Abstract: We propose a model of quark and lepton mixing based on the tetrahedral $A_4$ family symmetry with quark-lepton unification via the tetra-colour Pati-Salam gauge group $SU(4)_{PS}$, together with $SU(2)_L \times U(1)_R$. The “tetra-model” solves many of the flavour puzzles and remarkably gives ten predictions at leading order, including all six PMNS parameters. The Cabibbo angle is approximately given by $\theta_C \approx 1/4$, due to the tetra-vacuum alignment $(1, 4, 2)$, providing the Cabibbo connection between quark and lepton mixing. Higher order corrections are responsible for the smaller quark mixing angles and CP violation and provide corrections to the Cabibbo and lepton mixing angles and phases. The tetra-model involves an SO(10)-like pattern of Dirac and heavy right-handed neutrino masses, with the strong up-type quark mass hierarchy cancelling in the see-saw mechanism, leading to a normal hierarchy of neutrino masses with an atmospheric angle in the first octant, $\theta_{13}^l = 40^\circ \pm 1^\circ$, a solar angle $\theta_{12}^l = 34^\circ \pm 1^\circ$, a reactor angle $\theta_{13}^l = 9.0^\circ \pm 0.5^\circ$, depending on the ratio of neutrino masses $m_2/m_3$, and a Dirac CP violating oscillation phase $\delta_l = 260^\circ \pm 5^\circ$.

ArXiv ePrint: 1311.3295
1 Introduction

The discovery of a Higgs boson at the LHC [1, 2] provides convincing evidence for the Standard Model (SM) picture of electroweak symmetry broken by the vacuum expectation value (VEV) of a doublet of complex scalars. In the SM, the Higgs doublet is also responsible for quark and charged lepton masses and quark mixing via the Yukawa couplings to fermions. However the SM offers no insight into pattern of such Yukawa couplings, nor into the origin and nature of neutrino mass. Indeed it is worth recalling that the flavour sector of the SM involves at least twenty undetermined parameters, including ten parameters in the quark sector comprising the six quark masses, the three quark mixing angles and the phase describing CP violation. The lepton sector involves at least a further ten physical parameters, comprising the three charged lepton masses, three neutrino masses, three lepton mixing angles and the phase describing CP violation in the lepton sector. If neutrinos are Majorana, then there will be another two CP violating leptonic phases. The most recent best fit values of leptonic mixing parameters are [3]: $\theta_{12} = 34^\circ \pm 0.8^\circ$, $\theta_{23} = 42^\circ \pm 2^\circ$ or $\theta_{23} = 50^\circ \pm 2^\circ$, $\theta_{13} = 9^\circ \pm 0.4^\circ$, $\delta = 270^\circ \pm 70^\circ$, where the errors quoted are one sigma ranges.
Following the discovery of neutrino mass and mixing in 1998, there has been a major discovery in neutrino physics almost every year (for an up to date review see e.g. [4]). For example, in 2012 the reactor angle was measured for the first time, with the latest central value measured by Daya Bay being $\theta_{13}^l \approx 8.7^\circ$ [5]. The measurement of the reactor angle excluded many neutrino mixing models, and led to new model building strategies based on discrete family symmetries as reviewed in [4]. The discoveries in neutrino physics have enriched the flavour puzzle, raising new questions such as the smallness of neutrino masses compared to charged fermion masses, the stronger hierarchy of charged fermion masses compared to neutrino masses and the smallness of the quark mixing angles compared to lepton mixing angles, apart from the Cabibbo angle $\theta_C$ which is of similar size to the reactor angle, for example $\theta_{13}^l \approx \theta_C/\sqrt{2}$ [6], which may be combined with tri-bimaximal (TB) mixing [7]. These new flavour puzzles are in addition to the long standing questions such as the similarity of charged lepton masses to down-type quark masses and the stronger hierarchy of up quark masses compared to down quark masses. The origin of CP violation in both the quark and (so far unmeasured) lepton sectors also remains a mystery.

The see-saw mechanism [8–11] sheds light on the smallness of neutrino masses but can increase the parameter count considerably due to an undetermined right-handed neutrino Majorana mass matrix. In the diagonal right-handed neutrino and charged lepton basis (the so-called flavour basis) there is an undetermined neutrino Yukawa matrix. Without the see-saw mechanism, the SM involves three charged fermion Yukawa matrices but these are non-physical and basis dependent quantities. However, in theories of flavour beyond the SM, the choice of basis may well have physical significance and, in a certain basis defined by the theory, the Yukawa matrices may take simple forms, leading to some predictive power of the model as a result.

Recently we proposed a model of leptons [12, 13] based on the see-saw mechanism in which the number of parameters in the lepton sector was dramatically reduced. In the flavour basis, the right-handed neutrino mainly responsible for the atmospheric neutrino mass has couplings to $(\nu_e, \nu_\mu, \nu_\tau)$ proportional to $(0, 1, 1)$ and the right-handed neutrino mainly responsible for the solar neutrino mass has couplings to $(\nu_e, \nu_\mu, \nu_\tau)$ proportional to $(1, 4, 2)$, with a relative phase $\eta = \pm 2\pi/5$, where the couplings and phase originated from vacuum alignment with $A_4$ and $Z_5$ discrete symmetries. The model involved two right-handed neutrinos as a limiting case of sequential dominance (SD) [14–18]. The model predicted lepton mixing angles which agreed very well with the best fit values for a normal neutrino mass hierarchy, together with predictions for the CP violating phases, whose sign depended on the sign of the phase $\eta = \pm 2\pi/5$. The goal of the present paper is to extend the above model of leptons to the quark sector, in such a way as to preserve the successful predictions in the lepton sector, thereby providing a complete model of quark and lepton masses and mixing.

In this paper we propose a model of quark and lepton mixing based on the tetrahedral $A_4$ discrete family symmetry and the tetra-colour Pati-Salam (PS) gauge group SU(4)$_{PS}$ [19], together with SU(2)$_L \times U(1)_R$, where we refer to this group as A4SU421. The A4SU421 model with the above tetra-vacuum alignment $(1, 4, 2)$ will be referred to as the “tetra-model” for brevity. The unification of quarks and leptons in terms of A4SU421
Figure 1. The $A_4 SU(4)$ unification of quarks and leptons in the “tetra-model”. The left diagram depicts quark-lepton-family unification of the 24 left-handed quarks and leptons denoted collectively as $Q$ into a single $(3, 4, 2, 0)$ multiplet of $A_4 SU(4)$. The right diagram shows the 24 right-handed quarks and leptons which form six $A_4$ singlets, $U_i$ and $D_i$, distinguished by $Z_5$ and $Z_3$, with quarks and leptons unified in each multiplet.

is depicted in figure 1. The model involves $U(1)_R$, rather than $SU(2)_R$, used in previous models [20], in order to allow diagonal charged lepton and down quark Yukawa matrices together with off-diagonal neutrino and up quark Yukawa matrices. Quark mixing then arises completely from the up quark Yukawa matrix, which is equal to the neutrino Yukawa up to Clebsch-Gordan coefficients. The diagonal charged lepton and down quark Yukawa matrices are also equal up to Clebsch-Gordan coefficients due to the $SU(4)_{PS}$. The Cabibbo angle is predicted to be $\theta_C \approx 1/4$ due to the tetra-vacuum alignment in the second column $(1, 4, 2)$, which is common to the neutrino and up Yukawa matrices, providing a Cabibbo connection between quark and lepton mixing. The tetra-model predicts an $SO(10)$-like pattern of Dirac and heavy right-handed neutrino masses, with the strong up-quark mass hierarchy cancelling in the see-saw mechanism, leading to a normal neutrino mass hierarchy.

It is worth discussing how the tetra-model compares to some other recent attempts to explain both quark and lepton mixing as a result of discrete family symmetry, following the measurement of the reactor angle. Models can be classified as direct, semi-direct or indirect, depending to what extent a subgroup of the discrete family symmetry can be identified with the Klein symmetry of the neutrino sector [4]. In several of these models quarks are included via SU(5) unification, but typically vacuum alignment does not determine the quark mixing angles. However, in a purely symmetry approach, the direct approach has been extended to the quark sector, where a subgroup of the discrete family symmetry is used to constrain also the quark mixing angles, in analogy with the procedure followed for the Klein symmetry in the neutrino sector [21–23], but no realistic model has been proposed. In some such approaches [22, 23], the symmetry groups can be quite large, for example $\Delta(6n^2)$ for large values of $n$ [24].

Here we follow the indirect approach where small discrete family symmetries such as $A_4$ are used to facilitate interesting vacuum alignments, rather than as the direct origin of the Klein symmetry. Including the SD mechanism [14–18] and vacuum alignment, vari-
ous forms of constrained sequential dominance (CSD) have been considered based on the atmospheric neutrino alignment (0, 1, 1) but with different forms of solar neutrino alignment: original CSD [25] involved a solar alignment (1, 1, −1) yielding tri-bimaximal (TB) mixing; CSD2 [26, 27] involved a solar alignment (1, 2, 0) and hence a small reactor angle; CSD3 [13] involved solar alignment (1, 3, 1) with an acceptable reactor angle but maximal atmospheric mixing; CSD4 [12] with the tetra-alignment (1, 4, 2) adopted here predicts best fit lepton angles with a normal hierarchy. By unifying leptons with quarks, we show here for the first time that CSD4 can also successfully predict the Cabibbo angle.

The layout of the remainder of the paper is as follows. In section 2 we introduce the tetra-model, and show how the vacuum alignments imply the pattern of Yukawa matrices described above, in the down, up and Majorana sectors. In section 3 we collect together all the Yukawa matrices and discuss the leading order predictions of the model, first qualitatively, then giving the quantitative predictions in the lepton sector in the presence of the third right-handed neutrino leading to a non-zero lightest neutrino mass. In section 4 we discuss the higher order corrections to the model, responsible for the small quark mixing angles and CP violation, first studying the operators, then the effect of these operators on the Yukawa matrices and hence on the predictions for all quark and lepton masses and mixing angles. Section 5 concludes the paper.

