 \pi^0 + 2l_3 M^4 \frac{1}{F^2} \pi^+ \pi^- + (4l_5 - 2l_6) \frac{|qH|^2}{F^2} \pi^+ \pi^-,
\]

\[
\mathcal{L}_{\{0\}}^4 = -(l_3 + h_1) M^4 + 4h_2 |qH|^2.
\]

(2.7)

The quantities $l_3, l_5, l_6, h_1, h_2$ are next-to-leading order (NLO) low-energy effective constants.

Finally, following Ref. [39], the terms from $\mathcal{L}_{\text{eff}}^6$ contributing to the tree-level diagram 6C read

\[
\mathcal{L}_{\{0\}}^6 = -16(c_{10} + 2c_{11}) M^6 - 8c_{34} M^2 |qH|^2,
\]

where $c_{10}, c_{11}, c_{34}$ are next-to-next-to-leading order (NNLO) low-energy effective constants.

It is convenient to divide the free energy density into two pieces as

\[
z = z_0 + z^T,
\]

(2.9)

where $z_0$ contains all $T=0$ contributions (vacuum energy density), and $z^T$ involves the finite-temperature part – both terms depend on the magnetic field. Before addressing the $T=0$ case, we quote the result for the finite-temperature piece which has been derived within the CHPT coordinate-space approach up to two-loop order in Ref. [40]:

\[
z^T = -g_0(M_{\pi}^0, T, 0) - \frac{1}{2} g_0(M_{\pi}^0, T, 0) - \tilde{g}_0(M_{\pi}^\pm, T, H)
+ \frac{M^2}{2F^2} g_1(M_{\pi}^0, T, 0) g_1(M_{\pi}^0, T, 0) - \frac{M^2}{8F^2} \left\{ g_1(M_{\pi}^0, T, 0) \right\}^2
+ \frac{M^2}{2F^2} g_1(M_{\pi}^0, T, 0) \tilde{g}_1(M_{\pi}^\pm, T, H) + \mathcal{O}(p^8).
\]

(2.10)
The kinematical Bose functions are defined as

\[ g_0(M, T, 0) = T^4 \int_0^\infty d\rho \rho^{-3} \exp \left( -\frac{M^2}{4\pi T^2} \rho \right) \left[ S\left( \frac{1}{\rho} \right) - 1 \right], \]

\[ g_1(M, T, 0) = \frac{T^2}{4\pi} \int_0^\infty d\rho \rho^{-2} \exp \left( -\frac{M^2}{4\pi T^2} \rho \right) \left[ S\left( \frac{1}{\rho} \right) - 1 \right], \]

\[ \tilde{g}_0(M_{\pi}^\pm, T, H) = \frac{T^2}{4\pi} |qH| \int_0^\infty d\rho \rho^{-2} \left( \frac{1}{\sinh(|qH|\rho/4\pi T^2)} - \frac{4\pi T^2}{|qH|\rho} \right) \]
\[ \times \exp \left( -\frac{(M_{\pi}^\pm)^2}{4\pi T^2} \rho \right) \left[ S\left( \frac{1}{\rho} \right) - 1 \right], \]

\[ \tilde{g}_1(M_{\pi}^\pm, T, H) = \frac{1}{16\pi^2} |qH| \int_0^\infty d\rho \rho^{-1} \left( \frac{1}{\sinh(|qH|\rho/4\pi T^2)} - \frac{4\pi T^2}{|qH|\rho} \right) \]
\[ \times \exp \left( -\frac{(M_{\pi}^\pm)^2}{4\pi T^2} \rho \right) \left[ S\left( \frac{1}{\rho} \right) - 1 \right], \] (2.11)

and \( S(z) \) stands for the Jacobi theta function,

\[ S(z) = \sum_{n=-\infty}^{\infty} \exp(-\pi n^2 z). \] (2.12)

Note that \( \tilde{g}_0 \) and \( \tilde{g}_1 \) explicitly depend on the magnetic field through the hyperbolic sine and that they involve the mass \( M_{\pi}^\pm \), i.e., the masses of the charged pions in a magnetic field given by

\[ (M_{\pi}^\pm)^2 = M_{\pi}^2 + \frac{T_6 - T_5}{48\pi^2} |qH|^2. \] (2.13)

The mass \( M \) in \( g_0 \) and \( g_1 \), according to Eq. (2.10), can either represent \( M_{\pi}^\pm \) or \( M_{\pi}^0 \), where the latter is the mass of the neutral pion in a magnetic field,

\[ (M_{\pi}^0)^2 = M_{\pi}^2 + \frac{M^2}{F^2} K_1, \] (2.14)

and \( K_1 \) denotes the integral

\[ K_1 = \frac{|qH|}{16\pi^2} \int_0^\infty d\rho \rho^{-1} \exp \left( -\frac{M_{\pi}^2}{|qH|^2} \rho \right) \left( \frac{1}{\sinh(\rho)} - \frac{1}{\rho} \right). \] (2.15)

The kinematical functions \( g_0 \) and \( g_1 \) hence implicitly depend on the magnetic field through the neutral and charged pion masses. Finally, the mass \( M_{\pi} \) is the renormalized NLO pion mass in zero magnetic field,

\[ M_{\pi}^2 = M^2 - \frac{7}{32\pi^2} \frac{M^4}{F^2} + O(M^6). \] (2.16)
The quantities $\mathcal{I}_3, \mathcal{I}_5, \mathcal{I}_6$ are renormalized NLO low-energy effective constants – details are provided in Appendix A.1.

We now address the zero-temperature part in the free energy density. Apart from the temperature-independent tree-level graphs 2, 4B and 6C, we also have $T=0$ contributions from the loop graphs. This is because the thermal propagators for the pions,

$$G^\pm(x) = \sum_{n=-\infty}^{\infty} \Delta^\pm(\vec{x}, x_4 + n\beta),$$

$$G^0(x) = \sum_{n=-\infty}^{\infty} \Delta^0(\vec{x}, x_4 + n\beta), \quad \beta = \frac{1}{T},$$

contain a zero-temperature piece associated with $n=0$. In Appendix A.2 we process these $T=0$ contributions and show that all UV-divergences cancel. The final result for the renormalized vacuum energy density at order $p^6$ then amounts to

$$z_0^{[6]} = \frac{3\mathcal{I}_3(\overline{\mathcal{I}}_{10} + 2\overline{\mathcal{I}}_{11})}{1024\pi^4} \frac{M^6}{F^2} - \frac{(\overline{\mathcal{I}}_6 - \overline{\mathcal{I}}_5)\overline{\mathcal{I}}_{34}}{768\pi^4} \frac{|qH|^2 M^2}{F^2} - \frac{\mathcal{I}_3 M^4}{32\pi^2} \frac{1}{F^2} K_1 + \frac{(\overline{\mathcal{I}}_6 - \overline{\mathcal{I}}_5)}{48\pi^2} \frac{|qH|^2}{F^2} K_1. \quad (2.17)$$

The quantities $\mathcal{I}_i$ and $\overline{\mathcal{I}}_i$ are the renormalized NLO and NNLO effective constants, defined in Appendix A.1.

The full vacuum energy density also includes the zero-temperature pieces of order $p^4$ and $p^2$,

$$z_0 = z_0^{[6]} + z_0^{[4]} + z_0^{[2]},$$

which are (see Ref. [36] for $z_0^{[4]}$),

$$z_0^{[4]} = \frac{M^4}{64\pi^2} \left( \mathcal{I}_3 - 4\overline{h}_1 - \frac{3}{2} \right) + \frac{|qH|^2}{96\pi^2} \left( \overline{h}_2 - 1 \right) - \frac{|qH|^2}{16\pi^2} \int_0^\infty d\rho \rho^{-2} \left( \frac{1}{\sinh(\rho)} - \frac{1}{\rho} + \frac{\rho}{6} \right) \exp \left( - \frac{M^2}{|qH|^2 \rho} \right),$$

$$z_0^{[2]} = -F^2 M^2. \quad (2.20)$$

The subleading contributions $z_0^{[4]}$ and $z_0^{[6]}$ as displayed above, i.e., the renormalized expressions, are independent of the renormalization scale $\mu$. This is a nontrivial consistency check of our calculation. We now turn to the quark condensate which is the main subject of the present investigation.

