L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
ON MODULAR SIGNS OF HALF INTEGRAL WEIGHTS

BIN CHEN, JIE WU & YICHAO ZHANG

Abstract. In this paper, we consider the first negative eigenvalue of eigenforms of half-integral weight \( k + \frac{1}{2} \) and obtain an almost type bound.

1. Introduction

Let \( k \geq 3 \) be an integer and denote by \( \mathcal{S}_{k+1/2} = \mathcal{S}_{k+1/2}(4) \) the space of cusp forms of half-integral weight \( k + \frac{1}{2} \) on the congruence subgroup \( \Gamma_0(4) \). Let \( \mathcal{S}^{+,*}_{k+1/2} \) be Kohnen’s plus space in \( \mathcal{S}_{k+1/2} \) and \( \mathcal{S}^{+,*}_{k+1/2} \) be a basis of Hecke eigenforms of \( \mathcal{S}^{+,*}_{k+1/2} \). For \( \mathfrak{f} \in \mathcal{S}^{+,*}_{k+1/2} \), let \( a_{\mathfrak{f}}(n) \) be its \( n \)-th Fourier coefficient. For a positive square-free integer \( t \) with \( a_{\mathfrak{f}}(t) \neq 0 \), set \( a_{\mathfrak{f}}^T(n^2) = a_{\mathfrak{f}}(t)\overline{a_{\mathfrak{f}}(tn^2)}n^{-k+\frac{1}{2}} \), which is independent of \( t \) by Shimura’s theory [14]. See Section 2 for some basics on half-integral weight modular forms.

In this paper, we will investigate sign changes of the sequence \( \{a_{\mathfrak{f}}^T(n^2)\}_{n \geq 1} \). This problem has received much attention [10, 7, 9, 11, 2, 4]. In particular, denoting by \( n_{\mathfrak{f}} \) the smallest integer \( n \) such that

\[
(1.1) \quad a_{\mathfrak{f}}^T(n^2) < 0.
\]

Recently Chen and Wu [2] proved, by developing the method of [8], that for each \( \mathfrak{f} \in \mathcal{S}^{+,*}_{k+1/2} \), we have

\[
n_{\mathfrak{f}} \ll k^{9/10}
\]

uniformly for all \( k \geq 3 \), where the implied constant is absolute. The aim of this paper is to improve this bound on average. Our result is as follows.

Theorem 1. Let \( \nu \geq 1 \) be an integer and let \( \mathcal{P} \) be a set of prime numbers of positive density in the following sense:

\[
(1.2) \quad \sum_{\substack{z < p \leq 2z \ \text{prime} \ \mathcal{P} \ni p}} \frac{1}{p} \geq \frac{\delta}{\log z} \quad (z \geq z_0)
\]

for some constants \( \delta > 0 \) and \( z_0 > 0 \). Then there are two positive constants \( C \) and \( c \) such that for any \( \{\varepsilon_p\}_{p \in \mathcal{P}} \subset \{-1, 1\}^\mathcal{P} \), the number of the Hecke eigenforms \( \mathfrak{f} \in \mathcal{S}^{+,*}_{k+1/2} \) satisfying the condition

\[
(1.3) \quad \varepsilon_p a_{\mathfrak{f}}^T(p^{2\nu}) > 0 \quad \text{for} \quad C \log k < p \leq 2C \log k
\]

is bound by

\[
(1.4) \quad \ll k \exp(-c(\log k)/\log_2 k),
\]

where the implied constant are absolute and \( \log_2 := \log \log \).
For \( f \in \mathcal{S}_{k+1/2}^+ \), denote by \( n_f^* \) the smallest prime number \( p \) such that
\[
\Re a_f(p^2) < 0.
\]

We have trivially
\[
n_f \leq n_f^*
\]
for all \( f \in \mathcal{S}_{k+1/2}^+ \). Setting \( \mathcal{P} = \mathbb{P} \) (set of all prime numbers), \( \varepsilon_p = 1 \) for all \( p \in \mathcal{P} \) and \( \nu = 1 \) in Theorem 1, we immediately obtain the following result.