2 The tetra-model

2.1 Overview

The model is based on tetrahedral $A_4$ family symmetry combined with the tetra-colour Pati-Salam gauge group $SU(4)_{PS}$ together with $SU(2)_L \times U(1)_R$,

$$A_4 \times SU(4)_{PS} \times SU(2)_L \times U(1)_R,$$

where we refer to this group as $A_4SU421$. Formally $U(1)_R$ may be identified as the diagonal subgroup of the Pati-Salam right-handed gauge group $SU(2)_R$ with $R = T^3_R$, the third generator of $SU(2)_R$. However we only assume a $U(1)_R$ gauge group since we require diagonal down and charged lepton Yukawa matrices together with off-diagonal up and neutrino Yukawa matrices, and this is very difficult to achieve if the full $SU(2)_R$ is respected. For the same reason it is not possible to embed the model into $SO(10)$. An additional reason why the $SO(10)$ embedding is not possible is that the left-handed and right-handed quarks and leptons transform differently under $A_4$, as discussed below.

The left-handed quarks and leptons are unified into the single multiplet $Q$ while the (CP conjugated) right-handed fields $U^c_i$ and $D^c_i$ are $A_4$ singlets, transforming under $A_4SU421$ as,

$$Q = (3, 4, 2, 0), \quad U^c_i = (1, 3, 1, -1/2), \quad D^c_i = (1, 3, 1, 1/2).$$

The unification of quarks and leptons has already been depicted in figure 1. The full list of fields which transform under the $A_4$ and/or the Pati-Salam group are shown in table 1. Clearly above tetra-model cannot be embedded into $A_4 \times SO(10)$ since different components
of the 16-dimensional representation of SO(10) transform differently under $A_4$.

The partial Pati-Salam gauge group is broken to the SM,

$$SU(4)_{PS} \times U(1)_R \rightarrow SU(3)_C \times U(1)_{B-L} \times U(1)_R \rightarrow SU(3)_C \times U(1)_Y,$$

(2.3)

by PS Higgs, $\mathcal{H}_U = (H_U^c, H_N^c)$ and $\overline{\mathcal{H}}_U = (\overline{H}_U^c, \overline{H}_N^c)$, which acquire VEVs in the “right-handed neutrino” directions $\langle H_N^c \rangle = \langle \overline{H}_N^c \rangle$. If the breaking occurs at high scales, close to $2 \times 10^{16}$ GeV, then supersymmetric gauge coupling unification of the SM gauge couplings is maintained. The preserved hypercharge generator is given by,

$$Y = \frac{B - L}{2} + R.$$

(2.4)

The choice of gauge group SU(4)21 has been recently considered in [28], although without any discrete family symmetry such as $A_4$ considered here. It is worth pointing out that in the tetra model none of the Higgs fields carry any $A_4$ charges, while none of the flavons carry any SU(4)21 charges. This means that, in the absence of any other flavour symmetries, the flavon potential relevant for $A_4$ breaking is independent of the SU(4)21 breaking potential, where the latter was considered in [28] for a non-supersymmetric model. The potential for the minimal supersymmetric SU(4)22 potential has been considered in [29].

Below the PS scale, $h_D \sim (15, 2, -1/2)$ will yield a Higgs doublet with the same quantum numbers as $h_d \sim (1, 2, -1/2)$. When the resulting mass matrix of Higgs doublets is diagonalised, there will be a single low energy down-type Higgs doublet consisting of a mixture of the Higgs doublet contained in $h_D \sim (15, 2, -1/2)$ and $h_d \sim (1, 2, -1/2)$. This is of course a well known effect [30]. A similar mass mixing may also arise between the Higgs doublet in $h_U \sim (15, 2, 1/2)$ and $h_u \sim (1, 2, 1/2)$ leading to a single low energy up-type Higgs doublet. We therefore expect two low energy electroweak Higgs doublets, one up-type and one down-type, as in the MSSM.

However the use of such minimal Higgs potentials has been called into question in theories where some of the Higgs fields transform under both GUT and flavour symmetries [31]. In the present model it will turn out that $h_D \sim (15, 2, -1/2)$ and $h_U \sim (15, 2, 1/2)$ will transform under $Z_3^U$ and $Z_5^U$ flavour symmetries, and these charges will require the standard Higgs potentials to be modified. In the present model it will turn out that the combination of Higgs fields $h_D \Sigma_{15}$ has exactly the same quantum numbers under all symmetries.
(including flavour symmetries) as $h_d$. Similarly the combination of Higgs fields $h_u \Sigma'_15$ has exactly the same quantum numbers under all symmetries as $h_u$. Therefore, the standard Higgs potentials may be used together with extra non-renormalisable terms obtained by replacing $h_d \rightarrow h_D \Sigma_15$ and $h_u \rightarrow h_U \Sigma'_15$. When $\Sigma_15$ and $\Sigma'_15$ develop vacuum expectation values, the extra terms yield the desired Higgs mixing as in the standard mechanisms without flavour symmetry.

The $A_4$ is broken by the VEVs of six triplet flavons $\phi_U^c_i$ and $\phi_D^c_i$, which couple in a one-one correspondence with $U^c_i$ and $D^c_i$. The remaining fields are messengers entering the diagrams in figure 2 as discussed later.

### 2.2 CSD4 vacuum alignments

The structure of the Yukawa matrices depends on the so-called CSD4 vacuum alignments which were first derived in \[12\],

\begin{equation}
\langle \phi_U^c_1 \rangle = \frac{v_U^c}{\sqrt{2}} \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}, \quad \langle \phi_U^c_2 \rangle = \frac{v_U^c}{\sqrt{21}} \begin{pmatrix} 1 \\ 4 \\ 2 \end{pmatrix}, \quad \langle \phi_U^c_3 \rangle = \frac{v_U^c}{1} \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}, \quad (2.5)
\end{equation}

and

\begin{equation}
\langle \phi_D^c_1 \rangle = \frac{v_D^c}{1} \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \quad \langle \phi_D^c_2 \rangle = \frac{v_D^c}{1} \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}, \quad \langle \phi_D^c_3 \rangle = \frac{v_D^c}{1} \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}. \quad (2.6)
\end{equation}

The mechanism for the vacuum alignment, especially the tetra-alignment $(1, 4, 2)$, relies mainly on orthogonality of flavons as discussed in \[12\]. It is noteworthy that we impose a CP symmetry which is spontaneously broken by VEVs of the flavons. Due to the $Z_5$ symmetries, the $\phi_U^c_i$ flavons can only acquire a discrete choice of overall phase corresponding to some multiple of $2\pi/5$. Similarly, due to the $Z_3$ symmetries, the $\phi_D^c_i$ flavons can only acquire a discrete choice of overall phase corresponding to some multiple of $2\pi/3$. As in \[12\], we will select all the phases of the triplet flavons to be all zero, with CP violation originating from the phases of the singlet flavons $\xi_i$ as discussed later.

At leading order, the CSD4 vacuum alignment of the flavons, together with operators of the form $(\phi_U^c_i \cdot Q) U^c_i$ and $(\phi_D^c_i \cdot Q) D^c_i$, imply that the Yukawa matrices (in LR convention) are constructed from the column vectors above.

The up and neutrino Yukawa matrices are obtained from $(\phi_U^c_i \cdot Q) U^c_i$ by sticking together the three column vectors in eq. (2.5),

\begin{equation}
Y^\nu \sim Y^u \sim \begin{pmatrix} 0 & b & 0 \\ a & 4b & 0 \\ a & 2b & c \end{pmatrix}, \quad (2.7)
\end{equation}

where each column is multiplied by a different constant of proportionality. The Yukawa matrices are not expected to be exactly equal due to Clebsch-Gordan coefficients, as discussed later.
The down and charged lepton Yukawa matrices are similarly obtained from \((\phi_{D_i}, Q)D_i^c\) by amalgamating the three column vectors in eq. (2.6) and are hence diagonal,

\[
Y^d \sim Y^e \sim \begin{pmatrix}
y_d & 0 & 0 \\
0 & y_s & 0 \\
0 & 0 & y_b
\end{pmatrix},
\]

As mentioned above, the Yukawa matrices are not expected to be exactly equal due to Clebsch-Gordan coefficients, as discussed later.

The quark-lepton unification implies that the second column \((1, 4, 2)^T\) of the neutrino Yukawa matrix is equal to that of the up quark Yukawa matrix and hence predicts a Cabibbo angle approximately equal to \(1/4\). The third column (approximately decoupled from the see-saw mechanism) is proportional to \((0, 0, 1)^T\) at leading order giving the top quark Yukawa coupling. Higher order corrections modify the leading order predictions and are responsible for the other quark mixing angles and CP violation.

As discussed in the following subsections, the model employs other auxiliary \(Z_5\) and \(Z_3\) symmetries in order to ensure the one-one correspondence of the couplings of the flavons \(\phi_{U_i}^c\) and \(\phi_{D_i}^c\) with \(U_i^c\) and \(D_i^c\) in the Yukawa operators. These symmetries also predict Clebsch-Gordan relations between the down quark and charged lepton masses, as well as the up quark mass hierarchy, with the charges cancelling in the see-saw mechanism, leading to a mild normal neutrino mass hierarchy. However right-handed neutrino masses are predicted to be very hierarchical, being proportional to the squares of up-type quark masses, which is another consequence of quark-lepton unification.

### 2.3 The down sector

We first consider the down sector, where the postulated \(Z_5\) symmetries and charges are shown in table 2. The \(Z_3^{D_i}\) are used to make the Yukawa operators diagonal (i.e. to stick a particular flavon \(\phi_{D_i}^c\) to a particular matter field \(D_i^c\)). The \(Z_3^{D}\) is used to control the down messenger sector of the model leading to the diagrams in figure 2.

