A MODULAR CONSTRUCTION OF UNRAMIFIED $p$-EXTENSIONS OF $\mathbb{Q}(N^{1/p})$

JACLYN LANG AND PRESTON WAKE

Abstract. We show that for primes $N, p \geq 5$ with $N \equiv -1 \mod p$, the class number of $\mathbb{Q}(N^{1/p})$ is divisible by $p$. Our methods are via congruences between Eisenstein series and cusp forms. In particular, we show that when $N \equiv -1 \mod p$, there is always a cusp form of weight 2 and level $\Gamma_0(N^2)$ whose $\ell$-th Fourier coefficient is congruent to $\ell + 1$ modulo a prime above $p$, for all primes $\ell$. We use the Galois representation of such a cusp form to explicitly construct an unramified degree $p$ extension of $\mathbb{Q}(N^{1/p})$.

1. Introduction

Throughout this paper, $N$ and $p$ denote prime numbers such that $p \geq 5$.

1.1. Main results. We give a proof of the following theorem via congruences between Eisenstein series and cuspidal modular forms.

Theorem A. If $N \equiv -1 \mod p$ then $p$ divides the class number of $\mathbb{Q}(N^{1/p})$.

This theorem was conjectured by Kobayashi [Kob16, Conjecture 1], who proved it in the case $p = 5$. A proof of Theorem A using Galois cohomology was sketched by Calegari on his blog [Cal]. Calegari asks whether there is a direct proof of Theorem A and whether there is “an easy way to construct the relevant unramified extension of degree $p$”. The purpose of this paper is to do exactly that.

We give an explicit construction of the corresponding unramified extension of degree $p$ of $\mathbb{Q}(N^{1/p})$ using the Galois representation of a modular form. Explicitly, we prove the following.

Theorem B. Assume that $N \equiv -1 \mod p$.

(a) There is a newform $f$ of weight 2 and level $\Gamma_0(N^2)$ and a prime ideal $\mathfrak{p}$ over $p$ in the ring of integers $\mathcal{O}_f$ of the Hecke field of $f$ such that for all primes $\ell$,

$$a_\ell(f) \equiv 1 + \ell \mod \mathfrak{p}.$$  

(b) Moreover, if $s$ is the largest integer such that $a_\ell(f) \equiv 1 + \ell \mod \mathfrak{p}^s$ for all primes $\ell \neq N$ and $t_f : \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \to \mathcal{O}_{f, \mathfrak{p}}$ denotes the trace of the Galois representation of $f$, then

$$t_f|\text{Gal}(\mathbb{Q}(N^{1/p})/\mathbb{Q}) \equiv \chi \ell + \chi^{-1} \mod \mathfrak{p}^{s+1},$$

where $\epsilon$ is the $p$-adic cyclotomic character and $\chi : \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(N^{1/p})) \to (\mathcal{O}_{f, \mathfrak{p}}/\mathfrak{p}^{s+1})^\times$ is a non-trivial everywhere unramified character with $\chi \equiv 1 \mod \mathfrak{p}^s$.

The values $1 + \ell$ on the right hand side of (1) are the Hecke eigenvalues of an Eisenstein series, so we say that a form $f$ satisfying (1) for all primes $\ell \neq N$ is congruent to an Eisenstein series, and say (1) is an Eisenstein congruence, modulo $p$.

Remark 1.1. For level $\Gamma_0(M)$ with $M$ prime, Mazur [Maz77] gave a necessary and sufficient condition for an Eisenstein congruence to exist. For squarefree $M$, partial necessary and sufficient conditions have been found by Ribet [Rib10] (see also [Yoo19a]) using geometry of modular Jacobians, and by the second author and Wang-Erickson [WWE21] using Galois deformation theory. For some nonsquarefree $M$, sufficient conditions have been proven by Martin [Mar17] using Jacquet–Langlands theory and necessary conditions by Yoo [Yoo19b] using geometry of modular Jacobians. However, both those works do not consider the case where $M$ is a square of a prime. The case where $M$ is a square of a prime has been considered by Gross–Lubin [GL86] and Calegari [Cal06], but only then when $p \mid M$.

Key words and phrases. Eisenstein ideal, class group, Galois representation.
Note that Theorem B implies Theorem A by class field theory, because \( \chi \) cuts out a degree-\( p \) unramified extension of \( \mathbb{Q}(N^{1/p}) \). Theorem B may be thought of as an explicit version of Theorem A because the Fourier coefficients of the newform \( f \) can often be efficiently computed. Extra information about the class field of \( \mathbb{Q}(N^{1/p}) \) can be read off from this data, as we illustrate in Section 3.2.