---

3To the best of our knowledge, the complete CHPT two-loop representation for the QCD vacuum energy density – containing magnetic-field dependent as well as $H$-independent terms – is not available in the literature.
3 Quark Condensate in a Magnetic Field

The quark condensate is given by the derivative of the free energy density with respect to the quark mass

\[ \langle \bar{q}q \rangle = \frac{dz}{dm}. \]  

(3.1)

At zero temperature it corresponds to the vacuum expectation value

\[ \langle 0|\bar{q}q|0 \rangle = \frac{dz_0}{dm} = -\frac{\langle 0|\bar{q}q|0 \rangle_0}{F^2} \frac{dz_0}{dM^2}. \]  

(3.2)

Note that we have used the leading-order Gell-Mann–Oakes–Renner relation

\[ M^2 = -\frac{m}{F^2} \langle 0|\bar{q}q|0 \rangle_0, \]  

(3.3)

where the quantity \( \langle 0|\bar{q}q|0 \rangle_0 \) is the quark condensate at \( T=0 \) (and zero magnetic field) in the chiral limit – as indicated by the lower index ”0”. The purely finite-temperature part in the quark condensate amounts to

\[ \langle \bar{q}q \rangle^T = -\frac{dP}{dm} = \frac{\langle 0|\bar{q}q|0 \rangle_0}{F^2} \frac{dP}{dM^2}. \]  

(3.4)

Up to the sign, the pressure is nothing but the finite-temperature piece in the free energy density,

\[ P = -z^T. \]  

(3.5)

In the representation of \( z^T \), Eq. (2.10), we have used the NLO renormalized pion mass \( M_\pi \) instead of \( M \). The connection between the two quantities is given by Eq. (2.16). For the quark condensate we then obtain

\[ \langle \bar{q}q \rangle = \frac{\langle 0|\bar{q}q|0 \rangle_0}{F^2} \left\{ -\frac{dz_0}{dM^2} + \frac{dP}{dM^2} \right\} \left( 1 - \frac{M^2}{32\pi^2 F^2} (2\overline{l} - 1) \right). \]  

(3.6)

In the parenthesis we have replaced \( M^2 \) by \( M_\pi^2 \) which is legitimate at the order we are operating.

It should be pointed out that the zero-temperature quark condensate at order \( p^4 \), according to Eq. (2.20), involves the NLO effective constant \( h_1 \) which depends on the renormalization convention (see Ref. [41]). No such ambiguities due to NLO effective constants \( h_i \) are introduced in the zero-temperature quark condensate at order \( p^6 \), according to Eq. (2.18). Likewise, the finite-temperature part of the quark condensate is also free of such renormalization ambiguities.

\[ ^4 \text{Throughout the study we work in the isospin limit } m = m_u = m_d. \]
### 3.1 Finite-Temperature Quark Condensate

In order to make powers of temperature in the quark condensate manifest, instead of operating with the Bose functions $g_r$ and $\tilde{g}_r$, we now work with the dimensionless functions $h_r$ and $\tilde{h}_r$ defined as

$$h_0 = \frac{g_0}{T^4}, \quad \tilde{h}_0 = \frac{\tilde{g}_0}{T^4}, \quad h_1 = \frac{g_1}{T^2}, \quad \tilde{h}_1 = \frac{\tilde{g}_1}{T^2}, \quad h_2 = g_2, \quad \tilde{h}_2 = \tilde{g}_2.$$  

(3.7)

With the expression for $z^T$, Eq. (2.10), the finite-temperature part of the quark condensate takes the form

$$\langle \bar{q}q \rangle_T \langle 0 | \bar{q}q | 0 \rangle_0 \left( 1 - \frac{M^2}{32\pi^2 F^2} (2\bar{I}_3 - 1) \right)^{-1} = -\left\{ \frac{q_1}{F^2} T^2 + \frac{q_2}{F^4} T^4 + O(T^6) \right\}. \quad (3.8)$$

The respective coefficients,

$$q_1 = h_1(M^\pm_\pi, T, 0) + \frac{1}{8} a_0 h_1(M_\pi^0, T, 0) + \tilde{h}_1(M^\pm_\pi, T, H),$$

$$q_2 = \frac{1}{2} h_1(M^\pm_\pi, T, 0) h_1(M_\pi^0, T, 0) + \frac{1}{2} h_1(M_\pi^0, T, 0) \tilde{h}_1(M^\pm_\pi, T, H)$$

$$-\frac{1}{8} h_1(M_\pi^0, T, 0) h_1(M_\pi^0, T, 0) - \frac{1}{2} h_1(M_\pi^0, T, 0) h_2(M^\pm_\pi, T, 0)$$

$$-\frac{1}{8} a_0 \frac{m^2}{t^2} h_1(M^\pm_\pi, T, 0) h_2(M_\pi^0, T, 0) - \frac{1}{2} a_0 \frac{m^2}{t^2} \tilde{h}_1(M^\pm_\pi, T, H) h_2(M_\pi^0, T, 0)$$

$$+ \frac{1}{8} a_0 \frac{m^2}{t^2} h_1(M^\pm_\pi, T, 0) h_2(M_\pi^0, T, 0) - \frac{1}{2} a_0 \frac{m^2}{t^2} h_1(M^\pm_\pi, T, H) h_2(M_\pi^0, T, H), \quad (3.9)$$

depend in a nontrivial way on the ratios between pion masses, magnetic field and temperature. The NLO mass correction $a_0$ is

$$a_0 = \frac{d(M_\pi^0)^2}{dM_\pi^2} = 1 + \frac{K_1}{F^2} + \frac{M_\pi^2}{F^2} \frac{dK_1}{dM_\pi^2}, \quad (3.10)$$

with the integral $dK_1/dM_\pi^2$ given by

$$\frac{dK_1}{dM_\pi^2} = -\frac{1}{16\pi^2} \int_0^\infty d\rho \exp \left( -\frac{M_\pi^2}{|qH|\rho} \right) \left( \frac{1}{\sinh(\rho)} - \frac{1}{\rho} \right). \quad (3.11)$$

The coefficient $q_1$ refers to the free pion gas contribution of order $T^2$, while the coefficient $q_2$ captures the pion-pion interaction that emerges at order $T^4$ in the finite-temperature quark condensate.

To assess the magnitude of the interaction, in Fig. 2 we plot the dimensionless ratio

$$\xi_q(t, m, m_H) = \frac{q_2 T^2}{q_1 F^2} \quad (3.12)$$

8
that measures the effect of the pion-pion interaction in the quark condensate relative to the free pion gas contribution. The dimensionless quantities $t, m$, and $m_H,$

$$t = \frac{T}{4\pi F}, \quad m = \frac{M_\pi}{4\pi F}, \quad m_H = \sqrt{|qH|} \frac{4\pi F}{4\pi F},$$ (3.13)

that we use in the figures, capture temperature, pion mass, and strength of the magnetic field relative to the chiral symmetry breaking scale $\Lambda_\chi \approx 4\pi F \approx 1 GeV$. The quantities $t, m$, and $m_H$ must be small since chiral perturbation theory is a low-energy effective theory. Inspecting Fig. 2 – where we have chosen $T = 108$ $MeV$ and $T = 215$ $MeV$ as well as $m, m_H \leq 0.4$ – one notices that the interaction is largest in the chiral limit ($m \to 0$) when no magnetic field is present or when the magnetic field becomes stronger. The effect of the interaction is not tiny – rather it may constitute up to about ten percent relative to the leading free pion gas contribution.

In Fig. 3 we depict the sum of one- and two-loop contribution, i.e., the dimensionless quantity

$$-\left(q_1 + q_2 \frac{T^2}{F^2}\right),$$ (3.14)

for the same two temperatures $T = \{108$ $MeV, 215$ $MeV\}$, or, $t = \{0.1, 0.2\}$. As the plots indicate – at fixed $M_\pi$ and temperature – the finite-temperature quark condensate increases when the magnetic field grows. The effect is most pronounced in the chiral limit ($m \to 0$).