The \(Z_3\) allowed effective operators, which result from the diagrams in figure 2 below the scales \(\langle \Sigma \rangle\) and \(\langle \Sigma_D \rangle\) (which are assumed to be higher than the \(A_4\) breaking scale) are

\[
\frac{y_d^2}{\langle \Sigma \rangle} h_d(\phi_{D_i}, Q)D_i^c + \frac{y_s^2}{\langle \Sigma \rangle} h_d(\phi_{D_2}, Q)D_2^c + \frac{y_b^2}{\langle \Sigma \rangle} h_d(\phi_{D_3}, Q)D_3^c,
\]

where we have introduced a new PS Higgs in the adjoint of SU(4)\(_{PS}\), \(h_D \sim (15, 2, -1/2)\), which couples to \(D_3^c\), leading a Clebsch factor of 3 between charged lepton and down-type quark masses for the second family \([30]\). The messenger mass for the first family arises from the coupling to an adjoint of SU(4)\(_{PS}\), \(\Sigma_D \sim (15, 1, 0)\), giving a Clebsch factor of 3 in the denominator \([32]\). The messenger mass for the second and third families arises from the PS singlet \(\Sigma \sim (1, 1, 0)\) so no inverse Clebsch factors arise in these cases.

The resulting Yukawa matrices are diagonal and given by,

\[
Y^d = \begin{pmatrix}
y_d & 0 & 0 \\
0 & y_s & 0 \\
0 & 0 & y_b
\end{pmatrix}, \quad Y^e = \begin{pmatrix}
y_d/3 & 0 & 0 \\
0 & 3y_s & 0 \\
0 & 0 & y_b
\end{pmatrix},
\]
Figure 2. These diagrams show the messenger sector responsible for the effective operators in eq. (2.9) responsible for the charged lepton and down quark masses.

Table 2. Fields which transform under the $Z_3$ symmetries which control the down sector (where $\omega = e^{i2\pi/3}$). Fields not shown in this table (for example $h_d$) are singlets under all $Z_3$ symmetries.

\[
\begin{array}{cccccccccccc}
\text{Field} & h_D & D_1^c & D_2^c & D_3^c & \phi_D & \phi_D^c & \phi_D^c & \Sigma & \Sigma_{15} & X_{Q_1} & X_{Q_1} & X_{Q_2} & X_{Q_2} & X_{Q_3} & X_{Q_3} \\
Z_3^D & \omega^2 & \omega & \omega^2 & 1 & 1 & \omega & \omega^2 & \omega^2 & \omega^2 & \omega & 1 \\
Z_3^D & 1 & \omega^2 & 1 & 1 & \omega & 1 & 1 & 1 & 1 & 1 & 1 \\
Z_3^D & 1 & 1 & \omega^2 & 1 & 1 & \omega & 1 & 1 & 1 & 1 & 1 \\
Z_3^D & 1 & 1 & 1 & \omega^2 & 1 & 1 & \omega & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
\end{array}
\]

where

\[
y_d = \frac{y_{D1}^D v_{D_1}}{\langle \Sigma_{15} \rangle}, \quad y_s = \frac{y_{D2}^D v_{D_2} \epsilon \phi_{D_2}}{\langle \Sigma \rangle}, \quad y_b = \frac{y_{D3}^D v_{D_3}}{\langle \Sigma \rangle},
\]

(2.11)

where we have included a small mixing parameter $\epsilon_D$,\(^1\) associated with the high energy mixing of the Higgs doublet arising from $h_D \sim (15, 2, -1/2)$ with that in $h_d \sim (1, 2, -1/2)$, which may account for the smallness of the second family masses. The down-type quark and charged lepton masses are then given by,

\[
m_e = \frac{m_d}{3}, \quad m_\mu = 3m_s, \quad m_\tau = m_b.
\]

These are the well-known Georgi-Jarlskog (GJ) relations [30], although here they arise from a new mechanism, namely due to non-singlet fields which appear in the denominator of effective operators and split the messenger masses [32]. The viability of the GJ relations is discussed in [33]. The smallness of the down quark mass compared to the bottom quark mass is ascribed to the different couplings and VEVs involved in the ratio $y_d/y_b$, for example by assuming a small ratio $\langle \Sigma \rangle/\langle \Sigma_{15} \rangle \ll 1$.

2.4 The up sector

We now turn to the up sector where the $Z_5$ symmetries are shown in table 3. The $Z_5^{\ell \epsilon}$ are used to make the Yukawa operators diagonal (i.e. to stick a particular flavon $\phi_{U \ell}$ to a

\(^{1}\)The smallness of the parameter $\epsilon_D$ may be naturally explained since this mixing arises from non-renormalisable operators as discussed earlier.
Figure 3. This diagram shows the messenger sector responsible for the effective operator in eq. (2.13) responsible for the top quark mass and third family Dirac neutrino mass.

Table 3. Fields which transform under the $Z_5$ symmetries which control the up sector (where $\rho = e^{2\pi i/5}$). Fields not shown in this table (for example $Q$) are singlets under all $Z_5$ symmetries.

particular matter field $U_i^c$). The $Z_5^{\theta_U}$ is used to generate the pronounced mass hierarchy in the up sector, via powers of the flavon field $\theta_U$, which is a singlet of both $A_4$ and the Pati-Salam group. Since the messenger sector in the up sector is more cumbersome than that in the down sector, involving the additional flavons $\theta_U$, we only show the operator responsible for the top quark and third family neutrino Yukawa coupling in figure 3. We highlight an important feature of the messenger sector, namely the presence of a symmetry $Z_5^U$ which ensures that the third family involves a messenger mass term arising from $\langle \Sigma_{15}' \rangle$, while the first two families involve messenger masses proportional to $\langle \Sigma' \rangle$. This implies that the Dirac mass of the third family neutrino is $1/3$ that of the top quark, leading to a normal neutrino mass hierarchy, as we discuss later.

The leading order $Z_5$ allowed effective operators are,

$$
\frac{y_U^1}{\langle \Sigma \rangle} \frac{\theta_U^2}{\Lambda^2} h_u(\phi_U e_i^c, Q) U_i^c + \frac{y_U^2}{\langle \Sigma \rangle} \frac{\theta_U}{\Lambda} h_u(\phi_U e_i^c, Q) U_i^c + \frac{y_U^2}{\langle \Sigma_{15}' \rangle} h_u(\phi_U e_i^c, Q) U_i^c.
$$

(2.13)

For example, below the PS and $Z_5^{\theta_U}$ and $Z_5^U$ breaking scales, the operators relevant for the

\footnote{With an alternative choice of charges some of these operators may involve the Higgs $h_u \sim (15, 2, 1/2)$ leading to Clebsch Gordan coefficients analogous to those appearing in the down sector. For example if $U_i^c$ is assigned a $Z_5^U$ charge of $\rho^i$, with all other charges unchanged, then the second operator in eq. (2.13) will involve $h_u$ instead of $h_u$, leading to a Clebsch Gordan coefficient of $3$ multiplying the second column of the neutrino Yukawa matrix $Y^\nu$ in eq. (2.15), and hence $m_D^{\nu_2} = 3m_e$.}
neutrino Yukawa matrix $Y^\nu$, emerging from eq. (2.13), can be written in a more suggestive notation as,

$$
y_{1\nu} \frac{\langle \Sigma' \rangle}{\langle \Sigma \rangle} e^2 h_u(\phi_{atm} \cdot L) N_{atm}^c + y_{2\nu} \frac{\langle \Sigma' \rangle}{\langle \Sigma \rangle} e h_u(\phi_{sol} \cdot L) N_{sol}^c + y_{3\nu} \frac{\langle \Sigma' \rangle_{15}}{\langle \Sigma_{15} \rangle} h_u(\phi_{dec} \cdot L) N_{dec}^c,
$$

(2.14)

where we have written $\phi_{atm} \equiv \phi U_3 \phi_{sol} \equiv \phi U_2 \phi_{dec} \equiv \phi U_1$ and $\epsilon = \frac{\langle \theta_U \rangle}{\Lambda}$. Since these triplet flavons acquire real VEVs these operators will result in a real neutrino Yukawa matrix.

With the vacuum alignments in eq. (2.5), the operators in eq. (2.13) therefore result in the Yukawa matrices,

$$Y^u = \begin{pmatrix} 0 & b \epsilon & 0 \\ a \epsilon^2 & 4b \epsilon & 0 \\ a \epsilon^2 & 2b \epsilon & c \end{pmatrix}, \quad Y^\nu = \begin{pmatrix} 0 & b \epsilon & 0 \\ a \epsilon^2 & 4b \epsilon & 0 \\ a \epsilon^2 & 2b \epsilon & c/3 \end{pmatrix},$$

(2.15)

where

$$a = \frac{y_{1\nu} \epsilon U_1}{\sqrt{2} \langle \Sigma' \rangle}, \quad b = \frac{y_{2\nu} \epsilon U_2}{\sqrt{2} \langle \Sigma' \rangle}, \quad c = \frac{y_{3\nu} \epsilon U_3}{\langle \Sigma_{15} \rangle}.$$

(2.16)

Note that the large top mass implies,

$$c = \frac{y_{3\nu} \epsilon U_3}{\langle \Sigma_{15} \rangle} \sim 1.$$

(2.17)

This implies that $\langle \phi_{U_3} \rangle \sim \langle \Sigma'_{15} \rangle$ and hence the messenger mass in figure 3 is of the same order as the flavon VEV.