1.2. The \( N \equiv 1 \mod p \) case. To understand the context for Theorems A and B, we recall what is known in the case when \( N \equiv 1 \mod p \) — a congruence condition we impose throughout Section 1.2. In this case, it is easy to see that \( \text{Cl}(\mathbb{Q}(N^{1/p}))[p] \) — the \( p \)-torsion in the class group of \( \mathbb{Q}(N^{1/p}) \) — is non-trivial: there is a degree-\( p \) subextension \( \mathbb{Q}(\zeta_N^{(p)}) \) of \( \mathbb{Q}(\zeta_N)/\mathbb{Q} \) and \( \mathbb{Q}(\zeta_N^{(p)},N^{1/p})/\mathbb{Q}(N^{1/p}) \) is unramified. Letting
\[ r_{\text{CI}} = \dim_{\mathbb{F}_p} \text{Cl}(\mathbb{Q}(N^{1/p}))[p] \]
we can see \( r_{\text{CI}} \geq 1 \), but the exact value of \( r_{\text{CI}} \) is interesting. In particular, it is interesting to ask when \( r_{\text{CI}} > 1 \), or, in other words, when there is an unramified \( p \)-extension of \( \mathbb{Q}(N^{1/p}) \) that is not explained by genus theory.

On the modular forms side, Mazur [Maz77, Proposition II.9.7] proved that there is a cuspform \( f \) of weight 2 and level \( \Gamma_0(N) \) that is congruent to the Eisenstein series modulo \( p \) if and only if \( N \equiv 1 \mod p \). Letting \( S_2(\Gamma_0(N);\mathbb{Z}_p)_{\text{Eis}} \) denote the completion of the space of cusp forms at the Eisenstein maximal ideal, and letting
\[ r_{\text{Eis}} = \text{rank}_{\mathbb{Z}_p} S_2(\Gamma_0(N);\mathbb{Z}_p)_{\text{Eis}}, \]
Mazur’s result implies \( r_{\text{Eis}} \geq 1 \), but he also asked what the significance of \( r_{\text{Eis}} \) is in general [Maz77, Section II.19, page 140].

The first result about \( r_{\text{Eis}} \) was obtained by Mazur [Maz77, Proposition II.19.2, pg. 140], who showed that \( r_{\text{Eis}} = 1 \) if and only if the Weil pairing on \( J_0(N) \) has a certain property. Merel used modular symbols and Mazur’s result to prove a remarkable numerical criterion for \( r_{\text{Eis}} \) to equal 1 [Mer96, Théorème 2]. More recently, Lecouturier has greatly generalized Merel’s techniques to relate the value of \( r_{\text{Eis}} \) to “higher Merel invariants”.

Calegari and Emerton [CE05] were the first to find a relationship between \( r_{\text{Eis}} \) and \( r_{\text{CI}} \). They proved
\[ r_{\text{Eis}} = 1 \implies r_{\text{CI}} = 1 \]
using Galois deformation theory and explicit class field theory. Later, Lecouturier [Lec18] used Merel’s result to give a new proof of (2) by purely algebraic-number-theoretic methods.

The second author and Wang-Erickson refined Calegari and Emerton’s method to precisely determine the value of \( r_{\text{Eis}} \) in terms of vanishing of a certain cup product (or, more generally, Massey product) in Galois cohomology [WWE20]. In particular, they show that \( r_{\text{Eis}} = 1 \) if and only if a certain cup product vanishes [WWE20, Theorem 1.2.1]. They also show that the vanishing of this cup product implies \( r_{\text{CI}} > 1 \), hence giving a new proof of (2). Schaefer and Stubley [SS19] built upon this cup product technique and the results of [Lec18] to prove more precise bounds on \( r_{\text{CI}} \).

1.3. Comparing \( N \equiv 1 \mod p \) and \( N \equiv -1 \mod p \). When \( N \equiv -1 \mod p \), in contrast to the previous section, the genus field of \( \mathbb{Q}(N^{1/p}) \) is trivial. Hence we see Theorem A as analogous to “\( r_{\text{CI}} > 1 \)” of the previous section.