**Corollary 1.** There is an absolute positive constant \( c \) such that
\[
n_f^* \ll \log k
\]
for all \( f \in \mathcal{S}_{k+1/2}^+ \), except for \( f \) in an exceptional set with
\[
\ll k \exp(-c(\log k)/\log_2 k)
\]
elements, where the implied constants are absolute.

In the opposite direction, we have the following result.

**Theorem 2.** There are two absolute positive constants \( c_1 \) and \( c_2 \) such that
\[
\left| \left\{ f \in \mathcal{S}_{k+1/2}^+ : n_f^* \geq c_1 \sqrt{\log k \log_2 k} \right\} \right| \gg k \exp \left( -c_2 \sqrt{\log k / \log_2 k} \right),
\]
provided that \( k \) is large enough. Here the implied constant is absolute.

Our approach is rather flexible. In view of the half-integral weight newform theory [6, 13], our results could be further generalized to the case of \( \mathcal{S}_{k+1/2}^+ (4N, \chi) \), where \( k \geq 3 \) is an integer, \( N \geq 1 \) is square free, \( \chi \) is a quadratic character of Dirichlet and \( \mathcal{S}_{k+1/2}^+ (4N, \chi) \) is the set of all eigenforms in \( \mathcal{S}_{k+1/2}^+ (4N, \chi) \) — Kohnen’s plus subspace of cusp forms of half-integral weight \( k + 1/2 \) for \( \Gamma_0 (4N) \) with character \( \chi \).

## 2. Shimura Correspondence

In this section, we cover briefly Shimura’s theory on half-integral weight modular forms and the Shimura correspondence. Throughout let \( k \geq 3 \) be an integer and denote by \( \mathbb{P} \) the set of prime numbers.

Denote by \( \mathcal{H}_{2k} = \mathcal{H}_{2k}(1) \) and \( \mathcal{G}_{k+1/2} = \mathcal{G}_{k+1/2}(4) \) the space of cusp forms of weight \( 2k \) on the modular group \( \text{SL}_2(\mathbb{Z}) \) and that of cusp forms of weight \( k + \frac{1}{2} \) on the congruence subgroup \( \Gamma_0 (4) \), respectively. For \( f \in \mathcal{H}_{2k} \) and \( f \in \mathcal{G}_{k+1/2} \), denote their Fourier expansions at infinity by
\[
f(z) = \sum_{n \geq 1} a_f(n) e^{2\pi i nz}, \quad \tilde{f}(z) = \sum_{n \geq 1} a_t(n) e^{2\pi i nz}.
\]

Denote by \( \mathcal{G}_{k+1/2}^+ \) the subspace in \( \mathcal{G}_{k+1/2} \) of all forms \( \tilde{f} \) with \( a_t(n) = 0 \) for all \( n \) verifying \((-1)^k n \equiv 2, 3 \text{ (mod 4)}\). This subspace is called Kohnen’s plus space (cf. [6]).

For each positive integer \( n \), there is an Hermitian operator \( T_{2k}(n) \), the \( n \)-th Hecke operator, on \( \mathcal{H}_{2k} \), and \( \{T_{2k}(n) : n \geq 1\} \) has the structure of a commutative algebra, the *Hecke algebra* on \( \mathcal{H}_{2k} \). Consequently, there is a basis \( \mathcal{H}_{2k}^* \) of common eigenfunctions to all of \( T_{2k}(n) \) such that \( T_{2k}(n) f = a_f(n) f \) for each \( f \in \mathcal{H}_{2k}^* \). Elements of \( \mathcal{H}_{2k}^* \) are called normalized Hecke eigenforms in \( \mathcal{H}_{2k} \).
On the other hand, for each positive integer $n$, Shimura \cite[14]{Shimura} introduced the $n^2$-th Hecke operator $T_{k+1/2}(n^2)$ on $\mathcal{S}_{k+1/2}$, and the Hecke algebra of all Hecke operators is again commutative. Kohnen considered the restriction $T_{k+1/2}(n^2)$ of $T_{k+1/2}(n^2)$ to his plus space $\mathcal{S}^+_{k+1/2}$, and proved that $T_{k+1/2}(n^2)$ becomes an Hermitian operator. Therefore, there exists a basis of common eigenfunctions to all operators $T_{k+1/2}(n^2)$ in $\mathcal{S}^+_{k+1/2}$. We fix such a basis and denote it by $\mathcal{S}_{k+1/2}^+$. Note that the leading coefficient $f$ is not $a_f(1)$ in general, and normalizing the leading coefficient to be $1$ may lose the algebraicity of the Fourier coefficients. As a consequence, unlike the case of integral weight, there is no canonical choice for $\mathcal{S}_{k+1/2}^+$, but it causes no problems for our purpose.