The hierarchy of up-type quark masses is controlled by the small parameter $\epsilon$, and assuming $a \sim b \sim c$, we expect

$$m_u : m_c : m_t \sim \epsilon^2 : \epsilon : 1,$$

(2.18)

where we assume,

$$\epsilon = \frac{\langle \theta_U \rangle}{\Lambda} \sim 10^{-3}.$$

(2.19)

2.5 The Majorana sector

In the Majorana sector the $Z_5$ allowed leading operators are diagonal and given by,

$$y_1 \xi_1 \frac{\theta_U}{\Lambda} \bar{H}_L \bar{H}_L U_1^c U_1^c + y_2 \xi_2 \frac{\theta_U}{\Lambda} \bar{H}_L \bar{H}_L U_2^c U_2^c + y_3 \xi_3 \frac{\bar{H}_L \bar{H}_L U_3^c U_3^c}{\Lambda},$$

(2.20)

where $\xi_j$ are three singlets under both $A_4$ and the Pati-Salam group. The operators relevant for the heavy Majorana mass matrix $M_R$, emerging from eq. (2.20), can be written in a more suggestive notation as,

$$y_{1\nu} \epsilon^4 \xi_{atm} N_{atm}^c \nu_{atm}^c + y_{2\nu} \epsilon^2 \xi_{sol} N_{sol}^c \nu_{sol}^c + y_{3\nu} \epsilon \xi_{dec} N_{dec}^c \nu_{dec}^c,$$

(2.21)
where we have written $\xi_{\text{atm}} \equiv \xi_1$, $\xi_{\text{sol}} \equiv \xi_2$, $\xi_{\text{dec}} \equiv \xi_3$ and $y'_i = y_i \frac{(\tan\beta)^2}{\Lambda_h}$, leading to a diagonal right-handed neutrino mass matrix,

$$M_R = \begin{pmatrix} e^4 \tilde{M}_1 & 0 & 0 \\ 0 & e^2 \tilde{M}_2 & 0 \\ 0 & 0 & \tilde{M}_3 \end{pmatrix},$$

(2.22)

where,

$$\tilde{M}_1 = y'_1 \langle \xi_{\text{atm}} \rangle, \quad \tilde{M}_2 = y'_2 \langle \xi_{\text{sol}} \rangle, \quad \tilde{M}_3 = y'_3 \langle \xi_{\text{dec}} \rangle.$$

(2.23)

Assuming roughly equal VEVs for $\xi_i$ we expect $\tilde{M}_1 \sim \tilde{M}_2 \sim \tilde{M}_3$ and hence a very strong hierarchy of right-handed neutrino masses, being roughly proportional to the squares of up-type quark masses in eq. (2.18), hence given by the order of magnitude ratios $10^{-12} : 10^{-6} : 1$. According to eq. (2.15) the model equates up-type quark masses with Dirac neutrino masses, apart from the Clebsch factor of 1/3 for the third family.\footnote{Alternatively with a Clebsch factor of 3 in the second column, as discussed in the previous footnote, we could have $m_{D\nu}^2 = 3m_c$.}

$$m_{D\nu}^1 = m_u, \quad m_{D\nu}^2 = m_c, \quad m_{D\nu}^3 = \frac{m_t}{3}.$$  

(2.24)

The discrete charges (and hence powers of $\theta_U$ and $e$) cancel in the see-saw mechanism. This cancellation is natural, being controlled by the $Z_5$ family symmetry, leading to the physical neutrino masses being not very hierarchical, apart from $m_1$ which is suppressed by a factor of 9. The model therefore predicts a normal mass hierarchy, $m_1 \ll m_2 < m_3$ corresponding to

$$\frac{(m_{D\nu}^3)^2}{M_3} \ll \frac{(m_{D\nu}^2)^2}{M_2} \ll \frac{(m_{D\nu}^1)^2}{M_1}.$$  

(2.25)

For example, $m_1 \sim (m_{D\nu}^3)^2/M_3 \sim m_t^2/(9M_3) \sim 0.3$ meV requires $M_3 \sim 10^{16}$ GeV and hence $M_1 \sim 10$ TeV, $M_2 \sim 10^{10}$ GeV. The lightest right-handed neutrino will be difficult to observe at colliders, due to its high mass and small Yukawa coupling of about $10^{-6}$. It is cosmologically unstable, decaying promptly into a neutrino plus Higgs. Note that we identify $m_1 \equiv m_{\text{dec}}, m_2 \equiv m_{\text{sol}}, m_3 \equiv m_{\text{atm}}$ and hence the heaviest right-handed neutrino of mass $M_3$ (from the top quark multiplet) is identified as the decoupled one $N_{\text{dec}}$. The intermediate one of mass $M_2$ (from the charm quark multiplet) is denoted as $N_{\text{sol}}$, since it is responsible for the solar neutrino mass. The lightest right-handed neutrino of mass $M_1$ (from the up quark multiplet) is denoted as $N_{\text{atm}}$ since it is responsible for the atmospheric neutrino mass. These identifications, familiar from SD [14–18], were depicted in figure 1.

3 Leading order results

3.1 Overview

It is convenient to collect in one place all the lowest order quark and lepton Yukawa matrices (in LR convention) and heavy Majorana mass matrix $M_R$ which are predicted by the model

\[...\]
just below the high energy Pati-Salam breaking scale $\sim \text{few } \times 10^{16} \text{ GeV}$,

$$Y^d = \begin{pmatrix} y_d & 0 & 0 \\ 0 & y_s & 0 \\ 0 & 0 & y_b \end{pmatrix}, \quad Y^e = \begin{pmatrix} y_d/3 & 0 & 0 \\ 0 & 3y_s & 0 \\ 0 & 0 & y_b \end{pmatrix},$$

$$Y^u = \begin{pmatrix} 0 & be & 0 \\ ae^2 & 4be & 0 \\ ae^2 & 2be & c \end{pmatrix}, \quad Y^\nu = \begin{pmatrix} 0 & be & 0 \\ ae^2 & 4be & 0 \\ ae^2 & 2be & c/3 \end{pmatrix}, \quad M_R = \begin{pmatrix} \epsilon^4 \tilde{M}_1 & 0 & 0 \\ 0 & \epsilon^2 \tilde{M}_2 & 0 \\ 0 & 0 & \tilde{M}_3 \end{pmatrix}$$

(3.1)

where we assume the phenomenologically required values of $y_d, y_s, y_b$ and we fix $\epsilon = 10^{-3}$, which implies that the remaining parameters take natural values,

$$a \sim b \sim c \sim 1, \quad \tilde{M}_1 \sim \tilde{M}_2 \sim \tilde{M}_3 \sim 10^{16} \text{ GeV},$$

(3.3)

where we allow these parameters to differ from each other by up to an order of magnitude.

The main results follow directly from the simple forms of matrices above:

- $m_e = m_3$, $m_\mu = 3m_s$, $m_\tau = m_b$ ($y_d, y_s, y_b$ chosen to fit the down quark masses)
- $m^{D}_{\nu 1} = m_u = |a|v_u^2/\sqrt{17}$, $m^{D}_{\nu 2} = m_e = \sqrt{17}|b|v_u\epsilon$, $m^{D}_{\nu 3} = m_t/3 = |c|v_u/3$
- $M_1 : M_2 : M_3 \sim m_u^2 : m_e^2 : m_t^2$ (RH neutrino masses are very hierarchical)
- For example, $M_1 \sim 10 \text{ TeV}$, $M_2 \sim 10^{10} \text{ GeV}$, $M_3 \sim 10^{16} \text{ GeV}$
- The model predicts a normal neutrino hierarchy, due to the Clebsch suppression factor of 1/3 in the neutrino Yukawa mass which implies $(m^{D}_{\nu 3})^2 \ll (m^{D}_{\nu 2})^2, (m^{D}_{\nu 1})^2$.
- For example, $m_1 \sim 0.3 \text{ meV}$, $m_2 \sim 8.5 \text{ meV}$, $m_3 \sim 50 \text{ meV}$ (normal hierarchy)
- $Y^\nu \sim Y^u$ is the only non-diagonal matrix is responsible for all quark and lepton mixing, which is fully specified once $a, b, c$ are fixed by up quark masses
- Lepton mixing angles and CP violation are predicted for the phenomenological range of $m_2/m_3$, assuming a relative phase of $2\pi/5$ between the first and second columns.
- The Cabibbo angle is predicted to be $\theta_C \approx 1/4$ or $\theta_C \approx 14^\circ$ at leading order
- The other quark mixing angles and CP violating phase are zero at leading order

The first set of relations (which are valid at the Pati-Salam breaking scale) are just the usual Georgi-Jarlskog (GJ) relations from SU(5) [30]. The tetra-model also yields an SO(10)-like pattern of Dirac and heavy Majorana neutrino masses widely studied in the literature [34–36]. However the light physical Majorana neutrino masses are not so hierarchical since the powers of $\epsilon$ cancel in the see-saw mechanism. It has recently been shown that the serious difficulties facing thermal leptogenesis in SO(10)-like models may be circumvented when the production from the next-to-lightest right-handed neutrinos and flavour effects are properly taken into account [37, 38], so the prospects for thermal leptogenesis in the tetra-model look promising. Note that if we were to have $m^{D}_{\nu 2} = 3m_e$, as is
possible in the alternative model discussed in the previous footnotes, then this would increase $M_2$ by a factor of 9, enhancing the leptogenesis asymmetry from the next-to-lightest right-handed neutrino. Finally, it is noteworthy that the Cabibbo angle is successfully predicted at leading order (to within one degree) as a consequence of the vacuum alignment and quark-lepton unification, providing the Cabibbo connection between quark and lepton mixing. This is one of the main successes of the model, being a consequence of the $(1, 4, 2)$ vacuum alignment which also successfully reproduces lepton mixing, as we now discuss.

3.2 Leading order lepton mixing

In this subsection we discuss the leading order predictions for PMNS mixing which arise from the vacuum alignment.