When \( N \equiv -1 \mod p \), then Mazur’s results imply that \( S_2(\Gamma_0(N);\mathbb{Z}_p)_{\text{Eis}} \) is trivial. Instead, we study \( S_2(\Gamma_0(N^2);\mathbb{Z}_p(\zeta_N))_{\text{Eis}} \) and Theorem B implies that this is non-trivial. We think of this as being analogous to “\( r_{\text{Eis}} > 1 \)” of the previous section.

The surprising thing is that, although “\( r_{\text{CI}} > 1 \)” and “\( r_{\text{Eis}} > 1 \)” do not always hold for \( N \equiv 1 \mod p \), their analogs for \( N \equiv -1 \mod p \) do always hold. Just as “\( r_{\text{CI}} > 1 \)” and “\( r_{\text{Eis}} > 1 \)” are related to the vanishing of a cup product, their analogs for \( N \equiv -1 \mod p \) are also related to the vanishing of a cup product. The difference is that, when \( N \equiv -1 \mod p \), the relevant cup product always vanishes because the codomain \( H^2 \) group vanishes. Indeed, this is the observation that Calegari made after attending a lecture by the second author about the work of [WWE20] explaining the relation between cup products and the class group of \( \mathbb{Q}(N^{1/p}) \) that allowed him to give a Galois cohomology proof of Theorem A using the methods of [WWE20].
1.4. **Eisenstein congruences in the case** $N \equiv -1 \text{ mod } p$. The purpose of this paper is to show that, just as in [WWE20], the abstract Galois cochain used in [Cal] actually appears in the Galois representation associated to a newform. The newform we need has to be congruent to an Eisenstein series, but Mazur’s theorem implies that there is no such newform of level $\Gamma_0(N)$ when $N \equiv -1 \text{ mod } p$. Our motivation came from considering the obstruction, from the point of view of Galois deformation theory, to producing the relevant Galois representation. The observation we made is that there is no obstruction to producing such a representation that is unramified outside $N$ and $p$; the only obstruction comes from making it be Steinberg at $N$. Consequently, if we relax the local condition at $N$ by considering forms of level $\Gamma_0(N^2)$, we expect to find a newform that is congruent to the Eisenstein series. Although these deformation-theoretic considerations led us to conjecture that Theorem B should be true, the proof does not use deformation theory; it is a direct computation using Eisenstein series. 

Remark 1.2. In fact, Kobayashi conjectures that for any positive integer $m$ that is divisible by a prime $\ell \equiv -1 \text{ mod } p$, the class number of $\mathbb{Q}(m^{1/p})$ should be divisible by $p$ [Kob16, Conjecture 1]. Calegari explains how to use cup products to prove Kobayashi’s conjecture in full generality [Cal]. We believe a modular approach is also possible by combining the methods of the current paper with those of the second author and Wang-Erickson in [WWE21], but we have elected not to do so in this paper for simplicity. △

1.5. **Layout.** In Section 2 we establish the Eisenstein congruence promised in Theorem B(a). There are no Galois representations in this section; the main calculation is to compute the constant terms at the cusps of an Eisenstein series. We then derive the consequences of this congruence for Galois representations and the class group of $\mathbb{Q}(N^{1/p})$ in Section 3, thus proving Theorem B(b) and hence Theorem A. We end by showing, in Section 3.2, how explicit information about the Fourier coefficients of the modular form found in Theorem B gives explicit information about the primes that split in the class field of $\mathbb{Q}(N^{1/p})$, thus demonstrating the advantages of a modular proof of Theorem A.

**Notation.** For a positive integer $n$, let $\zeta_n$ denote a primitive $n$-th root of unity. When $S$ is a subset of $M_2(\mathbb{R})$, we write $S^+$ for the subset of $S$ with positive determinant. For a field $F$ of characteristic 0, fix an algebraic closure $\overline{F}$. Write $G_F := \text{Gal}(\overline{F}/F)$, which we may implicitly view as a subgroup of $G_{\mathbb{Q}}$ when $F$ is a number field. Let $G_{\mathbb{Q}, Np}$ denote the Galois group of the maximal extension of $\mathbb{Q}$ that is unramified outside $Np$. We fix an embedding $\mathbb{Q} \hookrightarrow \overline{\mathbb{Q}}_p$ and let $I_{\mathbb{Q}}$ denote the corresponding inertia subgroup of $G_{\mathbb{Q}}$. Let $\varepsilon : G_{\mathbb{Q}} \to \mathbb{Z}_p^\times$ be the $p$-adic cyclotomic character and $\omega$ its mod $p$ reduction. We write $\mathbb{Z}_p$ for the elements in $\overline{\mathbb{Q}}_p$ that are integral over $\mathbb{Z}_p$. If $X$ is a scheme, then $\mathcal{O}_X$ denotes its structure sheaf.