Let us examine the real world, where the pion masses are fixed at their physical values $M_\pi = 140$ $MeV$ ($m = 0.130\frac{5}{5}$). In Fig. 4 on the LHS, we plot the ratio $\xi_q$.

---

5For the tree-level pion decay constant we use the value $F = 85.6$ $MeV$ reported in Ref. 42. Note
as a function of temperature and magnetic field strength. The effect of the pion-pion interaction is less than ten percent in the parameter range $t, m_H \leq 0.25$ ($T \leq 269 \text{MeV}$, $|qH| \leq 269 \text{MeV}$) we are considering. Finally, on the RHS of Fig. 4 we depict the sum of one- and two-loop contribution in the quark condensate for the same parameter domain. One observes that the finite-temperature quark condensate slightly increases when the strength of the magnetic field grows while temperature is held constant. This effect however is small.

In the chiral limit, the finite-temperature quark condensate reduces to

$$
\frac{\langle \bar{q}q \rangle^T}{\langle 0|\bar{q}q|0 \rangle_0} = -\frac{T^2}{F^2} \left\{ \frac{1}{24} + h_1(M_H, T, 0) - \left( \frac{|qH| \ln 2}{32\pi^2 F^2} \right) h_1(0, T, 0) + \tilde{h}_1(M_H, T, H) \right\} \\
+ \frac{T^4}{24F^4} \left\{ \frac{1}{48} - h_1(M_H, T, 0) - \tilde{h}_1(M_H, T, H) \right\} + O(T^6). \quad (3.15)
$$

The mass $M_H$ depends on the magnetic field,

$$
M_H^2 = \frac{\tilde{t}_6 - \tilde{t}_5}{48\pi^2} \frac{|qH|^2}{F^2}, \quad (3.16)
$$

and corresponds to the charged pion mass in the chiral limit. The mass of the neutral pion, on the other hand, tends to zero in the chiral limit.\[6]

that in the isospin limit – and in zero magnetic field – the masses of the neutral and the charged pions are identical.

\[6]See Eqs. (2.13) and (2.14).
Figure 4: [Color online] LHS: Magnitude and sign of the pion-pion interaction in the finite-temperature QCD quark condensate measured by $\xi_q(t, m, m_H)$ at the physical value $M_\pi = 140$ MeV. RHS: Sum of one- and two-loop contribution of the finite-temperature quark condensate at the physical value $M_\pi$.

We now address the question of how the quark condensate in the chiral limit behaves in weak magnetic fields. In this limit – implemented by $|qH| \ll T^2$ – we have to expand the kinematical functions $h_1(M_H, T, 0)$ and $\tilde{h}_1(M_H, T, H)$ in Eq. (3.15) in the magnetic-field dependent mass $M_H$, which leads to

$$h_1(M_H, T, 0) = h_1(0, T, 0) - \alpha \epsilon^2 h_2(0, T, 0) + \frac{\alpha^2 \epsilon^4}{2!} h_3(0, T, 0) + \mathcal{O}(h_4),$$

$$\tilde{h}_1(M_H, T, H) = \tilde{h}_1(0, T, H) - \alpha \epsilon^2 \tilde{h}_2(0, T, H) + \frac{\alpha^2 \epsilon^4}{2!} \tilde{h}_3(0, T, H) + \mathcal{O}(\tilde{h}_4),$$

with

$$\alpha = \frac{7_6 - 7_5}{3} t^2, \quad t = \frac{T}{4\pi F}.$$ (3.18)

The structure of this infinite series of kinematical functions is analyzed in Appendix C. While the functions $h_1(0, T, 0)$ and $\tilde{h}_1(0, T, H)$ are well-defined, it should be pointed out that for $r = 2, 3, 4, \ldots$, the functions $h_r(0, T, 0)$ and $\tilde{h}_r(0, T, H)$ generate various types of divergences in the weak magnetic field expansion parameter $\epsilon$. The notation $h_2(0, T, 0), \tilde{h}_2(0, T, H), h_3(0, T, 0), \tilde{h}_3(0, T, H), \ldots$ is therefore symbolic: it is understood that these functions contain inverse powers of $\epsilon$ as well as logarithms $\ln \epsilon$. These pieces – according to Eq. (3.17) – are then multiplied by even powers of $\epsilon$, in such a way that all divergences ultimately disappear in the quark condensate, as we show in Appendix C. The outcome is the following series for the finite-temperature
two-loop quark condensate in the chiral limit and in weak magnetic fields:

\[
\frac{\langle \bar{q}q \rangle_T}{\langle 0 | \bar{q}q | 0 \rangle_0} = -\frac{1}{8F^2} T^2 + \frac{1}{F^2} \left\{ \frac{|I_\frac{1}{2}|}{8\pi^{3/2}} \sqrt{\epsilon} - \frac{\ln 2}{16\pi^2} \epsilon 
- \frac{\sqrt{2} - 4}{8} \gamma \zeta\left(\frac{3}{2}\right) \epsilon^{3/2} + \frac{\gamma}{4\pi} \epsilon^2 \ln \epsilon + \mathcal{O}(\epsilon^2) \right\} T^2
- \frac{1}{384F^4} T^4 + \frac{1}{F^4} \left\{ \frac{|I_\frac{1}{2}|}{192\pi^{3/2}} \sqrt{\epsilon} 
- \frac{\sqrt{2} - 4}{192} \gamma \zeta\left(\frac{3}{2}\right) \epsilon^{3/2} + \frac{\gamma}{96\pi} \epsilon^2 \ln \epsilon + \mathcal{O}(\epsilon^2) \right\} T^4 + \mathcal{O}(T^6). \tag{3.19}
\]

Recall that \(\epsilon,\)

\[
\epsilon = \frac{|qH|}{T^2}, \tag{3.20}
\]
is the relevant expansion parameter, while the other quantities are

\[
I_{\frac{1}{2}} = \int_0^\infty \! d\rho \rho^{-1/2} \left( \frac{1}{\sinh(\rho)} - \frac{1}{\rho} \right) \approx -1.516256,
\]

\[
\gamma = \frac{I_6 - I_5}{12\pi} t^2, \quad t = \frac{T}{4\pi F}. \tag{3.21}
\]

The first two lines of Eq. (3.19) refer to one-loop order \((\propto T^2),\) while the remaining two lines represent two-loop corrections \((\propto T^4).\) In the chiral limit, the series for the finite-temperature quark condensate in weak magnetic fields is thus characterized by square-root terms \(\propto \sqrt{\epsilon},\) a term linear in \(\epsilon,\) followed by half-integer powers \(\epsilon^{3/2}\) and logarithmic contributions of the form \(\epsilon^2 \ln \epsilon.\) The remaining contributions involve even powers of \(\epsilon.\) Notice that the leading corrections – proportional to \(\sqrt{\epsilon}\) – come with a positive sign: in the chiral limit, as already illustrated by Fig. 3, the finite-temperature quark condensate grows if the magnetic field is switched on.

The published results in Refs. [3–5, 8–10] do not quite agree with the above representation. The correct series at one-loop order has been derived and discussed in Ref. [36]. The two-loop contribution in nonzero magnetic fields, displayed in the second brace of Eq. (3.19), again differs from the published two-loop result, Eq.(5.8) of Ref. [10]: the term

\[
\frac{5\sqrt{|qH|T^3}}{1536\pi F^4} \tag{3.22}
\]
in Eq.(5.8) of Ref. [10] should rather read

\[
\frac{\sqrt{|qH|T^3}}{192\pi^{3/2} F^4} |I_{\frac{1}{2}}|. \tag{3.23}
\]

The numerical discrepancy is

\[
\frac{5}{1536\pi} \approx 0.00103616, \quad \frac{|I_{\frac{1}{2}}|}{192\pi^{3/2}} \approx 0.00141823. \tag{3.24}
\]
Moreover, a term linear in $\epsilon$ in the second brace of Eq. (3.19) does not emerge in our expansion – contradicting the result announced in Ref. [10]. It should be emphasized that the series provided in the literature is restricted to linear order in $\epsilon$, while we have analyzed the full structure of the weak magnetic field expansion of the finite-temperature quark condensate in the chiral limit up to two loops.