The physical effective neutrino Majorana mass matrix $m^\nu$ is determined from the columns of $Y^\nu$ via the see-saw mechanism,

$$m^\nu = -v^2_u Y^\nu M^{-1}_R Y^{\nu T},$$  

(3.4)

where the Majorana neutrino mass matrix $m^\nu$, defined by

$$\mathcal{L}_\nu = -\frac{1}{2} m^\nu \bar{\nu}_L \nu^c_L + \text{h.c.},$$

is diagonalised by

$$U_{\nu_L} m^\nu U_{\nu_L}^T = \begin{pmatrix} m_1 & 0 & 0 \\ 0 & m_2 & 0 \\ 0 & 0 & m_3 \end{pmatrix}.$$  

(3.5)

The PMNS matrix is then given by

$$U_{\text{PMNS}} = U_{\nu_L} U_{\nu_L}^\dagger.$$  

(3.6)

We use a standard parameterization $U_{\text{PMNS}} = R^d_{23} U_{13}^l R^l_{12} P^l$, in terms of $s^l_{ij} = \sin(\theta^l_{ij})$, $c^l_{ij} = \cos(\theta^l_{ij})$, the Dirac CP violating phase $\delta^l$ and further Majorana phases contained in $P^l = \text{diag}(e^{i\beta^l_1}, e^{i\beta^l_2}, 1)$. The standard PDG parameterization [40] differs slightly due to the definition of Majorana phases which are by given by $P^l_{\text{PDG}} = \text{diag}(1, e^{i\alpha^l_{21}}, e^{i\alpha^l_{31}})$. Evidently the PDG Majorana phases are related to those in our convention by $\alpha^l_{21} = \beta^l_2 - \beta^l_1$ and $\alpha^l_{31} = -\beta^l_1$, after an overall unphysical phase is absorbed by $U_{\nu_L}$.

Using the see-saw formula in eq. (3.4), with the neutrino Yukawa matrix $Y^\nu$ in eq. (2.15) and the right-handed Majorana mass matrix $M_R$ in eq. (2.22), we find the neutrino mass matrix $m^\nu$, up to an overall irrelevant phase which may be taken to be real, can be written as

$$m^\nu = m_a \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & 1 \end{pmatrix} + m_b e^{2i\eta} \begin{pmatrix} 1 & 4 & 2 \\ 4 & 16 & 8 \\ 2 & 8 & 4 \end{pmatrix} + m_c \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$  

(3.7)

where $m_a = |a|^2 v^2_u/|\tilde{M}_1|$, $m_b = |b|^2 v^2_u/|\tilde{M}_2|$, $m_c = |c|^2 v^2_u/(9|\tilde{M}_3|)$ are real parameter combinations which determine the three physical neutrino masses $m_3, m_2, m_1$, respectively. Note

\footnote{Note that this convention for the light effective Majorana neutrino mass matrix $m^\nu$ differs by an overall complex conjugation compared to that used in the Mixing Parameter Tools package [39].}
that $m_1$ is suppressed by a factor of 9 compared to the other neutrino masses due to the Clebsch-Gordan factor of 1/3 in the third family Dirac neutrino mass. We written the relative phase difference between the first two two terms as $2\eta$. As shown recently [12], fixing $\eta = \pm 2\pi/5$, using the phases of the singlet flavon VEVs $\langle \xi \rangle$, then determines all the lepton mixing angles and phases in terms of the ratio $\epsilon = m_\nu/m_\alpha$. Changing the sign of the phase $\eta = \pm 2\pi/5$ leaves the predictions for the angles unchanged, but reverses the signs of the Dirac and Majorana phases [13]. Here we shall select $\eta = 2\pi/5$ since it leads to a negative Dirac phase, preferred by the most recent global fits [3]. Since $\eta$ is crucial to the predictions in the lepton sector, it is worthwhile discussing the origin of this phase in more detail.

In order to understand the origin of phases which enter the neutrino mass matrix $m^\nu$, it is worth recalling that the operators responsible for the neutrino Yukawa and Majorana masses are those given in eqs. (2.14) and (2.21). Implementing the see-saw mechanism, the effective neutrino mass matrix $m^\nu$ in eq. (3.7) emerges from the flavon combinations,

$$m^\nu \sim \frac{\langle \phi_{\text{atm}} \rangle \langle \phi_{\text{atm}} \rangle^T}{\langle \xi_{\text{atm}} \rangle} + \frac{\langle \phi_{\text{sol}} \rangle \langle \phi_{\text{sol}} \rangle^T}{\langle \xi_{\text{sol}} \rangle} + \frac{\langle \phi_{\text{dec}} \rangle \langle \phi_{\text{dec}} \rangle^T}{\langle \xi_{\text{dec}} \rangle}. \tag{3.8}$$

Notice that the powers of $\epsilon$ cancel in the see-saw mechanism, leading to a rather mild hierarchy in the neutrino sector. Since we are assuming that the original theory respects CP, the only source of phases can be the VEVs of flavons. The phase $\eta = 2\pi/5$ then must arise from the difference between flavon VEVs. The phases of flavon VEVs arise in the context of spontaneous CP violation from discrete symmetries as discussed in [42, 43], and we shall follow the strategy outlined there. The basic idea is to impose CP conservation on the theory so that all couplings and masses are real. Note that the $A_4$ assignments in table 1 do not involve the complex singlets $1', 1''$ or any complex Clebsch-Gordan coefficients so that the definition of CP is straightforward in this model and hence all the different ways that CP may be defined in $A_4$ [44–48] are equivalent for our purposes (see [42, 43] for a discussion of this point). The CP symmetry is broken in a discrete way by the form of the superpotential terms.

We have already stated that the flavon VEVs $\langle \phi_{\text{atm}} \rangle$ and $\langle \phi_{\text{sol}} \rangle$ are real and in this case the phase $\eta$ must arise from the singlet flavons VEVs $\langle \xi_i \rangle$. For example, eq. (3.8) shows that the phase $\eta$ in eq. (3.7) could originate from the solar flavon VEV $\langle \xi_{\text{sol}} \rangle \sim e^{-i4\pi/5}$, if the atmospheric flavon vev $\langle \xi_{\text{atm}} \rangle$ is real and positive. This can be arranged if the right-handed neutrino flavon vevs arise from $Z_5$ invariant quintic terms in the superpotential,

$$g_1P_1 \left( \frac{\xi_{\text{atm}}}{A_4^5} - \mu_1^2 \right) + g_2P_2 \left( \frac{\xi_{\text{sol}}}{A_2^5} - \mu_2^2 \right) + g_3P_3 \left( \frac{\xi_{\text{dec}}}{A_3^5} - \mu_3^2 \right), \tag{3.9}$$

where, as in [42, 43], the driving singlet fields $P_i$ denote linear combinations of identical singlets and all couplings and masses are real due to CP conservation. The F-term conditions from eq. (3.9) are,

$$\left| \frac{\langle \xi_{\text{atm}} \rangle}{A_4^5} - \mu_1^2 \right|^2 = \left| \frac{\langle \xi_{\text{sol}} \rangle}{A_2^5} - \mu_2^2 \right|^2 = \left| \frac{\langle \xi_{\text{dec}} \rangle}{A_3^5} - \mu_3^2 \right|^2 = 0. \tag{3.10}$$
These are satisfied, for example, by $\langle \xi_{\text{atm}} \rangle = |(A_1^3 m_1^2)^{1/5}|$ and $\langle \xi_{\text{sol}} \rangle = |(A_2^3 m_2^2)^{1/5}| e^{4\pi i/5}$ and $\langle \xi_{\text{dec}} \rangle = |(A_3^2 m_3^2)^{1/5}|$ where we arbitrarily select two of the phases to be zero and the solar phase to be $-4\pi/5$ from amongst a discrete set of possible choices in each case. More generally we select a phase difference of $-4\pi/5$ between $\langle \xi_{\text{atm}} \rangle$ and $\langle \xi_{\text{sol}} \rangle$, with an arbitrary phase for $\langle \xi_{\text{dec}} \rangle$, since the overall phase is not physically relevant and the decoupled phase is not important, which would happen one in five times by chance. In the basis where the right-handed neutrino masses are real and positive this is equivalent to having a phase $\eta = 2\pi/5$ in eq. (3.7).

Returning to eq. (3.7), with $\eta = 2\pi/5$, the six predictions vary with $\epsilon_\nu$, or equivalently $m_2/m_3$, as shown in table 4 for a fixed value of $m_1 = 0.3$ meV. It is remarkable that, for the physical range of $m_2/m_3$, the PMNS lepton mixing angles are predicted to be $\theta_{12}^l \approx 34^\circ$, $\theta_{23}^l \approx 40^\circ$ and $\theta_{13}^l \approx 9^\circ$, which agree with the current best fit values for a normal neutrino mass hierarchy, together with the CP violating oscillation phase $\delta^l \approx 260^\circ$ and Majorana phases $\beta_1^l \approx 322^\circ$ and $\beta_2^l \approx 75^\circ$ corresponding to the PDG Majorana phases $\alpha_{21} \approx 113^\circ$ and $\alpha_{31} \approx 38^\circ$.\(^5\) We emphasise that the tetra-model predicts both a normal hierarchy and an atmospheric angle in the first octant. Both these predictions will be subjected to experimental scrutiny in the near future [49–52].

| $\epsilon_\nu$ | $m_2/m_3$ | $\theta_{12}^l$ | $\theta_{13}^l$ | $\theta_{23}^l$ | $\delta^l$ | $\beta_1^l$ | $\beta_2^l$ | $\alpha_{21}$ | $\alpha_{31}$ |
|---------------|-------------|----------------|----------------|----------------|----------|-------------|-------------|---------------|---------------|
| 0.057         | 0.166       | 34.3°          | 8.75°          | 39.6°          | 258°     | 323°        | 77.5°       | 114°          | 37°           |
| 0.058         | 0.170       | 34.2°          | 8.9°           | 39.7°          | 259°     | 322°        | 76°         | 114°          | 37.5°         |
| 0.059         | 0.174       | 34.1°          | 9.1°           | 39.8°          | 260°     | 322°        | 75°         | 113°          | 38°           |
| 0.060         | 0.178       | 34.0°          | 9.3°           | 39.9°          | 260°.5   | 321°        | 73°         | 112°          | 39°           |
| 0.061         | 0.182       | 33.9°          | 9.4°           | 40.0°          | 261°     | 320°        | 72°         | 112°          | 40°           |

Table 4. The leading order predictions for PMNS parameters as a function of $\epsilon_\nu = m_3/m_2$ and hence $m_2/m_3$, for $m_1 = 0.3$ meV and $m_2 = 50$ meV. Note that these predictions assume $\eta = 2\pi/5$. The predictions are obtained numerically using the Mixing Parameter Tools (MPT) package based on [39], taking into account the different conventions. The last two columns also show the PDG Majorana phases [40] given by $\alpha_{21} = \beta_2^l - \beta_1^l$ and $\alpha_{31} = -\beta_1^l$.