Discovered by Shimura \cite{Shimura}, there exist liftings from Hecke eigenforms of half-integral weight to Hecke eigenforms of integral weight, the Shimura correspondence. Then Shintani \cite{Shintani} considered the restriction $T_{k+1/2}(n^2)$ of $T_{k+1/2}(n^2)$ to his plus space $\mathcal{S}^+_{k+1/2}$, and proved that $S_{k+1/2}$ depends on the choice of $S_{k+1/2}$, but it will not matter. Finally, Kohnen \cite[Theorem 1]{Kohnen} built an isomorphism between $\mathcal{S}_{k+1/2}^+$ and $\mathcal{H}_{2k}$ as Hecke modules. So in particular, as $k \to \infty$,

\begin{equation}
|\mathcal{S}^+_{k+1/2}| = |\mathcal{H}_{2k}| = \frac{1}{6}k + O(k^{1/2}).
\end{equation}

Now let us explain the Shimura correspondence explicitly. Fix a positive square-free integer $t$ and the Shimura correspondence $S_t$ is defined as follows: For each $f \in \mathcal{S}_{k+1/2}^+$, $f_t := S_t(f)$ has Fourier expansion at $\infty$

\begin{equation}
 f_t(z) = \sum_{n \geq 1} a_{f_t}(n)e^{2\pi inz},
\end{equation}

where

\begin{equation}
 a_{f_t}(n) := \sum_{d|n} \chi_t(d) d^{k-1} a_f \left( \left( \frac{n^2}{d^2} \right) \right), \quad \chi_t(d) := \left( \frac{-1}{d} \right).\n\end{equation}

Here $\left( \cdot \right)$ denotes the Kronecker symbol, an extension of Jacobi’s symbol to all integers (see \cite[14]{Shimura}, page 442). Then $f_t \in \mathcal{H}_{2k}$. Furthermore, if $f$ is a Hecke eigenform with eigenvalue $\omega_p$ for $T_{k+1/2}(p^2)$, then we may choose $t$ with $a_t(t) \neq 0$, and $S_t(f)$ becomes a Hecke eigenform in $\mathcal{H}_{2k}$ with leading coefficient $a_t(t)$. Actually,

\begin{equation}
 f(z) := a_t(t)^{-1} f_t(z) \in \mathcal{H}_{2k}^\ast
\end{equation}

and the $L$-function $L(s, f) = \prod_{p \in \mathcal{P}} (1 - \omega_p p^{-s} + p^{2k-1-2s})^{-1}$. It follows that the construction of $f$ from $f$ is independent of $t$, and $f$ is called the Shimura lift of $f$. Extending linearly from $\mathcal{S}_{k+1/2}^+$ to $\mathcal{S}_{k+1/2}$, we obtain the Shimura correspondence:

\begin{equation}
 \rho : \mathcal{S}_{k+1/2}^+ \to \mathcal{H}_{2k}, \quad f \mapsto f
\end{equation}

and $\rho$ gives an isomorphism between $\mathcal{S}_{k+1/2}^+$ and $\mathcal{H}_{2k}$ (we shall use this fact many times). Note that $\rho$ depends on the choice of $\mathcal{S}_{k+1/2}^+$, but it will not matter. Finally, Kohnen \cite{Kohnen} proved that $\rho$ is a finite linear combination of $S_t$'s.