### 3.2 Zero-Temperature Quark Condensate

We now turn to the quark condensate at zero temperature:

$$\langle 0 | \bar{q} q | 0 \rangle = \frac{\langle 0 | \bar{q} q | 0 \rangle_0}{F^2} \frac{dz_0}{dM^2}. \quad (3.25)$$

Recall that $\langle 0 | \bar{q} q | 0 \rangle_0$ is the quark condensate at $T=0$, $H=0$ and $M=0$. On the basis of the representations Eqs. (2.18) and (2.20) for the vacuum energy density, we derive

$$\frac{\langle 0 | \bar{q} q | 0 \rangle}{\langle 0 | \bar{q} q | 0 \rangle_0} = 1 - \frac{7_3 - 47_1}{32\pi^2} \frac{M^2}{F^2} - \frac{K_1}{F^2} + \frac{37_3}{1024\pi^4} \frac{M^4}{F^4} - \frac{97_3(3\tau_{10} + 2\tau_{11})}{1024\pi^4} \frac{M^4}{F^4} - \frac{7_5}{768\pi^4} \frac{|qH|^2}{F^4} + \frac{(7_6 - 7_5)\tau_{34}}{768\pi^4} \frac{|qH|^2}{F^4} - \frac{1}{32\pi^2} \frac{M^2}{F^4} K_1$$

$$+ \frac{7_3}{16\pi^2} \frac{M^2}{F^4} K_1 + \frac{7_3}{32\pi^2} \frac{M^4}{F^4} \frac{dK_1}{dM^2} - \frac{(7_6 - 7_5)}{48\pi^2} \frac{|qH|^2}{F^4} \frac{dK_1}{dM^2}. \quad (3.26)$$

The explicit expressions for $K_1$ and $dK_1/dM^2$,

$$K_1 = \frac{M^2}{16\pi^2} - \frac{M^2}{16\pi^2} \ln \frac{M^2}{2|qH|} + \frac{|qH|}{8\pi^2} \ln \Gamma \left( \frac{M^2}{2|qH|} + \frac{1}{2} \right) - \frac{|qH|}{16\pi^2} \ln 2\pi,$$

$$\frac{dK_1}{dM^2} = \frac{1}{16\pi^2} \ln \frac{|qH|}{M^2} + \frac{1}{16\pi^2} \Psi \left( \frac{M^2}{2|qH|} + \frac{1}{2} \right) + \frac{\ln 2}{16\pi^2}, \quad (3.27)$$

are derived in Appendix B. The series for the quark condensate is organized according to ascending powers of $M^2$ and $|qH|$ – both quantities count as order $p^2$. The respective coefficients depend in a nontrivial manner on the ratio $M^2/|qH|$ and involve renormalized NLO and NNLO effective constants. Let us compare our result with the literature.

The focus of the two-loop CHPT calculation presented in Ref. [7], was to determine the shift in the zero-temperature quark condensate caused by an external (electro)magnetic field. Our expression, Eq. (3.26), goes beyond the literature since we have derived the whole two-loop representation for the quark condensate – not just the terms induced by the magnetic field.

To analyze the chiral limit of the zero-temperature quark condensate in finite magnetic fields, we invoke the behavior of the NLO and NNLO effective constants.
According to Appendix A we have
\[ l_3, l_5, l_6 \propto \ln M^2, \]
\[ \tau_{34} \propto \ln M^2, \]
\[ \tau_{10} + 2\tau_{11} \propto \ln M^2, \] (3.28)
i.e., the renormalized NLO and NNLO effective constants explode in the limit \( M \to 0 \). But note that in the quark condensate these constants are multiplied by powers of \( M^2 \) such that the chiral limit is in fact unproblematic. While some terms in Eq. (3.26) hence disappear in the chiral limit, only the following two terms,
\[ \frac{(l_6 - l_5)}{768\pi^4} c_{34} |qH|^2 - \frac{(l_6 - l_5)}{768\pi^4} \frac{|qH|^2}{F^4} \ln \left( \frac{|qH|}{M^2} \right), \] (3.29)
need special consideration, as they both explode in the chiral limit. However, writing the NNLO effective constant \( \tau_{34} \) as
\[ \tau_{34} = \ln \left( \frac{\Lambda_{34}^2}{M_5^2} \right), \] (3.30)
where \( \Lambda_{34} \) is the renormalization group invariant scale associated with \( \tau_{34} \), the two terms can be merged such that the zero-temperature quark condensate in nonzero magnetic fields is well-defined in the chiral limit, taking the form
\[ \frac{\langle 0|\bar{q}q|0 \rangle}{\langle 0|\bar{q}q|0 \rangle_0} = 1 + \frac{\ln 2}{16\pi^2} \frac{|qH|^2}{F^2} - \frac{(l_6 - l_5)}{768\pi^4} \frac{|qH|^2}{F^4} \ln \left( \frac{|qH|}{\Lambda_{34}^2} \right) - \frac{(l_6 - l_5)}{768\pi^4} \frac{|qH|^2}{F^4} \left( \frac{\Gamma'\left(\frac{1}{2}\right)}{\Gamma\left(\frac{1}{2}\right)} + \ln 2 \right). \] (3.31)
Notice that the \( \ln M^2 \)-dependence in the combination \( l_6 - l_5 \) cancels, and we can write
\[ l_6 - l_5 = \ln \left( \frac{\Lambda_6^2}{\Lambda_5^2} \right), \] (3.32)
where \( \Lambda_5 \) and \( \Lambda_6 \) are the respective renormalization group invariant scales associated with the NLO effective constants \( l_5 \) and \( l_6 \).

4 Conclusions

We have explored the behavior of the quark condensate subjected to an external magnetic field within the framework of chiral perturbation theory. Unlike previous two-loop evaluations by other authors, we have used a coordinate space representation.

Regarding the finite-temperature quark condensate in the chiral limit and in weak magnetic fields, we have pointed out various errors that have occurred in the literature.
and have provided the correct series. At order $T^2$ – and in terms of the expansion parameter $\epsilon = |qH|/T^2$ – the leading contribution is proportional to $\sqrt{\epsilon}$, followed by a term linear in $\epsilon$, a half-integer power $\epsilon^{3/2}$ and a logarithmic contribution $\epsilon^2 \ln \epsilon$. The remaining contributions involve even powers of $\epsilon$. At order $T^4$ the pattern repeats itself with the exception that a term linear in $\epsilon$ does not occur.

Leaving the weak magnetic field limit, we have investigated the impact of the magnetic field on the quark condensate at finite temperature. Emphasis was put on the effect of the pion-pion interaction which constitutes up to about ten percent for arbitrary pion masses but also in the real world where $M_\pi = 140 \text{ MeV}$. The interaction is largest in the chiral limit. The finite-temperature quark condensate (sum of one- and two-loop contribution) at fixed temperature and fixed pion mass grows monotonically when the magnetic field strength increases. Again, the effect is most pronounced in the chiral limit.

Finally we have derived the two-loop representation for the QCD vacuum energy density and the quark condensate at zero temperature. We have complemented earlier studies by other authors, by providing the full two-loop representation, i.e., not just the terms that emerge on account of the nonzero magnetic field.

A natural – but highly nontrivial – step is to extend the present analysis to the three-loop level, in analogy to the three-loop analysis in zero magnetic field given in the pioneering article [43], based on a coordinate space representation of CHPT. Corresponding work is in progress.

A Order-$p^6$ Free Energy Density at $T=0$

A.1 Low-Energy Effective Constants at NLO and NNLO

The aim of the present appendix is to discuss the renormalization group running of the NLO and NNLO effective constants $l_i^r$ and $c_i^r$ in some detail, and then to provide a definition of the renormalized NNLO effective constants $\tilde{c}_i$ – in analogy to the definition of the renormalized NLO quantities $\tilde{l}_i$. 