\(^5\)If we were to set $m_1 = 0$ and choose the opposite phase $\eta = -2\pi/5$ then we would find the results presented previously in [12], namely $\theta_{12}^l \approx 34^\circ$, $\theta_{23}^l \approx 41^\circ$, $\theta_{13}^l \approx 9.5^\circ$, $\delta^l \approx 106^\circ$. Note that the presence of the non-zero mass $m_1 = 0.3$ meV reduces the reactor angle by about half a degree, bringing it even closer to the central value observed by Daya Bay of $\theta_{13}^l \approx 8.7^\circ$ [5]. Such $m_1$ corrections to SD were first considered in [41].
4 Higher order corrections

4.1 Higher order operators

Since the vacuum alignments are achieved by a renormalisable superpotential, it is possible that the HO corrections to vacuum alignment, originating from non-renormalisable operators, are highly suppressed compared to the LO alignments. We are free to assume this, since the messenger scale associated with such HO operators is unconstrained by the model. Therefore we shall ignore the corrections to vacuum alignment in our analysis.

The HO operators in the down Yukawa sector arise from cubic insertions flavon fields \( \phi^3_{Dc} \) which are singlets under the \( Z_3 \) symmetries. These insertions are accompanied by messenger mass suppressions \( \langle \Sigma \rangle^3 \) or \( \langle \Sigma_{15} \rangle^3 \) which are also \( Z_3 \) singlets. The flavons \( \phi^3_{Dc} \) may lead to significant suppression since the factor \( \langle \phi^3_{Dc} \rangle / \langle \Sigma \rangle \) is responsible for the bottom quark Yukawa coupling, and the other flavons are responsible for the strange and down quark masses and so their contribution will be highly suppressed. Therefore the dominant HO correction arises from insertions of \( \phi^3_{Dc} \) corresponding to a suppression of order \( y_3^3 \). The most important HO operators in the down sector arising are then, dropping the coupling constants and scales,

\[
h_d(\phi^3_{Dc} \phi_{Dc}^3 Q) D^c_1 + h_D(\phi^3_{Dc} \phi_{Dc}^3 Q) D^c_2 + h_d(\phi^3_{Dc} \phi_{Dc}^3 Q) D^c_3,
\]

(4.1)

The \( A_4 \) contractions in the above HO operators differ from the LO contractions previously. In particular an \( A_4 \) singlet is achieved by contracting \( A_4 \) triplets inside the round brackets in eq. (4.1) in all possible ways. We find that the allowed contractions from the above operators result in dominant corrections to the down Yukawa matrix of the form,

\[
Y^d = \begin{pmatrix}
y_d & O(y_s y_3^3) & 0 \\
O(y_d y_3^3) & y_s & 0 \\
0 & 0 & y_b
\end{pmatrix},
\]

(4.2)

The corrections are negligible providing \( \tan \beta \) is not too large. For example, for \( \tan \beta \lesssim 10 \), we have \( y_b \lesssim 0.1 \) and hence \( y_b^3 \lesssim 10^{-3} \), resulting in a very small and negligible contribution to the Cabibbo angle.

The HO operators in the up Yukawa sector arise from quintic insertions of flavon fields \( \phi^5_{Uc} \). These insertions are accompanied by messenger mass suppressions \( \langle \Sigma' \rangle^5 \) or \( \langle \Sigma'_{15} \rangle^5 \) which are also \( Z_5 \) singlets. The flavons \( \phi_{Uc} \) should not lead to too much suppression since the factor \( \langle \phi_{Uc} \rangle / \langle \Sigma'_{15} \rangle \) is responsible for the top quark Yukawa coupling, and the other flavons are assumed to have similar VEVs (with the hierarchy in the up sector generated by powers of \( \epsilon \) associated with powers of the \( \theta_U \) VEV). For example if we were to assume that each insertion of flavon field were associated with a mild suppression factor of \( 1/2 \) then the quintic insertions would correspond to a suppression of \( 1/2^5 \sim 1/30 \). Such corrections may dominate over those coming from the down sector, at least for low or moderate \( \tan \beta \), and here we assume that they provide the most important corrections to quark mixing.

The operator insertions \( \phi_{Uc} \xi^2_{ij} \) are also singlets and should be included. We shall assume that they are competitive with the previous operators, although the messenger masses
associated with these operators is not determined. The most important HO operators in
the up sector arising from the insertions of the above operators are then, dropping the
coupling constants and scales,

\[ \sum_{j=1}^{3} h_u \theta_u^2 (\phi^U_{j} \phi Q) U_1^c + h_u \theta_u (\phi^U_{j} \phi^U_{2} Q) U_2^c + h_u (\phi^U_{j} \phi^U_{3} Q) U_3^c \]

where we assume that each of these operators will lead to a correction compared to the
corresponding LO operator with an extra suppression factor of order $\sim 1/30$ according
to the above example. Note that these HO operators respect the hierarchy generated
by powers of $\epsilon$ associated with powers of the $\theta_U$ VEV, so do not disturb the up type
quark mass hierarchy. The $A_4$ contractions in the above HO operators differ from the LO
contractions previously. In particular an $A_4$ singlet is achieved by contracting $A_4$ triplets
inside the round brackets in eq. (4.3) in all possible ways. In this case, due to the pattern
of alignments in eq. (2.5), and the fact that all operator insertions contribute equally, we
expect a large number of allowed contractions, with similar multiplicative corrections filling
all entries of the up and neutrino Yukawa matrices. However the corrections involving $Q_1$
(i.e. the correction in the first row of the up Yukawa matrix) may be smaller by a factor of
1/4 due to the alignments in eq. (2.5). We shall discuss the phenomenological impact of
these corrections later.

In the Majorana sector the above charge assignments allow higher order mixed terms
such as

\[ \frac{1}{\Lambda^3(\Sigma)} \frac{1}{\Lambda_R^2} \theta_u^3 (\phi^U_{j} \phi^U_{2}) \bar{H}_u \bar{H}_u \bar{U}_1^c \bar{U}_2^c, \]

leading to an off-diagonal right-handed neutrino mass matrix,

\[ M_R = \begin{pmatrix} \epsilon^4 \tilde{M}_1 & \epsilon^3 \tilde{M}_{12} & 0 \\ \epsilon^3 \tilde{M}_{12} & \epsilon^2 \tilde{M}_2 & 0 \\ 0 & 0 & \tilde{M}_3 \end{pmatrix}, \]

where,

\[ \tilde{M}_{12} = y_{12} \frac{\nu_{U_{1}} \nu_{U_{2}}}{(\Sigma)} \frac{(\bar{H}_{N}^c)^2}{\Lambda_R^2}. \]

This operator contributes off-diagonal terms to the right-handed neutrino mass matrix of a
magnitude which depends on the absolute scale of the flavon vevs $\langle \phi^U_{j} \rangle$ and $\langle \phi^U_{2} \rangle$ compared
to $\langle \xi_{1} \rangle$ and $\langle \xi_{2} \rangle$. If all flavon vevs and messenger scales in the neutrino sector are set equal
then we would expect $\tilde{M}_{12} \sim \tilde{M}_1$, with a significant contribution to atmospheric mixing
even if $\epsilon \sim 10^{-3}$ due to the hierarchical nature of the neutrino Yukawa matrix. However this
correction may be completely insignificant if $\langle \phi^U_{j} \rangle \ll \langle \xi_{i} \rangle$ which would imply $\tilde{M}_{12} \ll \tilde{M}_1$.

Since we require \( \langle \xi_{i} \rangle \sim 10^{16} \text{ GeV} \), in order to obtain a small enough value of $m_1$, this is
tantamount to assuming that $\langle \phi^U_{j} \rangle \ll 10^{16} \text{ GeV}$.
4.2 The up quark and neutrino Yukawa matrix at higher order

As discussed in the previous subsection, the down and charged lepton Yukawa matrices receive negligible HO corrections and may be neglected to good approximation. We therefore assume that the down quark Yukawa matrix is unchanged from its diagonal form given earlier in eq. (2.10). On the other hand, the up quark and neutrino Yukawa matrices are expected to be corrected by a complicated set of operators and contractions as shown in eq. (4.3), with the corrections being of order $\sim \mathcal{O}(1/30)$. This implies that CKM mixing originates entirely from the up quark Yukawa matrix which takes the general form, in the presence of (complex) HO corrections,

$$
\begin{pmatrix}
\epsilon_{11} c^2 & b c (1 + \epsilon_{12}) & \epsilon_{13} c \\
ac^2 (1 + \epsilon_{21}) & 4 b c (1 + \epsilon_{22}) & \epsilon_{23} c \\
ac^2 (1 + \epsilon_{31}) & 2 b c (1 + \epsilon_{32}) & c (1 + \epsilon_{33})
\end{pmatrix},
$$  \hspace{1cm} (4.7)

with a similar matrix for the neutrino Yukawa matrix, differing only by Clebsch factors.