According to \cite[(1.18)]{Shimura}, for a Hecke eigenform $f$ of weight $k + \frac{1}{2}$ and any square-free positive integer $t$, the multiplicativity for its Fourier coefficients takes the form

\begin{equation}
 a_f(tm^2) a_f(tn^2) = a_f(t) a_f(tm^2 n^2) \quad \text{if} \quad (m, n) = 1.
\end{equation}
If we write
\[(2.8) \quad a_i^s(n^2) := a_i(t)^{-1}a_i(tn^2)n^{-(k-1/2)}\]
and
\[(2.9) \quad \lambda_f(n) := a_i(t)^{-1}a_f(n)n^{-(2k-1)/2},\]
then the classical Hecke relation and (2.7) imply that the arithmetic functions \(n \mapsto \lambda_f(n)\) and \(n \mapsto a_i^s(n^2)\) are multiplicative. With such notation, the formula (2.4) can be written as
\[(2.10) \quad \lambda_f(n) = \sum_{d \mid n} \chi_t(d) a_i^s \left( \frac{n^2}{d^2} \right).\]
Since \(f \in H_{2k}^\ast\), \(\lambda_f(n)\) is real and satisfies the Deligne inequality
\[(2.11) \quad |\lambda_f(n)| \leq \tau(n)\]
for all integers \(n \geq 1\), where \(\tau(n)\) is the classical divisor function (see [3]). Let \(\mu(n)\) be the Möbius function. Applying the Möbius formula of inversion to (2.10), we can derive that
\[(2.12) \quad a_i^s(n^2) = \sum_{d \mid n} \mu(d) \chi_t(d) \lambda_f \left( \frac{n}{d} \right).\]

Thus \(a_i^s(n^2)\) is also real and (2.11) implies that
\[(2.13) \quad |a_i^s(n^2)| \leq \tau(n^2)\]
for all integers \(n \geq 1\).

Shimura’s theory on modular forms of half-integral weight holds in general. To obtain Kohnen’s isomorphism in general, one needs to develop a newform theory as Kohnen did in [6] for the case of level \(4N\) with \(N\) square-free.

### 3. Two large sieve inequalities

This section is devoted to present two large sieve inequalities on eigenvalues of modular forms, which will be one of the key tools in the proof of Theorem 1. The first large inequality is related to modular forms of integral weights, which is a particular case of [12, Theorem 1] with \(N = 1\).

**Lemma 3.1.** Let \(\nu \geq 1\) be a fixed integer and let \(\{b_p\}_{p \in \mathbb{P}}\) be a sequence of real numbers indexed by prime numbers such that \(|b_p| \leq B\) for some constant \(B\) and for all prime numbers \(p\). Then we have
\[(1.5) \quad \sum_{f \in \mathcal{S}_{2k}^\ast} \left| \sum_{P < p \leq Q} b_p \lambda_f(p^\nu) \right|^{2j} \ll_{\nu, k} k \left( \frac{384B^2\nu^2j}{P \log P} \right)^j + k^{10/11} \left( \frac{10BQ^{\nu/10}}{\log P} \right)^{2j}\]
uniformly for
\[B > 0, \quad j \geq 1, \quad k \geq 3, \quad 2 \leq P < Q \leq 2P.\]
The implied constant depends on \(\nu\) only.

For modular forms of half-integral weights, we can prove the same large sieve inequality.
Lemma 3.2. Let $\nu \geq 1$ be a fixed integer and let $\{b_p\}_{p \in \mathcal{P}}$ be a sequence of real numbers indexed by prime numbers such that $|b_p| \leq B$ for some constant $B$ and for all prime numbers $p$. Then we have
\[
\sum_{j \in \mathfrak{G}_{k+1/2}^+} \left| \sum_{P < p < Q} b_p a_j^*(p^{2\nu}) \right|^2 \leq \nu k \left( \frac{1536B^2\nu^2}{P \log P} \right)^j + k^{10/11} \left( \frac{20BQ^\nu / 10}{\log P} \right)^{2j}
\]
uniformly for $B > 0$, $j \geq 1$, $k \geq 3$, $2 \leq P < Q \leq 2P$.

The implied constant depends on $\nu$ only.