15
The NNLO effective constants $c_i$ that appear in $\mathcal{L}_{\text{eff}}^6$, are defined in Ref. [39] as
\[
c_i = \frac{(c\mu)^2(d-4)}{F^2} \left\{ c_i^r - \gamma_i^{(2)} \Lambda^2 - \gamma_i^{(1)} \Lambda - \gamma_i^{(L)} \Lambda \right\}, \tag{A.1}
\]
with
\[
\Lambda = \frac{1}{16\pi^2} \frac{1}{d-4}, \quad \ln c = -\frac{1}{2} \ln 4\pi + \Gamma'(1) + 1. \tag{A.2}
\]
The quantities $\gamma_i^{(1)}$, $\gamma_i^{(2)}$ are pure numbers and the $c_i^r$ are the renormalized running NNLO effective constants. For the definition of the NLO effective constants $l_i$ that appear in $\mathcal{L}_{\text{eff}}^4$, on the other hand, we adopt the definition given in the original Ref. [41],
\[
l_i = l'_i + \gamma_i \lambda, \tag{A.3}
\]
where
\[
\lambda = \frac{1}{2} (4\pi)^{-\frac{d}{2}} \Gamma(1 - \frac{1}{2}d) \mu^{d-4}
= \frac{\mu^{d-4}}{16\pi^2} \left[ \frac{1}{d-4} - \frac{1}{2} \ln 4\pi + \Gamma'(1) + 1 \right] + \mathcal{O}(d-4). \tag{A.4}
\]
The $\gamma_i$ are pure numbers and the $l'_i$ are the renormalized running NLO effective constants. The definition, Eq. (A.3), can be rewritten as
\[
l_i = l'_i + (c\mu)^{d-4} \gamma_i \Lambda. \tag{A.5}
\]
Note that the $\gamma_i$ also show up in $\gamma_i^{(L)}$, Eq. (A.1), in the form of
\[
\gamma_i^{(L)} = \sum_j \gamma_{ij}^{(L)} (c\mu)^{-(d-4)} l'_j, \tag{A.6}
\]
where the coefficients $\gamma_{ij}^{(L)}$ are again pure numbers.

Since the $c_i$ do not depend on the renormalization scale $\mu$, one concludes that the renormalization group running of the NNLO effective constants $c_i^r$ is
\[
\mu \frac{dc_i^r}{d\mu} = -2(d-4)c_i^r + \frac{\gamma_i^{(1)}}{8\pi^2} + \frac{\gamma_i^{(L)}}{16\pi^2}. \tag{A.7}
\]
In the above derivation we have used the fact that the NLO effective constants $l'_i$ themselves obey the running
\[
\mu \frac{dl'_i}{d\mu} = -\frac{\gamma_i^{(2)}}{16\pi^2} (c\mu)^{d-4}, \tag{A.8}
\]
which follows from the fact that the $l_i$ do not depend on $\mu$. Furthermore, with the Weinberg consistency condition [44],
\[
-2\gamma_i^{(2)} + \sum_j \gamma_{ij}^{(L)} \gamma_j = 0, \tag{A.9}
\]
a divergence linear in $\Lambda$ has been eliminated in Eq. (A.7).

Instead of the NLO quantities $l_i^r$ that depend on the renormalization scale, alternatively one often uses the NLO effective constants $\bar{l}_i$ that are $\mu$-independent. The connection between the two is [41]

$$l_i^r = \frac{\gamma_i}{32\pi^2} \left( \bar{l}_i + \ln \frac{M^2}{\mu^2} \right). \quad \text{(A.10)}$$

Let us transfer this connection to NNLO. The specific NNLO effective constants that appear in the vacuum energy density are $c_{10}, c_{11}$ and $c_{34}$, where the last one only matters when a magnetic field is present. Following Ref. [39] – but using the convention (A.3) – it reads

$$c_{34} = \left( \frac{c\mu}{F^2} \right)^2 \bar{c}_{34}^r + \frac{l_5^r - \frac{1}{2} l_6^r}{F^2} \lambda. \quad \text{(A.11)}$$

Explicitly, the running of $c_{34}^r$ is given by

$$\frac{dc_{34}^r}{d\mu^2} = -\frac{l_5^r - \frac{1}{2} l_6^r}{32\pi^2 \mu^2}. \quad \text{(A.12)}$$

In analogy to the above definition for the NLO constants $\bar{l}_i$, Eq. (A.10), that is based on the running (A.8), we define the renormalized NNLO effective constant $\bar{c}_{34}$ as

$$\bar{c}_{34} = \frac{7_6 - 7_5}{6144\pi^4} \bar{c}_{34} + \frac{7_6 - 7_5}{6144\pi^4} \ln \frac{M^2}{\mu^2}. \quad \text{(A.13)}$$

Note that we have used

$$\gamma_5 = -\frac{1}{6}, \quad \gamma_6 = -\frac{1}{3}. \quad \text{(A.14)}$$

Since $c_{34}^r$ does not depend on $M$, we conclude

$$\frac{dc_{34}}{dM^2} = -\frac{1}{M^2}. \quad \text{(A.15)}$$

The NNLO constant $\bar{c}_{34}$ hence obeys the same simple relation as the NLO constants $\bar{l}_i$,

$$\frac{d\bar{l}_i}{dM^2} = -\frac{1}{M^2}. \quad \text{(A.16)}$$

Next we consider the NNLO effective constants $c_{10}$ and $c_{11}$ that arise in the tree-level contribution $z_{6C}$ in the absence of the magnetic field. They are defined as (see Ref. [39])

$$c_{10} = \left( \frac{c\mu}{F^2} \right)^{2(d-4)} c_{10}^r + \frac{3}{64F^2} \lambda^2 - \frac{1}{F^2} \left( \frac{3}{16} l_3^r + \frac{1}{16} l_7^r \right) \lambda,$$

$$c_{11} = \left( \frac{c\mu}{F^2} \right)^{2(d-4)} c_{11}^r - \frac{9}{128F^2} \lambda^2 + \frac{1}{F^2} \left( \frac{9}{32} l_3^r + \frac{1}{32} l_7^r \right) \lambda. \quad \text{(A.17)}$$
Note that in the linear combination $c_{10} + 2c_{11} - as it appears in the vacuum energy density at order $p^6$ - the dependence on $l_3$ cancels and we are left with

$$c_{10} + 2c_{11} = \frac{(c\mu)^2}{F^2} (c_{10}^r + 2c_{11}^r) - \frac{3}{32F^2} \lambda^2 + \frac{3}{8F^2} l_3^r \lambda.$$

(A.18)

Since the $c_i$ do not depend on the renormalization scale $\mu$, we conclude

$$\frac{d(c_{10}^r + 2c_{11}^r)}{d\mu^2} = -\frac{3l_3^r}{256\pi^2} \frac{1}{\mu^2}.$$

(A.19)

Equivalently, by making the replacement $l_3^r \to \bar{l}_3$,

$$l_3^r = \frac{\gamma_3}{32\pi^2} (\bar{l}_3 + \ln \frac{M^2}{\mu^2}), \quad \gamma_3 = \frac{1}{2},$$

(A.20)

we can write

$$\frac{d(c_{10}^r + 2c_{11}^r)}{d\mu^2} = \frac{3\bar{l}_3}{16384\pi^4} \frac{1}{\mu^2} - \frac{3}{16384\pi^4} \frac{1}{\mu^2} \ln \frac{M^2}{\mu^2}.$$  \hspace{1cm} (A.21)

This leads us to the definition of the renormalized combination $\tau_{10} + 2\tau_{11}$ as

$$c_{10}^r + 2c_{11}^r = -\frac{3\bar{l}_3}{16384\pi^4} (\tau_{10} + 2\tau_{11}) - \frac{3\bar{l}_3}{16384\pi^4} \ln \frac{M^2}{\mu^2} - \frac{3}{32768\pi^4} \left( \ln \frac{M^2}{\mu^2} \right)^2. \hspace{1cm} (A.22)$$

By construction, the linear combination $\tau_{10} + 2\tau_{11}$ is independent of $\mu$, much like $\tau_{34}$ and the $l_i$. Because the expression $c_{10}^r + 2c_{11}^r$ does not depend on $M$, we also conclude

$$\frac{d(\tau_{10} + 2\tau_{11})}{dM^2} = -\frac{1}{M^2} + \frac{1}{M^2} \frac{\tau_{10} + 2\tau_{11}}{\bar{l}_3}. \hspace{1cm} (A.23)$$