Each of the parameters $\epsilon_{ij}$ may in general receive contributions from several operator contractions arising from eq. (4.3), each with a quantised phase (a fifth root of unity) and each entering with an arbitrary coefficient. The parameters $\epsilon_{ij}$ are therefore taken to be arbitrary complex parameters, with modulus $\leq \mathcal{O}(1/30)$, which correct the leading order mixing predictions in both the lepton and quark sectors. In the limit $\epsilon_{ij} = 0$ the matrices reduce to the simple forms in eq. (3.2). Before discussing the effect of the higher order corrections in detail, it is useful to begin with an overview of the significance of the three columns of this matrix for lepton and quark mixing as follows:

- The first column of eq. (4.7) is mainly responsible for the atmospheric neutrino mass and mixing. The reactor angle and leptonic CP violation originates from the interplay between the first and second columns, being sensitive to the relative phase between these two columns. The first column is irrelevant to CKM to good approximation, being suppressed by $c^2$ which is related to the smallness of the up quark mass.

- The second column of eq. (4.7) is mainly responsible for the solar neutrino mass and mixing. The second column is also responsible for the Cabibbo angle, providing the Cabibbo connection between quark and lepton mixing. We saw that the Cabibbo angle is given at LO by $\theta_C \approx 1/4$, however the HO corrections will modify this prediction, along with the PMNS predictions.

- The third column of eq. (4.7) is approximately decoupled from the see-saw mechanism due to the smallness of $m_1$ (the SD mechanism) and so is unimportant for lepton mixing. However the third column is responsible for the small quark mixing angles and quark CP violation. It is also responsible for the top quark Yukawa coupling.
4.3 Higher order corrections to quark mixing

The up quark Yukawa matrix defined by

\[ L = -v^u Y^u_{ij} L^u_i L^u_j + \text{h.c.} \]

is diagonalised by,

\[ U_{ul} Y^u U_{ul}^\dagger = \begin{pmatrix} y_u & 0 & 0 \\ 0 & y_c & 0 \\ 0 & 0 & y_t \end{pmatrix}. \] (4.8)

The CKM matrix is given by

\[ U_{CKM} = U_{ul} U^\dagger_{dl}, \] (4.9)

where \( U_{dl} \) is a diagonal matrix of phases since \( Y^d \) is diagonal. We use the PDG parameterization in the standard notation

\[ U_{CKM} = R^{q}_{23} U^q_{13} R^q_{12}, \] (4.10)

implies that \( U_{ul} \) is determined by,

\[ U_{ul} \cdot \begin{pmatrix} d & p & s \\ e & q & t \\ f & r & u \end{pmatrix} = \begin{pmatrix} * & 0 & 0 \\ * & 0 & 0 \\ * & * & * \end{pmatrix}. \] (4.11)

This is the same procedure that was followed for right-handed charged lepton sequential dominance [54]. Indeed here we have an analogous right-handed up-quark sequential dominance, with the third right-handed up quark dominating over the second, which in turn dominates over the first in their contributions to the up quark Yukawa matrix in eq. (4.10).

We hence obtain for the CKM parameters, writing \( t^q_{ij} = \tan(\theta^q_{ij}) \),

\[ e^{i\beta_2} t^q_{12} \approx -s_u^q + p_r^q \approx -\frac{1}{4} (1 + e_{12} - \varepsilon_{22} + \varepsilon_{23}/2 - 2\varepsilon_{13}), \] (4.12a)

\[ e^{-i\delta^q} e^{i\beta_2} s^q_{13} \approx -\frac{(c^q_{12} s + c^q_{12} e^{i\beta_2} t)}{u} \approx -\left( e^{q}_{12} \varepsilon_{13} + s^q_{12} e^{i\beta_2} \varepsilon_{23} \right), \] (4.12b)

\[ e^{i\beta_3} t^q_{12} \approx \frac{s^q_{12} s - c^q_{12} e^{i\beta_2} t}{c^q_{13} u} \approx \left( s^q_{12} \varepsilon_{13} - c^q_{12} e^{i\beta_2} \varepsilon_{23} \right). \] (4.12c)

The parameters \( \varepsilon_{ij} \) are complex and the phases on the l.h.s. of the above equations are fixed by the requirement that the mixing angles are real and positive. We have checked that these results very accurately reproduce the numerical results from the MPT package [39], to within an accuracy of better than 0.1% (taking into account the different conventions used there).

\[^6\text{Note that this convention for the quark Yukawa matrix differs by an Hermitian conjugation compared to that used in the Mixing Parameter Tools package [39] due to the RL convention used there.}\]
From the above results we find the simpler but less accurate approximations:

\[ \theta_{12}^q \approx \frac{1}{4} |1 + \varepsilon_{12} - \varepsilon_{22}|, \]  
(4.13a)

\[ \theta_{23}^q \approx | \varepsilon_{23} |, \]  
(4.13b)

\[ \theta_{13}^q \approx | \varepsilon_{23}/4 - \varepsilon_{13} |, \]  
(4.13c)

\[ \varepsilon_{13}^q \varepsilon_{23}^q \approx t_{12}^q - s_{13}^q \sin \delta^q. \]  
(4.13d)

Hence we find the following estimates:

- From (4.13a), the Cabibbo angle requires \(| \varepsilon_{12} - \varepsilon_{22} | \sim 0.07 \sim \mathcal{O}(\lambda^2)
- From (4.13b), \(V_{cb}\) is determined by \(| \varepsilon_{23} | \sim 0.04 \sim \mathcal{O}(\lambda^2)\)
- From (4.13c), \(V_{ub}\) is determined by \(| \varepsilon_{23}/4 - \varepsilon_{13} | \sim \mathcal{O}(\lambda^3)\)
- From (4.13d), the CP phase \(\delta^q \sim 70^\circ\) requires \(\text{Arg}(\varepsilon_{13}^q \varepsilon_{23}^q) \sim 22^\circ\) and \(| \frac{s_{13}^q}{s_{23}^q} | \sim 0.22\)

The ratio \(| \frac{\varepsilon_{13}^q}{\varepsilon_{23}^q} | \sim 0.22\) is close to the value \(| \frac{\varepsilon_{13}}{\varepsilon_{23}} | \sim 1/4\) expected from the vacuum alignments.

### 4.4 Higher order corrections to lepton mixing

We expect the neutrino Yukawa matrix which to have similar corrections to those previously considered for the up quark sector. However, as already mentioned, the HO corrections appearing in the third column of the Yukawa matrix, in particular \(\varepsilon_{13}, \varepsilon_{23}\), which are necessary for obtaining the small quark mixing angles and quark CP violation, will be relatively unimportant for lepton mixing. On the other hand, the HO corrections appearing in the first column of the Yukawa matrix, are unimportant for quark mixing but will affect lepton mixing. Only the HO corrections in the second column are important for both quark and lepton mixing, \(\varepsilon_{12}, \varepsilon_{22}\) are important for correcting the Cabibbo angle.

The important message from the quark sector is that one expects that all the HO corrections relevant for quark mixing angles to be small, and so we may infer that the neutrino Yukawa matrix involves similar corrections \(| \varepsilon_{ij} | \lesssim \lambda^2\), where \(\lambda = 0.225\) is the Wolfenstein parameter. In addition the right-handed neutrino mass matrix may gain small off-diagonal entries at HO due to the operators discussed previously, which will lead to further additional corrections unrelated to the quark sector. However, as discussed, if flavour is broken well below the PS breaking scale then such Majorana corrections are negligible. Therefore, we need only consider the effect of small corrections \(| \varepsilon_{ij} |\) to the elements of the neutrino Yukawa matrix, with the most important corrections arising from the first two columns.\footnotemark

\[ Y^\nu = \begin{pmatrix} \varepsilon_{11}/ae^2 & be(1 + \varepsilon_{12})/4\varepsilon_{23} & \varepsilon_{13}/ae^2 \varepsilon_{23}/(1 + \varepsilon_{31}) & 2b(1 + \varepsilon_{32}) \end{pmatrix}. \]  
(4.14)

\footnotetext{Note that \(Y^\nu\) is diagonalised by \(U_{\nu\nu}^U Y^\nu U^\dagger_{\nu\nu}\), where \(U_{\nu\nu}^U\) is not the same as \(U_{\nu\nu}\) in eq. (3.5). In fact \(U_{\nu\nu}^U\) is rather similar (but not identical due to Clebsch factors) to \(U_{\nu\nu}\), which diagonalises the up quark Yukawa matrix in eq. (4.8). Therefore \(U_{\nu\nu}^U\) is also of similar form to the CKM matrix, \(U_{\nu\nu}^U \sim U_{\text{CKM}}\).}
The corrections in the third column are not important for lepton mixing, but we include them in the scans. Due to Clebsch factors in the HO corrections, we consider the neutrino corrections to be independent of the up quark corrections, but of the same order of magnitude.

In figure 4 we show the predictions for the PMNS atmospheric and solar angles and all the phases, obtained from the Yukawa matrix in eq. (4.14) as a function of the ratio $\epsilon_\nu = m_b/m_a$ where we have implemented the see-saw mechanism leading to a light effective Majorana neutrino mass matrix as in eq. (3.7), but involving the HO corrections $\epsilon_{ij}$. In figure 5 we show a blow-up of the atmospheric and solar angle predictions, together with the Dirac CP violating oscillation phase. The reactor angle has a stronger correlation with $\epsilon_\nu = m_b/m_a$ and hence $m_2/m_3$ as shown in figure 6. These results may be compared to the LO predictions shown in table 4. In figures 4, 5, 6 we have randomly scanned over the independent (uncorrelated) complex parameters $\epsilon_{ij}$ which are allowed to take complex values with real and imaginary parts randomly chosen between $-0.02$ and $0.02$, limiting the modulus to be less than about $0.03$. In the scans we have assumed that the corrections $\epsilon_{11}$ and $\epsilon_{13}$ are smaller by a factor of 1/4 than the other corrections, $|\epsilon_{11}|/|\epsilon_{21}| \sim 1/4$ and $|\epsilon_{13}|/|\epsilon_{23}| \sim 1/4$, due to the pattern of alignments in eq. (2.5). This assumption is consistent with the fact that in the quark sector we require $|\epsilon_{11}|/|\epsilon_{21}| \sim 0.22$.