Proof. Taking $n = p^\nu$ in (2.12) gives us
\[
a_j^*(p^{2\nu}) = \lambda_f(p^\nu) - \frac{\chi_t(p)}{\sqrt{p}} \lambda_f(p^{\nu-1}).
\]
In view of the following facts that
\[
\left| \chi_t(p) \frac{\lambda_f(p^{\nu-1})}{\sqrt{p}} \right| \leq \frac{\nu}{\sqrt{p}} \quad \text{and} \quad (|a| + |b|)^m \leq (2|a|)^m + (2|b|)^m
\]
and of the Chebyshev estimate $\sum_{p \leq x} 1 \leq 10x / \log x$ ($x \geq 2$), we can derive that
\[
\left| \sum_{P < p < Q} b_p a_j^*(p^{2\nu}) \right|^2 \leq \left( \left| \sum_{P < p < Q} b_p \lambda_f(p^\nu) \right| + \left| \sum_{P < p < Q} b_p \chi_t(p) \frac{\lambda_f(p^{\nu-1})}{p^{3/2}} \right| \right)^2
\]
\[
\leq 2^{2j} \left| \sum_{P < p < Q} b_p \lambda_f(p^\nu) \right|^2 + \left( \frac{20B\nu}{\sqrt{P \log P}} \right)^{2j}.
\]

Since the Shimura correspondence (2.6) is a bijection between $\mathfrak{G}_{k+1/2}^+$ and $\mathfrak{H}_{2k}^*$, we can write
\[
\sum_{j \in \mathfrak{G}_{k+1/2}^+} \left| \sum_{P < p < Q} b_p a_j^*(p^{2\nu}) \right|^2 \leq 4^j \sum_{j \in \mathfrak{G}_{2k}^*} \left| \sum_{P < p < Q} b_p \lambda_f(p^\nu) \right|^2 + k \left( \frac{20B\nu}{\sqrt{P \log P}} \right)^{2j}.
\]

Now by applying Lemma 3.1, we have
\[
\sum_{j \in \mathfrak{G}_{k+1/2}^+} \left| \sum_{P < p < Q} b_p a_j^*(p^{2\nu}) \right|^2 \ll \nu k \left( \frac{1536B^2\nu^2}{P \log P} \right)^j + k^{10/11} \left( \frac{20BQ^\nu / 10}{\log P} \right)^{2j} + k \left( \frac{20B\nu}{\sqrt{P \log P}} \right)^{2j}
\]
uniformly for $B > 0$, $j \geq 1$, $k \geq 3$ and $2 \leq P < Q \leq 2P$. This implies the required inequality since the third term on the right-hand side can be absorbed by the first one. \(\square\)

4. Proof of Theorem 1

Define
\[
\mathfrak{G}_{k+1/2}^+(P) := \{ f \in \mathfrak{G}_{k+1/2}^+ : \varepsilon_p a_j^*(p^{2\nu}) > 0 \text{ for } p \in (P, 2P] \cap \mathcal{P} \}.
\]
It suffices to prove that there are two positive constants $C = C(\nu, \mathcal{P})$ and $c = c(\nu, \mathcal{P})$ such that
\[
|\mathfrak{G}_{k+1/2}^+(P)| \ll \nu k \exp(-c(\log k) / \log_2 k)
\]
ouniformly for $k \geq k_0$ and $C \log k \leq P \leq (\log k)^{10}$ for some sufficiently large number $k_0 = k_0(\nu, \mathcal{P})$. 
For $1 \leq \mu \leq \nu$, define
\[
\mathcal{G}_{k+1/2}^{+,\ast,\mu}(P) := \left\{ f \in \mathcal{S}_{k+1/2}^{+,\ast} : \sum_{p \in \mathbb{P}, 2p \cap \mathbb{P}} \frac{\lambda_f(p^{2\mu})}{p} \geq \frac{\delta}{4\nu \log P} \right\}.
\]
Take
\[
\nu = 2\mu, \quad Q = 2P \quad \text{and} \quad b_p = \begin{cases} 1 & \text{if } p \in \mathbb{P} \\ 0 & \text{otherwise} \end{cases}
\]
in Lemma 3.2. Then we get
\[
\left( \frac{\delta}{4\nu \log P} \right)^{2j} |\mathcal{G}_{k+1/2}^{+,\ast,\mu}(P)| \leq \sum_{f \in \mathcal{S}_{k+1/2}^{+,\ast}} \left| \sum_{p \in \mathbb{P}, 2p \cap \mathbb{P}} b_p \frac{\lambda_f(p^{2\mu})}{p} \right|^{2j} \ll k \left( \frac{1536\mu^2 j}{P \log P} \right)^{j} + k^{10/11} \left( \frac{10(2P)^{\mu/5}}{\log P} \right)^{2j}.
\]
Hence,
\[
|\mathcal{G}_{k+1/2}^{+,\ast,\mu}(P)| \ll k \left( \frac{3456\nu^4 j \log P}{\delta^2 P} \right)^{j} + k^{10/11} P^{\nu j},
\]
provided $P \geq 200$.