### A.2 Isolating UV-divergences

Here we focus on the zero-temperature contributions in the free energy density that emerge at order $p^6$ due to the three diagrams 6A-C displayed Fig. 1. The unrenormalized expressions that contain both $T=0$ and finite-temperature pieces are

$$z_{6A} = \frac{M^2}{2F^2} G_1^+ G_1^0 - \frac{M^2}{8F^2} G_1^0 G_1^0,$$

$$z_{6B} = (4l_5 - 2l_6) \frac{|qH|^2}{F^2} G_1^+ + 2l_3 \frac{M^4}{F^2} G_1^+ + l_3 \frac{M^4}{F^2} G_1^0,$$

$$z_{6C} = -16(c_{10} + 2c_{11}) M^6 - 8c_{34} |qH|^2 M^2,$$

(A.24)

where $G_1^+$ and $G_1^0$ are the thermal pion propagators evaluated at the coordinate origin $x=0$,

$$G_1^+ = G^+(0), \quad G_1^0 = G^0(0).$$

(A.25)
Inserting the decomposition of thermal propagators into zero-temperature and finite-temperature pieces (defined in Eq. (2.11))

\[ G_\pm^1 = \Delta_\pm^0(0) + \tilde{g}_1(M, T, H) + g_1(M, T, 0), \]
\[ G_0^1 = \Delta_0^0(0) + g_1(M, T, 0), \]

(A.26)

and using the representations of the zero-temperature propagators \( \Delta_\pm^0(0) \) and \( \Delta_0^0(0) \),

\[ \Delta_\pm^0(0) = 2M^2\lambda + K_1, \]
\[ \Delta_0^0(0) = 2M^2\lambda, \]

(A.27)

we obtain

\[ K_1 = \frac{|qH|^d}{(4\pi)^d} \int_0^\infty d\rho \rho^{-d+1} \exp \left( -\frac{M^2}{|qH|^2}\rho \right) \left( \frac{1}{\sinh(\rho)} - \frac{1}{\rho} \right), \]
\[ \lambda = \frac{1}{2} (4\pi)^{-d} \Gamma(1 - \frac{1}{2}d)M^{d-4} \]
\[ = \frac{M^{d-4}}{16\pi^2} \left[ \frac{1}{d-4} - \frac{1}{2}(\ln 4\pi + \Gamma'(1) + 1) + \mathcal{O}(d-4) \right], \]

(A.28)

The upper index "0" signals that we are considering the \( T=0 \) part only.\footnote{To isolate the UV-divergences in this unrenormalized expression, we use the conventions for the NLO and NNLO effective constants \( l_i \) and \( c_i \), respectively, that we have provided in Appendix A.1. One finds that in the sum of the three diagrams, all UV-divergences disappear and the renormalized order-\( \rho^6 \) vacuum energy density takes the form

\[ z_0^6 = \frac{3M^6}{2F^2} \lambda^2 + \frac{M^4}{F^2} K_1 \lambda, \]
\[ z_{6A}^0 = 6l_3 \frac{M^6}{F^2} \lambda + 2l_3 \frac{M^4}{F^2} K_1 + (8l_5 - 4l_6) \frac{M^2|qH|^2}{F^2} \lambda + (4l_5 - 2l_6) \frac{|qH|^2}{F^2} K_1, \]
\[ z_{6C}^0 = -16(c_{10} + 2c_{11})M^6 - 8c_{34}|qH|^2M^2. \]

(A.29)

The above representation is renormalization-scale independent. This constitutes a nontrivial check of our calculation.

\footnote{The finite-temperature contribution \( z^T \) is given by Eq. (2.10).}
B Analysis of the Integral $K_1$

To analyze the free energy density and the quark condensate in the chiral limit, we must have a closer look at the dimensionally regularized integral $K_1$,

$$
K_1 = \frac{|qH|^\frac{d-1}{2}}{(4\pi)^\frac{d}{2}} \int_0^\infty d\rho \rho^{-\frac{d}{2}+1} \exp \left( -\frac{M^2}{|qH|\rho} \left( \frac{1}{\sinh(\rho)} - \frac{1}{\rho} \right) \right). \tag{B.1}
$$

To this end we first consider the integral $I_2$, defined in (A1) of Ref. [36] as

$$
I_2 = \frac{|qH|^\frac{d}{2}}{(4\pi)^\frac{d}{2}} \int_0^\infty d\rho \rho^{-\frac{d}{2}} \left( \frac{1}{\sinh(\rho)} - \frac{1}{\rho} \right) \exp \left( -\frac{M^2}{|qH|\rho} \right),
$$

$$
= -\frac{|qH|^3}{96\pi^2M^2} \int_0^\infty d\rho \rho^{-\frac{d}{2}} \left( \frac{1}{\sinh(\rho)} - \frac{1}{\rho} + \frac{\rho}{6} \right) \exp \left( -\frac{M^2}{|qH|\rho} \right). \tag{B.2}
$$

Comparing these representations, one concludes

$$
\frac{dK_1}{dM^2} = \frac{dI_2}{dM^2},
$$

$$
\frac{d^2K_1}{dM^2} = \frac{d^2I_2}{(dM^2)^2}. \tag{B.3}
$$

Using the property of the Riemann zeta function

$$
\lim_{s \to 1} \zeta(s, q) = \frac{1}{s-1} - \frac{\Gamma'(q)}{\Gamma(q)}, \tag{B.4}
$$

where

$$
\zeta(s, q) = \sum_{n=0}^\infty \frac{1}{(q+n)^s}, \tag{B.5}
$$

the second relation in Eq. (B.3) yields

$$
\frac{dK_1}{dM^2} = \frac{1}{16\pi^2} \ln \frac{|qH|}{M^2} + \frac{1}{16\pi^2} \Psi \left( \frac{M^2}{2|qH|} + \frac{1}{2} \right) + \ln 2 \frac{1}{16\pi^2}, \tag{B.6}
$$

where $\Psi(x)$ is the Polygamma function

$$
\Psi(x) = \frac{\Gamma'(x)}{\Gamma(x)}. \tag{B.7}
$$

The expression for $K_1$ is obtained by integration,

$$
K_1 = \frac{M^2}{16\pi^2} - \frac{M^2}{16\pi^2} \ln \frac{M^2}{2|qH|} + \frac{|qH|}{8\pi^2} \ln \Gamma \left( \frac{M^2}{2|qH|} + \frac{1}{2} \right) + C(|qH|). \tag{B.8}
$$

---

Footnote 8: The physical limit $d \to 4$ is straightforward and does not pose any problems.
The integration constant \( C(|qH|) \) can be determined by setting \( M=0 \) in the equation above and in the original representation, Eq. (B.1). One identifies

\[
C(|qH|) = -\frac{|qH|}{16\pi^2} \ln 2\pi .
\] (B.9)

While \( K_1 \) appears in the free energy density, the derivative \( dK_1/dM^2 \) is relevant in the quark condensate.

## C Bose Functions in the Chiral Limit

The finite-temperature representation of the quark condensate in the chiral limit, Eq. (3.15), features an infinite series of kinematical Bose functions \( g_r \) and \( \tilde{g}_r \) that has to be resummed because of the weak magnetic field expansion Eq. (3.17). This is the main focus of the present appendix. The aim is to provide explicit expressions up to order \( \epsilon^2 \ln \epsilon \) in the finite-temperature quark condensate.