2. **Eisenstein series and residues**

2.1. **The modular curve** $X_0(N^2)$ and its cusps. Recall that $N$ and $p$ always denote distinct primes, and $p \geq 5$. Define

$$\Gamma := \Gamma_0(N^2) := \left\{ \left( \begin{array}{cc} a & b \\ Nc & d \end{array} \right) \in \text{SL}_2(\mathbb{Z}) : c \in \mathbb{Z} \right\},$$

which acts on the upper half complex plane $\mathfrak{h}$ by Möbius transformations. The open Riemann surface $\Gamma \setminus \mathfrak{h}$ can be compactified to $\Gamma \setminus \mathfrak{h}^*$ by adding the cusps $\Gamma \setminus \mathbb{P}^1(\mathbb{Q})$. The complex curves $\Gamma \setminus \mathfrak{h} \subset \Gamma \setminus \mathfrak{h}^*$ descend to $\overline{\mathbb{Q}}$ and admit a smooth model over $\mathbb{Z}[1/N]$. Let $Y := Y_0(N^2) \subset X := X_0(N^2)$ denote the base change of these smooth models to $\mathbb{Z}_p[\zeta_N]$.

Let $C := X \setminus Y$ denote the scheme of cusps on $X$. A standard calculation shows that there are $N + 1$ geometric points of $C$ [DS05, §3.8], all defined over $\mathbb{Z}_p[\zeta_N]$ [DR73, §VI.5], represented by the following elements in $\mathbb{P}^1(\mathbb{Q}) = \mathbb{Q} \cup \{\infty\}$:

$$\infty, 0, 1/N, 2/N, \ldots, (N - 1)/N.$$

We sometimes conflate $C$ with its set of geometric points. It will be convenient to consider $(\mathbb{Z}/N\mathbb{Z})^\times$ as the indexing set for the set $C \setminus \{\infty, 0\}$. For $x \in (\mathbb{Z}/N\mathbb{Z})^\times$, we define $[x] \in C$ to be the class of $\bar{x} N / N \in \mathbb{P}^1(\mathbb{Q})$, where $1 \leq \bar{x} \leq N - 1$ such that $\bar{x} \equiv x \text{ mod } N$. Similarly, write $[0]$ for the cusp 0 to avoid confusion. We write $\text{Div}(C; \mathbb{Z}_p[\zeta_N])$ for the divisor group supported on the cusps and $\text{Div}^0(C; \mathbb{Z}_p[\zeta_N])$ for the degree-0 part.
2.2. Modular forms and the residue sequence. Let $\Omega = \Omega_X$ be the invertible sheaf of 1-forms on $X$ over $\mathbb{Z}_p[\zeta_N]$. Viewing $C$ as a divisor on $X$ we have the sheaf $\Omega(C) = \Omega \otimes \mathcal{O}_X(C)$ of 1-forms on $X$ where we allow simple poles at $C$. Define the space of modular forms (respectively, cusp forms) of weight 2 and level $\Gamma$ with coefficients in $\mathbb{Z}_p[\zeta_N]$ by $M_2(\Gamma; \mathbb{Z}_p[\zeta_N]) := H^0(X, \Omega(C))$ (respectively, $S_2(\Gamma; \mathbb{Z}_p[\zeta_N]) := H^0(X, \Omega)$). Note that this definition is compatible with the usual definition. That is, fixing an isomorphism $\Omega_p \cong \mathbb{C}$, we can identify $M_2(\Gamma; \mathbb{Z}_p[\zeta_N])$ with the subspace $M_2(\Gamma; \mathbb{C})$ whose $q$-expansions have $\mathbb{Z}_p[\zeta_N]$-coefficients since $p \nmid N^2$ [Maz77, Lemma II.4.5].

**Proposition 2.1.** There is an exact sequence

$$0 \to S_2(\Gamma; \mathbb{Z}_p[\zeta_N]) \to M_2(\Gamma; \mathbb{Z}_p[\zeta_N]) \xrightarrow{\text{Res}} \text{Div}(C; \mathbb{Z}_p[\zeta_N]) \xrightarrow{\Sigma} \mathbb{Z}_p[\zeta_N] \to 0,$$

where $\text{Res}$ sends a modular form to the formal sum of its residues at the cusps, and $\Sigma$ is the sum map.