Let
\[
b_p = \begin{cases} \varepsilon_p & \text{if } p \in \mathbb{P} \\ 0 & \text{otherwise}. \end{cases}
\]
From the definition of $\mathcal{G}_{k+1/2}^{+,\ast,\mu}(P)$, (2.13) and Lemma 3.2, we deduce that
\[
\sum_{f \in \mathcal{S}_{k+1/2}^{+,\ast}(P)} \left| \sum_{p \in \mathbb{P}, 2p \cap \mathbb{P}} \frac{\mathfrak{a}_f^{*}(p^{2\nu})^2}{p} \right|^{2j} \leq (2\nu + 1) \sum_{f \in \mathcal{S}_{k+1/2}^{+,\ast}} \left| \sum_{p \in \mathbb{P}, 2p \cap \mathbb{P}} b_p \frac{\mathfrak{a}_f^{*}(p^{2\nu})}{p} \right|^{2j} \ll_{\nu} k \left( \frac{1536\nu^2 j}{P \log P} \right)^{j} + k^{10/11} \left( \frac{20Q^{\nu/10}}{\log P} \right)^{2j}
\]
\[
\ll_{\nu} k \left( \frac{1536\nu^2 j}{P \log P} \right)^{j} + k^{10/11} P^{\nu j/2}.
\]
In view of (2.10), the Deligne inequality and the Hecke relation, it follows that
\[
\mathfrak{a}_f^{*}(tp^{2\nu})^2 \geq 1 + \lambda_f(p^2) + \cdots + \lambda_f(p^{2\nu}) - 4\nu^2/\sqrt{p}.
\]
The left-hand side of (4.3) is
\[
\geq \sum_{f \in \mathcal{S}_{k+1/2}^{+,\ast}(P) \setminus \bigcup_{\mu=1}^{\nu} \mathcal{S}_{k+1/2}^{+,\ast,\mu}(P)} \left( \sum_{p \in \mathbb{P}, 2p \cap \mathbb{P}} \frac{1}{p} - \sum_{1 \leq \mu \leq \nu} \left| \sum_{p \in \mathbb{P}, 2p \cap \mathbb{P}} \frac{\lambda_f(p^{2\mu})}{p} \right| - \frac{4\nu^2}{\sqrt{P \log P}} \right)^{2j}
\]
\[
\geq \sum_{f \in \mathcal{S}_{k+1/2}^{+,\ast}(P) \setminus \bigcup_{\mu=1}^{\nu} \mathcal{S}_{k+1/2}^{+,\ast,\mu}(P)} \left( \sum_{p \in \mathbb{P}, 2p \cap \mathbb{P}} \frac{1}{p} - \frac{\delta}{4 \log P} - \frac{4\nu^2}{\sqrt{P \log P}} \right)^{2j}.
\]
Using the hypothesis (1.2), we infer that
\[
\sum_{P < p \leq 2P} \frac{1}{P} - \frac{\delta}{4\log P} - \frac{4\nu^2}{\sqrt{P}\log P} \geq \frac{\delta}{\log P} - \frac{\delta}{4\log P} - \frac{\delta}{4\log P} = \frac{\delta}{2\log P},
\]
provided \( P \geq 256\nu^4\delta^{-2} \).

Combining these estimates with (4.3), we conclude that
\[
\left| \mathcal{S}_{k+1/2}^{-}(P) \setminus \bigcup_{\mu=1}^{\nu} \mathcal{S}_{k+1/2}^{+,\mu}(P) \right| \ll_{\nu} k \left( \frac{1536\nu^2 j \log P}{\delta^2 P} \right)^j + k^{10/11} P^{\nu j}.
\]
Together with (4.2), it implies
\[
(4.4) \quad \left| \mathcal{S}_{k+1/2}^{-}(P) \right| \ll k \left( \frac{3456\nu^4 j \log P}{\delta^2 P} \right)^j + k^{10/11} P^{\nu j}
\]
uniformly for
\[ j \geq 1, \quad 2 \mid k \geq 3, \quad C \log k \leq P \leq (\log k)^{10}. \]