We first consider the second type of functions\(^9\)

\[
\tilde{g}_r(M_H^\pm, T, H) = \frac{\epsilon}{(4\pi)^{r+1}} T^{d-2r} \int_0^\infty d\rho \rho^{-d/4+r} \exp \left( -\frac{(M_H^\pm)^2}{4\pi T^2} \rho \right) \times \left( \frac{1}{\sinh(\epsilon \rho / 4\pi)} - \frac{2\pi}{\epsilon \rho} \right) \left[ S \left( \frac{1}{\rho} \right) - 1 \right].
\] (C.1)

The crucial point is that – in the chiral limit – the mass \( M_H^\pm \) of the charged pions does not tend to zero. Rather, according to Eq. (2.13), a magnetic-field dependent mass term survives the chiral limit,

\[
M_H^2 = \frac{7_6 - 7_5 |qH|^2}{48\pi^2} = \frac{16\pi^2}{3} \left( 7_6 - 7_5 \right) t^4 F^2 \epsilon^2 ,
\] (C.2)

with

\[
t = \frac{T}{4\pi F} .
\] (C.3)

The pertinent expansion parameter in the weak magnetic field limit \( |qH| \ll T^2 \) is

\[
\epsilon = \frac{|qH|}{T^2} .
\] (C.4)

To isolate divergences in the kinematical functions \( \tilde{g}_r \) (where \( r = 0, 1, 2, \ldots \)) that arise in the limit \( \epsilon \to 0 \) \((T \text{ held fixed while } H \to 0)\), we decompose \( \tilde{g}_r(M_H, T, H) \) into two

---

\(^9\)It should be noted that the functions \( \tilde{g}_r, g_r \) – up to temperature powers – coincide with the functions \( h_r, h_r \). The conversion is given by Eq. (3.7).
pieces,
\[
\tilde{g}_t(M_H, T, H) = \frac{\epsilon T^{d-2r}}{(4\pi)^{r+1}} \int_0^1 d\rho \rho^{-\frac{d}{2} + \frac{3}{2} + \frac{1}{\epsilon} e^{t/\epsilon^2}} \left( \frac{1}{\sinh(\epsilon \rho / 4\pi)} - \frac{4\pi}{\epsilon \rho} \right) \left[ S\left( \frac{1}{\rho} \right) - 1 \right] \\
+ \frac{\epsilon T^{d-2r}}{(4\pi)^{r+1}} \int_1^\infty d\rho \rho^{-\frac{d}{2} + \frac{3}{2} + \frac{1}{\epsilon} e^{t/\epsilon^2}} \left( \frac{1}{\sinh(\epsilon \rho / 4\pi)} - \frac{4\pi}{\epsilon \rho} \right) \left[ S\left( \frac{1}{\rho} \right) - 1 \right] \\
- \frac{\epsilon T^{d-2r}}{(4\pi)^{r+1}} \int_1^\infty d\rho \rho^{-\frac{d}{2} + \frac{3}{2} + \frac{1}{\epsilon} e^{t/\epsilon^2}} \left( \frac{1}{\sinh(\epsilon \rho / 4\pi)} - \frac{4\pi}{\epsilon \rho} \right) \left[ S\left( \frac{1}{\rho} \right) - 1 \right]
\]
\[= I_a + I_b, \tag{C.5}\]
where
\[\gamma = \frac{\tilde{t}_6 - \tilde{t}_5}{12\pi} \epsilon^2. \tag{C.6}\]
The first integral \(I_a\) exists for integer \(r = 0, 1, 2, \ldots\). Taylor expanding the integrand in the parameter \(\epsilon\), we obtain a series with ascending even powers of \(\epsilon\) for \(r = 0, 1, 2, \ldots\),
\[\alpha_1 \epsilon^2 + \alpha_2 \epsilon^4 + \alpha_3 \epsilon^6 + O(\epsilon^8). \tag{C.7}\]
The explicit coefficients are irrelevant for our purposes because the respective terms do not contribute to the quark condensate at the accuracy we are interested in (up to \(\epsilon^2 \ln \epsilon\) in the finite-temperature quark condensate). In particular, no \(\epsilon\)-divergences come from here.

We thus examine the second integral \(I_b\) in Eq. (C.5) that we process by using the Jacobi identity
\[S\left( \frac{1}{z} \right) = \sqrt{z} S(z). \tag{C.8}\]
We then obtain the three integrals
\[I_b = \frac{\epsilon T^{d-2r}}{(4\pi)^{r+1}} \int_0^1 d\rho \rho^{-\frac{d}{2} + \frac{3}{2} + \frac{1}{\epsilon} e^{t/\epsilon^2}} \left( \frac{1}{\sinh(\epsilon \rho / 4\pi)} - \frac{4\pi}{\epsilon \rho} \right) \left[ S\left( \frac{1}{\rho} \right) - 1 \right] \\
+ \frac{\epsilon T^{d-2r}}{(4\pi)^{r+1}} \int_1^\infty d\rho \rho^{-\frac{d}{2} + \frac{3}{2} + \frac{1}{\epsilon} e^{t/\epsilon^2}} \left( \frac{1}{\sinh(\epsilon \rho / 4\pi)} - \frac{4\pi}{\epsilon \rho} \right) \left[ S\left( \frac{1}{\rho} \right) - 1 \right] \\
- \frac{\epsilon T^{d-2r}}{(4\pi)^{r+1}} \int_1^\infty d\rho \rho^{-\frac{d}{2} + \frac{3}{2} + \frac{1}{\epsilon} e^{t/\epsilon^2}} \left( \frac{1}{\sinh(\epsilon \rho / 4\pi)} - \frac{4\pi}{\epsilon \rho} \right) \left[ S\left( \frac{1}{\rho} \right) - 1 \right]
\]
\[= I_{b1} + I_{b2} + I_{b3}. \tag{C.9}\]
The first one \(- I_{b1}\) exists for integer \(r = 0, 1, 2, \ldots\). Taylor expanding the integrand and then integrating term by term we get a series of the form
\[\beta_1 \epsilon^2 + \beta_2 \epsilon^4 + \beta_3 \epsilon^6 + O(\epsilon^8). \tag{C.10}\]
Again, the coefficients are irrelevant at the accuracy we are interested in. To isolate potential \(\epsilon\)-divergences in \(I_{b2}\), we write the integration limits as
\[I_{b2} = \frac{\epsilon T^{d-2r}}{(4\pi)^{r+1}} \int_0^1 d\rho \rho^{-\frac{d}{2} + \frac{3}{2} + \frac{1}{\epsilon} e^{t/\epsilon^2}} \left( \frac{1}{\sinh(\epsilon \rho / 4\pi)} - \frac{4\pi}{\epsilon \rho} \right) \\
- \frac{\epsilon T^{d-2r}}{(4\pi)^{r+1}} \int_0^1 d\rho \rho^{-\frac{d}{2} + \frac{3}{2} + \frac{1}{\epsilon} e^{t/\epsilon^2}} \left( \frac{1}{\sinh(\epsilon \rho / 4\pi)} - \frac{4\pi}{\epsilon \rho} \right). \tag{C.11}\]
The first expression can be integrated analytically,
\[ I_{b2}^{[1]} = T^{d-2} \Gamma(r-\frac{3}{2}) \left[ -\frac{\gamma^{2-r}}{(4\pi)^{\frac{d}{2}}} e^{3-2r} + 2^{-r-\frac{5}{2}} \pi^{-\frac{3}{4}} (2r-3) \zeta(r-\frac{1}{2}, \frac{1}{2} + 2\pi \gamma \epsilon) \epsilon^{2-r} \right], \quad (C.12) \]
where the generalized Riemann zeta function is defined as
\[ \zeta(s, a) = \sum_{k=0}^{\infty} \frac{1}{(k + a)^s}. \quad (C.13) \]

One notices that the integral \( I_{b2}^{[1]} \) (for integer \( r \geq 2 \)) leads to \( \epsilon \)-divergences in the functions \( \tilde{g}_r \), namely
\[ \tilde{g}_r \propto \frac{1}{\epsilon^{2r-3}}, \frac{1}{\epsilon^{r-\frac{3}{2}}}. \quad (C.14) \]

As it turns out, these are indeed the leading divergences in the Bose functions \( \tilde{g}_r \). With the second expression \( -I_{b2}^{[2]} \) in Eq. (C.11) we proceed as before: Taylor expanding the integrand again gives rise to a series displaying even \( \epsilon \)-powers whose respective coefficients are of no concern to us.