**Proof.** Set $W = \mathbb{Z}_p[\zeta_N]$. For $c \in C$, the inclusion $\iota_c : c \to X$ comes with a map $\mathcal{O}_X \to \iota_{cs}(W)$ with kernel $\mathcal{O}_X(-c)$. Putting them together gives a short exact sequence of sheaves

$$0 \to \mathcal{O}_X(-C) \to \mathcal{O}_X \to \bigoplus_{c \in C} \iota_{cs}(W) \to 0$$

that when tensored with $\Omega(C)$ yields

$$0 \to \Omega \to \Omega(C) \to \bigoplus_{c \in C} \Omega(C) \otimes \iota_{cs}(W) \to 0.$$

The associated long exact sequence in cohomology gives the following exact sequence of $W$-modules

$$0 \to H^0(X, \Omega) \to H^0(X, \Omega(C)) \to \bigoplus_{c \in C} H^0(X, \Omega(C) \otimes \iota_{cs}(W)) \to H^1(X, \Omega).$$

The projection formula and the fact that $\Omega(C)$ is locally free of rank 1 imply that $H^0(X, \Omega(C) \otimes \iota_{cs}(W)) = W$. Using the fact that $H^1(X, \Omega)$ is a finitely generated $W$-module together with base change theorems and Serre duality over $W[1/p]$ and $W/p$, we see that $H^1(X, \Omega) = W$. Tensoring (5) with $W[1/p]$ and using base change theorems, we see from [Oht99, Lemma 3.1.13(ii)] that $H^0(X, \Omega(C)) \to \bigoplus_{c \in C} W$ is the residue map and the map $\bigoplus_{c \in C} W \to W$ is just the sum, which is clearly surjective. \qed

We briefly recall the formula for the residue map $\text{Res}$ in terms of constant terms of $q$-expansions of modular forms; see [Oht99, §4.5] for more details. Given $c \in C(\mathbb{Z}_p[\zeta_N])$, its width is a positive integer $h_c$ such that, up to sign, the stabilizer of $c$ in $\Gamma$ can be conjugated to

$$\left\langle \begin{pmatrix} 1 & h_c \\ 0 & 1 \end{pmatrix} \right\rangle.$$

In our case, $\infty$ has width 1, $[0]$ has width $N^2$, and all the other cusps of $X$ have width $N$. The Fourier expansion of $f \in M_2(\Gamma; \mathbb{Z}_p[\zeta_N])$ at $c$ is of the form

$$f = \sum_{n=0}^{\infty} a_c^n(f) q^{n/h_c},$$

and

$$\text{Res}(f) = \sum_{c \in C(\mathbb{Z}_p[\zeta_N])} h_c a_0^n(f)c.$$  

That is, writing $\text{Res}_i(f)$ for the coefficient of $c$ in $\text{Res}(f)$, we have $\text{Res}_i(f) = h_i a_0^n(f)$. Note that for the cusp $[0]$, the Atkin-Lehner involution $w_{N^2}$ incorporates the width of $[0]$, and hence $\text{Res}_{[0]}(f) = a_0^n(w_{N^2} f)$.

2.3. Hecke operators. The Hecke operators $T_\ell$ for primes $\ell \nmid N$ and $U_N$ act on $M_2(\Gamma; \mathbb{Z}_p[\zeta_N])$ and this action preserves $S_2(\Gamma; \mathbb{Z}_p[\zeta_N])$. By the sequence (4), this gives an induced action on $\text{Div}^0(C; \mathbb{Z}_p[\zeta_N])$. In fact, this action extends to $\text{Div}(C; \mathbb{Z}_p[\zeta_N])$ in a way that makes (4) Hecke-equivalent:

**Proposition 2.2.** Define an action of the Hecke operators $T_\ell$ with $\ell \nmid N$ and $U_N$ on $\text{Div}(C; \mathbb{Z}_p[\zeta_N])$ as follows:
(1) For a prime $\ell \neq N$ and $c \in C$ let
\[
T_\ell c = \begin{cases}
(\ell + 1)c & \text{if } c = 0, \infty \\
(\ell x) + [\ell^{-1} x] & \text{if } c = [x] \text{ for } x \in (\mathbb{Z}/N\mathbb{Z})^\times.
\end{cases}
\]

(2) For $c \in C$ let
\[
U_N c = \begin{cases}
N \cdot [0] & c \neq \infty \\
\infty + \sum_{x \in (\mathbb{Z}/N\mathbb{Z})^\times} [x] & c = \infty.
\end{cases}
\]

Then the sequence (4) is Hecke-equivariant.