From the plots in figures 4, 5, 6 we estimate the approximate one sigma ranges for the theoretical predictions of the atmospheric and solar angles of $\theta_{23}^l = 40^\circ \pm 1^\circ$, $\theta_{12}^l = 34^\circ \pm 1^\circ$, with a reactor angle $\theta_{13}^l = 9.0^\circ \pm 0.5^\circ$, correlated with $m_2/m_3$. We also predict the Dirac CP violating oscillation phase to be $\delta^l = 260^\circ \pm 5^\circ$. The predictions of the tetra-model of a normal hierarchy of neutrino masses with an atmospheric angle in the first octant will be tested quite soon. We emphasise that the above errors arise from the
Figure 5. Left panel shows a zoom-in of the predictions for the atmospheric angle $\theta_{23}^l$ (upper) and solar angle $\theta_{12}^l$ (lower) in the presence of HO corrections. Right panel shows a zoom-in of the predictions for the Dirac oscillation phase $\delta^l$ (in degrees) in the presence of HO corrections. The predictions are presented as a function of $\epsilon = m_b/m_a$ and hence $m_2/m_3$, for $m_1 = 0.3$ meV and $m_2 = 50$ meV. Note that these predictions assume $\eta = 2\pi/5$. The predictions are obtained numerically using the Mixing Parameter Tools (MPT) package based on [39], taking into account the different conventions.

Figure 6. Left panel shows a zoom-in of the predictions for the reactor angle $\theta_{13}^l$ as a function of $\epsilon = m_b/m_a$, in the presence of HO corrections. Right panel the predictions for the neutrino mass ratio $m_2/m_3$ as a function of $\epsilon = m_b/m_a$, in the presence of HO corrections. Taken together, these plots show how the reactor angle prediction increases with $m_2/m_3$. The predictions are presented for $m_1 = 0.3$ meV and $m_2 = 50$ meV. Note that these predictions assume $\eta = 2\pi/5$. The predictions are obtained numerically using the Mixing Parameter Tools (MPT) package based on [39], taking into account the different conventions.

same higher order corrections which are solely responsible for the small quark mixing angles. This gives a handle on the size of the irreducible theoretical error that must be included in the leptonic predictions. In addition, we expect additional corrections of possibly similar magnitude arising from renormalisation group (RG) running [55] and canonical normalisation corrections [56–58]. For example in SUSY GUT models and light sequential dominance, similar to the case here, the RG corrections for high $\tan \beta \sim 50$ are [55]: $\Delta \theta_{23}^l \sim +1^\circ$, $\Delta \theta_{12}^l \sim +0.4^\circ$, $\Delta \theta_{13}^l \sim -0.1^\circ$, where the “+” sign means that the value increases in running from the GUT scale to low energy, while for low $\tan \beta < 10$ the RG corrections are negligible. Clearly the RG corrections provide additional shifts
in the central values of the predicted angle, but the shifts lie within the errors quoted above arising from HO corrections, and for low $\tan \beta \lesssim 10$ such RG shifts are negligible. Clearly knowledge of the error in the leptonic predictions is crucial since such predictions will be subject to intense experimental scrutiny over the coming years and will serve to test the tetra-model.

5 Conclusions

In this paper we have proposed a tetra-model of quark and lepton mixing based on tetrahedral $A_4$ family symmetry and the tetra-colour Pati-Salam group $SU(4)_{PS}$ together with $SU(2)_L \times U(1)_R$ and the tetra-vacuum alignment $(1, 4, 2)$. Leptonic mixing and CP violation is fully predicted at leading order, as a consequence of the vacuum alignment. In addition, a Cabibbo angle $\theta_C \approx 1/4$ emerges from the tetra-alignment $(1, 4, 2)$, which appears in the second column common to the neutrino and up quark Yukawa matrices, providing the Cabibbo connection between quark and lepton mixing.

Due to the requirement of having diagonal down and charged lepton Yukawa matrices, with all quark and lepton mixing originating from the up and neutrino Yukawa matrices, we do not impose the $SU(2)_R$ gauge group, only its diagonal subgroup $U(1)_R$ where $R = T^3_R$, the third (diagonal) $SU(2)_R$ generator. For this reason, and also the fact that the left-handed and right-handed quarks and leptons transform differently under $A_4$, the tetra-model cannot (easily) be embedded into $SO(10)$ at the field theory level. However, we speculate that it may be possible to obtain the tetra-model directly from string theories such as heterotic string theory, F-theory or M-theory in which $SO(10)$ is present in extra dimensions. Supersymmetry (SUSY) is motivated by both string theory and the vacuum alignment mechanism, as well as gauge coupling unification and dark matter, however there are no other compelling reasons why the tetra-model could not be formulated as a non-SUSY model.

The leading order Yukawa matrices and Majorana neutrino mass matrix have a remarkably simple form as shown in eqs. (3.1), (3.2), involving only nine real parameters, namely $y_d, y_s, y_b, |a|, |b|, |c|$ and $M_1, M_2, M_3$ (where we may absorb the powers of $\epsilon$) leading to the predictions summarised in section 3. The charged lepton masses are related to down quark masses by GJ relations. Dirac neutrino masses are equal to up quark masses, up to Clebsch-Gordan coefficients, while Majorana neutrino masses are proportional to the squares up type quark masses, giving an $SO(10)$-like pattern. However in our model the strong hierarchies naturally cancel in the see-saw mechanism, leading to a normal neutrino mass hierarchy. Lepton mixing angles and all CP phases are predicted as a function of the neutrino mass ratio $m_2/m_3$, with the angles being affected by about one degree from the results in the previous two right-handed neutrino model due to the non-zero lightest neutrino mass.

At leading order, the model provides a good description of the twelve fermion masses (including the light three neutrino masses) as well as the six PMNS parameters and the Cabibbo angle: a total of nineteen physical observables from nine input parameters, which is ten fewer parameters than in the SM. The ten leading order predictions include the
six PMNS parameters, three charged lepton-down quark mass relations and the Cabibbo angle. The lepton mixing angles and the Cabibbo angle can be understood as arising from the vacuum alignment of the $A_4$ family symmetry breaking flavons. Leptonic CP violation arises from a relative phase of $-4\pi/5$ between $Z_5$ breaking flavon VEVs which appear in the construction of the neutrino mass matrix in eq. (3.8). This phase is essential in obtaining the correct leptonic mixing angles although it plays no simple role in the quark mixing angles since the Cabibbo angle is independent of this phase and the other quark mixing angles and CP phase are zero at the leading order. The remaining 3 parameters, namely the two small quark mixing angles $\theta_{13}^q, \theta_{23}^q$ associated with $V_{ub}, V_{cb}$ and the CP violating phase $\delta^q$, are zero at leading order and originate from a large number of higher order operators. The higher order operators also correct Cabibbo angle and PMNS parameters, leading to some theoretical error or “noise” in the leading order predictions.

One of the main successes of the tetra-model is that it provides an explanation for why the Cabibbo angle and lepton mixing angles take the “large” values that they do, as a result of the vacuum alignment of the $A_4$ symmetry breaking flavons, while the remaining quark mixing angles are “small” since they are zero at leading order and become non-zero due to higher order corrections. The model provides an explanation for the size of the Cabibbo angle and its role as the link between quark and lepton mixing (the Cabibbo connection). The higher order corrections also affect the Cabibbo angle and PMNS parameters, providing a source of theoretical error or “noise” which blurs the leading order predictions. In the case of the Cabibbo angle, such “noise” is in fact necessary in order to bring the leading order prediction of $\theta_C \approx 14^\circ$ into precise agreement with experiment where $\theta_C \approx 13^\circ$. In the case of the lepton mixing angles, the “noise” provides a guide to the experimental accuracy required in order to test the model.

It is worth briefly discussing the experimental prospects for testing the predictions of the tetra-model. The “binary” predictions of a normal neutrino mass hierarchy and an atmospheric angle in the first octant will both be tested over the next few years by current and planned neutrino experiments such as SuperKamiokande, T2K, NOνA and PINGU [49–52]. The Daya Bay II reactor experiment, including the short baseline detectors [59, 60], will also test the neutrino mass hierarchy and in addition measure the reactor and solar angle to high accuracy, enabling precision tests of the predictions $\theta_{13} = 9.0^\circ \pm 0.5^\circ$ and $\theta_{12} = 34^\circ \pm 1^\circ$. In the longer term, superbeam and neutrino factory proposals such as WBB and LENF [61] would measure the atmospheric mixing angle to high accuracy, confronting the prediction $\theta_{23} = 40^\circ \pm 1^\circ$, and ultimately testing the prediction of the Dirac CP violating oscillation phase $\delta^l = 260^\circ \pm 5^\circ$.

In conclusion, the tetra-model is a robust theory of flavour based on quark-lepton-family unification. It solves many of the flavour puzzles, halving the number of parameters in the flavour sector of the SM. At leading order, the tetra-model remarkably gives ten predictions, somewhat blurred by the higher order corrections as we have discussed. It also qualitatively explains the smallness of the quark mixing angles compared to lepton mixing angles, with the former being zero at leading order, apart from the Cabibbo angle which is given by $\theta_C \approx 1/4$, due to the tetra-vacuum alignment $(1, 4, 2)$, providing the Cabibbo connection between quark and lepton mixing. The tetra-model involves an SO(10)-like
pattern of Dirac and heavy right-handed neutrino masses, with the strong up-type quark mass hierarchy cancelling in the see-saw mechanism, leading to a relatively mild normal hierarchy of neutrino masses. The tetra-model yields fairly accurate predictions for all six PMNS mixing parameters (three angles as well as three phases) and predicts a normal neutrino mass hierarchy with the atmospheric angle in the first octant. It will be decisively tested over the coming years by presently running and future neutrino experiments.