Finally, we analyze the remaining third integral \( I_{b3} \) in Eq. (C.9). Regularizing it with \( N \gg 1 \),
\[ I_{b3} = \lim_{N \to \infty} -\frac{\epsilon T^{d-2} \Gamma(r-\frac{3}{2})}{(4\pi)^{\frac{d}{2}}} \int_1^N d\rho \rho^{-\frac{3}{2}} e^{-\gamma \epsilon^2 \rho} \left( \frac{1}{\sinh(\epsilon \rho / 4\pi)} - \frac{4\pi}{\epsilon \rho} \right), \quad (C.15) \]
the substitution \( z = \ln(\epsilon u) \) – for the specific case \( r=2 \) (and \( d=4 \)) – leads to
\[ I_{b3}(r = 2) = \lim_{N \to \infty} -\frac{\epsilon^{-4\pi \gamma \epsilon}}{16\pi^2} \int_{u_0}^{u_N} du \ u^{-1-4\pi \gamma \epsilon} \left( \frac{1}{\sinh(\ln \epsilon u)} - \frac{1}{\ln \epsilon u} \right), \quad (C.16) \]
with
\[ u_0 = \frac{e^{\frac{\pi}{2}}}{\epsilon}, \quad u_N = \frac{e^{\frac{N \pi}{2}}}{\epsilon}. \quad (C.17) \]

The integral can be performed analytically,
\[ I_{b3}(r = 2) = \frac{1}{16\pi^2} \left\{ B\left( e^{-\frac{N \pi}{4}}; \frac{1}{2} + 2\pi \gamma \epsilon, 0 \right) - B\left( e^{-\frac{\pi}{4}}; \frac{1}{2} + 2\pi \gamma \epsilon, 0 \right) - E(-\gamma \epsilon^2) + E(-\gamma N \epsilon) \right\}, \quad (C.18) \]
where the incomplete beta function and the exponential integral function, respectively, are defined as
\[ B(z; a, b) = \int_0^z dx \ x^{a-1} (1-x)^{b-1}, \]
\[ E(z) = -\int_{-z}^{\infty} dx \ \frac{e^{-x}}{x}. \quad (C.19) \]
Expanding $I_{b3}$ in $\epsilon$, one notices that only the second and third expression in Eq. (C.18) lead to $\epsilon$-divergences. Concretely, we obtain a logarithmic divergence,

$$I_{b3}(r = 2) = -\frac{1}{16\pi^2} \ln \epsilon + O(\epsilon^0).$$  

(C.20)

Collecting results, the divergences in the function $\tilde{g}_2$ in the weak magnetic field limit are

$$\tilde{g}_2 = -\frac{1}{16\pi^2 \sqrt{\gamma}} \frac{1}{\epsilon} - \frac{\sqrt{2} - 4}{32\pi} \zeta\left(\frac{3}{2}\right) \frac{1}{\sqrt{\epsilon}} - \frac{1}{16\pi^2} \ln \epsilon + O(\epsilon^0).$$  

(C.21)

The quark condensate in the chiral limit, according to Eqs. (3.15) and (3.17), features the series

$$S[\tilde{g}] = -\hat{c} \epsilon^2 \tilde{g}_2 + \frac{\hat{c}^2 \epsilon^4}{2!} \tilde{g}_3 - \frac{\hat{c}^3 \epsilon^6}{3!} \tilde{g}_4 + O(\tilde{g}_5),$$  

(C.22)

where

$$\hat{c} = 4\pi T^2 \gamma, \quad \gamma = \frac{l_6 - l_5}{12\pi} t^2.$$  

(C.23)

According to Eq. (C.14), the leading divergence in the functions $\tilde{g}_r$ is proportional to $\epsilon^{3-2r}$. Therefore each term in the above series gives rise to a contribution linear in $\epsilon$. All these terms have to be taken into account at the order we are operating. The series can be resummed with the result

$$S[\tilde{g}] = \frac{\sqrt{2} - 1}{2\sqrt{\pi}} \sqrt{\gamma} T^2.$$  

(C.24)

The quark condensate in the chiral limit – see Eqs. (3.15) and (3.17) – furthermore involves the other type of Bose functions $g_r(M, T, 0)$. The structure of the expansion in the mass parameter $M$ for the specific function $g_0(M, T, 0)$ has been analyzed in Refs. [43, 45] with the outcome

$$g_0(M, T, 0) = T^4 \left[ \frac{\pi^2}{45} - \frac{1}{12} \frac{M^2}{T^2} + \frac{1}{6\pi} \frac{M^3}{T^3} + \frac{(2\gamma_E - \frac{3}{2}) M^4}{32\pi^2} T^4 + \frac{1}{32\pi^2} \frac{M^4}{T^4} \ln \frac{M^2}{16\pi^2 T^2} \right. $$

$$\left. + 2\pi^{3/2} \sum_{n=3}^{\infty} \frac{(-1)^n}{n!} \left( \frac{M}{2\pi T} \right)^{2n} \Gamma(n - \frac{3}{2}) \zeta(2n - 3) \right] (T \gg M).$$  

(C.25)

With the recursion relation

$$g_{r+1} = -\frac{dg_r}{dM^2},$$  

(C.26)

the series for any other $g_r$ with $r = 1, 2, 3, \ldots$ can be derived.

In our case of interest, the relevant mass in these functions is $M_H$,

$$M_H^2 = \frac{\tilde{l}_6 - \tilde{l}_5}{48\pi^2} \frac{|qH|}{F^2} = \frac{16\pi^2}{3} \frac{1}{(\tilde{l}_6 - \tilde{l}_5) t^4 F^2 e^2},$$  

(C.27)
i.e., the mass of the charged pion that survives the chiral limit. We then find that the leading $\epsilon$-divergences in these functions are

$$g_r = \frac{(2r - 5)!! \gamma^{3/2-r}}{2^r - 2\pi^{r-1/2}} \epsilon^{3-2r}, \quad r = 2, 3, \ldots.$$  \hfill (C.28)$$

The series of kinematical functions $g_r$, as it occurs in the quark condensate,

$$S[g] = -\hat{c} \epsilon^2 g_2 + \frac{\hat{c}^2 \epsilon^4}{2!} g_3 - \frac{\hat{c}^3 \epsilon^6}{3!} g_4 + \mathcal{O}(g_5),$$  \hfill (C.29)$$

hence yields an infinite number of terms that are all linear in $\epsilon$. Resumming, we obtain

$$S[g] = \frac{1 - \sqrt{2}}{2\sqrt{\pi}} \sqrt{\gamma} \epsilon T^2.$$  \hfill (C.30)$$

This just cancels the contribution from $S[\tilde{g}]$, Eq. (C.24), such that there are no terms linear in $\epsilon$ in the quark condensate coming from here. The logarithmic contributions, however, that are present both in $g_2$ and $\tilde{g}_2$ do not cancel: in the sum we have

$$g_2 + \tilde{g}_2 = \frac{1}{16\pi^2} \ln \epsilon + \mathcal{O}(\epsilon^{-1/2}),$$  \hfill (C.31)$$
giving rise to a contribution $\epsilon^2 \ln \epsilon$ in the quark condensate.

Finally, the $\epsilon$-expansion for the functions $g_1(0, T, 0)$ and $\tilde{g}_1(0, T, H)$ that also appear in the quark condensate, Eqs. (3.15) and (3.17), has been provided in Refs. [36, 43]. For completeness we quote the result,

$$g_1(0, T, 0) = \frac{1}{12} T^2,$$  \hfill (C.32)$$
$$\tilde{g}_1(0, T, H) = -\left\{ \frac{|I_\perp|}{8\pi^{3/2}} \sqrt{\epsilon} - \frac{\ln 2}{16\pi^2} \epsilon + \frac{\zeta(3)}{384\pi^4} \epsilon^2 - \frac{7\zeta(7)}{98304\pi^8} \epsilon^4 + \mathcal{O}(\epsilon^6) \right\} T^2,$$

with

$$I_\perp = \int_0^\infty d\rho \rho^{-1/2} \left( \frac{1}{\sinh(\rho)} - \frac{1}{\rho} \right) \approx -1.516256.$$  \hfill (C.33)$$