Take
\[ j = \left[ \frac{\delta^* \log k}{\log P} \right] \]
where \( \delta^* = \delta^2/(10(\nu + 1))^4 \). We can ensure \( j > 1 \) once \( k_0 \) is chosen to be suitably large. A simple computation gives that
\[
\left( \frac{3456\nu^4 j \log P}{\delta^2 P} \right)^j \ll \exp(-c(\log k)/\log_2 k)
\]
for some positive constant \( c = c(\nu, P) \) and \( P^{\nu j} \ll k^{1/1000} \), provided that \( k_0 \) is large enough. Inserting them into (4.4), we get (4.1) and complete the proof. \( \square \)

5. Proof of Theorem 2

Since the proof of Theorem 2 is rather similar to that of [8, Theorem 4], we shall only point out the differences.

It is well known that the Chebychev functions \( X_n, n \geq 0 \), defined by
\[
(5.1) \quad X_n(\theta) := \frac{\sin((n+1)\theta)}{\sin \theta} \quad (\theta \in [0, \pi])
\]
form an orthonormal basis of \( L^2([0, \pi], \mu_{ST}) \). Hence, for any integer \( \omega \geq 1 \), the functions of the type
\[
(\theta_1, \ldots, \theta_\omega) \mapsto \prod_{1 \leq j \leq \omega} X_{n_j}(\theta_j)
\]
for \( n_j \geq 0 \), form an orthonormal basis of \( L^2([0, \pi]^\omega, \mu_{ST}^\omega) \).

For any \( f \in \mathcal{H}_{k_0}^0 \) and prime \( p \), the Deligne inequality (2.11) implies that there is a real number \( \theta_f(p) \in [0, \pi] \) such that
\[
(5.2) \quad \lambda_f(p) = 2 \cos \theta_f(p).
\]
Lemma 5.1. Let $k \in \mathbb{N}, s \in \mathbb{N}$ and $z \geq 2$ be a real number. For any prime $p \leq z$, let
\[
Y_p(\theta) := \sum_{0 \leq j \leq s} \hat{y}_p(j)X_j(\theta)
\]
be a “polynomial” of degree $\leq s$ expressed in the basis of Chebychev functions on $[0, \pi]$. Then we have
\[
\sum_{f \in \mathcal{M}_{k}^{s}} \omega_f \prod_{p \leq z} Y_p(\theta_f(p)) = \prod_{p \leq z} \hat{y}_p(0) + O(C^{\pi(z)}D^{x^2}k^{-5/6}),
\]
where $\|f\|^2$ is the Petersson norm of $f$,
\[
\omega_f := (4\pi)^{-(k-1)}\Gamma(k-1)\|f\|^{-2}, \quad C := \max_{p,j} |\hat{y}_p(j)|,
\]
and $D \geq 1$ and the implied constant is absolute.

Let $z \geq 2$ be a parameter to be determined later and $L \equiv 3 \pmod{4}$ be a positive integer. According to [1, Theorem 7] with the choice of parameters $N = \pi(z)$ (the number of primes $p \leq z$) and $u_n = 0, v_n = \frac{1}{z}$ for all $n \leq \pi(z)$, we can get two explicit trigonometric polynomials on $[0, 1]^\pi(z)$, denoted $A_L(x)$, $B_L(x)$, such that
\[
A_L(\theta/\pi) - B_L(\theta/\pi) \leq \prod_{p \leq z} 1_{[0, \frac{z}{4}]}(\theta_p)
\]
for all $\theta := (\theta_p)_{p \leq z} \in [0, \pi]^\pi(z)$, where $1_{[0, \frac{z}{4}]}(t)$ is the characteristic function of $[0, \frac{z}{4}] \subset [0, \pi]$ (since $(v_n - u_n)(L + 1) = \frac{1}{2}(L + 1)$ is a positive integer, we are in the situation $\Phi_{u,v} \in \mathcal{B}_N(L)$ of loc. cit.). Moreover, $A_L(\theta/\pi)$ is a product of polynomials over each variable, and $B_L(\theta/\pi)$ is a sum of $\pi(z)$ such products.

In view of (5.2) and (3.1) with $\nu = 1$, we have the following implicit relations
\[
\theta_f(p) \in [0, \frac{1}{4}\pi] \iff \lambda_f(p) \geq \sqrt{2} \Rightarrow \lambda_f(p)^{2} \geq 0.
\]
Combining these with (5.3), we can write, with the notation $\theta_f := (\theta_f(p))_{p \leq z}$,
\[
\sum_{f \in \mathcal{M}_{k}^{s}, a_f(p^{2}) \geq 0 \text{ for } p \leq z} \omega_f \geq \sum_{f \in \mathcal{M}_{k}^{s}, \lambda_f(p) \geq \sqrt{2} \text{ for } p \leq z} \omega_f \geq \sum_{f \in \mathcal{M}_{k}^{s}} \omega_f \prod_{p \leq z} 1_{[0, \frac{z}{4}]}(\theta_f(p)) \geq \sum_{f \in \mathcal{M}_{k}^{s}} \omega_f (A_L(\theta_f/\pi) - B_L(\theta_f/\pi)).
\]

The next lemma is an analogue of [8, Lemma 3.2].

Lemma 5.2. With notation as above, we have:
(a) For any $\epsilon \in (0, \frac{1}{4})$, there exist constants $c > 0$ and $L_0 \geq 1$ such that the contribution $\Delta$ of the constant terms of the Chebychev expansions of $A_L(\theta/\pi)$ and $B_L(\theta/\pi)$ satisfies
\[
\Delta \geq \left(\frac{1}{4} - \epsilon\right)^{\pi(z)},
\]
if $L \equiv 3 \pmod{4}$ is the smallest integer $\geq \max\{c\pi(z), L_0\}$.
(b) All the coefficients in the expansion in terms of Chebychev functions of the factors in $A_L(\theta/\pi)$ or in the terms of $B_L(\theta/\pi)$ are bounded by 1.
(c) The degrees, in terms of Chebychev functions, of the factors of $A_L(\theta/\pi)$ and of the terms of $B_L(\theta/\pi)$, are $\leq 2L$. 
Take $L$ as in Lemma 5.2(a) (we can obviously assume $L \geq L_0$, since otherwise $z$ is bounded). Since $A_L(\theta/\pi)$ is a product of polynomials over each variable and $B_L(\theta/\pi)$ is a sum of $\omega$ such products, we can now apply Lemma 5.1 to the terms on the right-hand side of (5.4). Noticing that Lemma 5.2(b) implies $C \leq 1$, we have

$$
\sum_{f \in \mathcal{S}_{k+1/2}^+\mathcal{S}_{k+1/2}^+} \omega_f \geq \sum_{f \in \mathcal{S}_{k+2}^+} \omega_f \left( A_L(\theta_f/\pi) - B_L(\theta_f/\pi) \right)
$$

(5.5)

$$
= \Delta + O(D^{2\pi(z)}k^{-5/6}).
$$

Fixing $\varepsilon \in (0, \frac{1}{8})$, taking $z = c_1 \sqrt{(\log k) \log_2 k}$ and using Lemma 5.2, we have

$$
\Delta + O(D^{2\pi(z)}k^{-5/6}) \geq (\frac{1}{4} - \varepsilon)^{\pi(z)} + O(D^{2\pi(z)}k^{-5/6})
$$

$$
\gg \exp \left( - (c_2/2) \sqrt{\log k} / \log_2 k \right).
$$

Combining it with (5.5) and noticing that $a_i(p^2) \geq 0$ for $p \leq z$ implies $n_i^* > z$, we find that

$$
\sum_{n_i^* > c_1 \sqrt{(\log k) \log_2 k}} \omega_f \gg \exp \left( - (c_2/2) \sqrt{\log k} / \log_2 k \right).
$$

Now the required result follows from this inequality thanks to the well-known bounds $\omega_f \ll (\log k)/k$.

**Acknowledgement.** We began working on this paper during a visit of the first author at Université de Lorraine during the academic year 2018-19. He would like to thank the institute for the pleasant working conditions. This work is supported in part by the National Natural Science Foundation of China (Grant Nos. 11771121, 11971370 and 11871175).