**Proof.** Note that, to prove the proposition, it suffices to work with $\mathbb{Q}_p$-coefficients (or even $\mathbb{C}$-coefficients), so this is entirely classical. Note also that this is not the “standard” action of $U_N$, but rather the adjoint action. To explain why this is, we must fix our conventions for Hecke operators.

For any $\alpha \in \text{GL}_2(\mathbb{Q})^+$, let $\Gamma_\alpha = \Gamma \cap \alpha^{-1} \Gamma \alpha$. Then we have two maps $\Gamma_\alpha \backslash \mathfrak{h}^* \to \Gamma \backslash \mathfrak{h}^*$:
\[
\varphi_\alpha : \Gamma_\alpha \mathfrak{z} \mapsto \Gamma \mathfrak{z} \text{ and } \psi_\alpha : \Gamma_\alpha \mathfrak{z} \mapsto \Gamma \alpha \mathfrak{z}.
\]

Define $O_\alpha := \psi_\alpha \varphi_\alpha^*$ as an operator on all of the cohomology groups in (5) (base-changed to $\mathbb{C}$). For any prime $\ell$, let $\alpha_\ell := (1_0 \ 0_\ell)$, and let $T_\ell := O_{\alpha_\ell}$ and define $U_N := T_N$. With this definition, it is clear that (4) is Hecke-equivariant. To prove the proposition, it remains to see what this action is on $\text{Div}(C)$.

We now consider the standard action of Hecke operators on $\text{Div}(C)$. We have the identifications
\[
C = \Gamma \backslash \mathbb{P}^1(\mathbb{Q}) \xrightarrow{\sim} \Gamma \backslash \text{SL}_2(\mathbb{Z}) / B(\mathbb{Z}) \xrightarrow{\sim} \Gamma \backslash \text{GL}_2(\mathbb{Q})^+ / B(\mathbb{Q})^+,
\]
where $B \subset \text{SL}_2$ is the upper-triangular Borel. The inverse of the first map is given by sending the class of $\left( \begin{smallmatrix} a & b \\ c & d \end{smallmatrix} \right) \in \text{SL}_2(\mathbb{Z})$ to $[a : c] \in \mathbb{P}^1(\mathbb{Q})$, and the second map is induced by the natural inclusion $\text{SL}_2(\mathbb{Z}) \hookrightarrow \text{GL}_2(\mathbb{Q})^+$. For an element $\gamma \in \text{GL}_2(\mathbb{Q})^+$, let $[\gamma] \in C$ denote its class. For $\alpha \in \text{GL}_2(\mathbb{Q})^+$, the standard action of $O_\alpha$ on $C$ is given by $O_\alpha([\gamma]) = \sum [\alpha(i) \gamma]$, where $\Gamma \alpha \Gamma = \bigcup \{ \alpha \Gamma \alpha^{-1} \}$.

The key observation, which we learned from [Oht99, Proposition 3.4.12], is that the identification of $\bigoplus_{\gamma \in C} H^0(X_C, \Omega(C)_C \otimes_{\mathcal{O}_C} \mathbb{C}(\mathfrak{f}))$ with $\text{Div}(C)$ swaps standard Hecke operators with their adjoints. (Intuitively, this is because $\bigoplus_{\gamma \in C} H^0(X_C, \Omega(C)_C \otimes_{\mathcal{O}_C} \mathbb{C}(\mathfrak{f}))$ is the Serre-dual of $H^0(C, \mathcal{O}_C(\mathfrak{f}))$.) Equivalently, to make (4) Hecke-equivariant, $T_\ell$ has to act on $\text{Div}(C)$ via the standard action of $O_{\beta_\ell}$, where $\beta_\ell = (\begin{smallmatrix} \ell & 0 \\ 0 & 1 \end{smallmatrix})$.

Given this, the proposition follows from the following two lemmas, whose simple proofs we omit.

**Lemma 2.3.** For a prime $\ell$, let $\beta_\ell = (\begin{smallmatrix} \ell & 0 \\ 0 & 1 \end{smallmatrix})$.

1. Let $\ell \neq N$ be a prime. A set of representatives for $\Gamma \backslash \Gamma_\beta \Gamma$ is given by $\beta_\ell$ together with any $\ell$ matrices of the form
\[
\beta_\ell \left( \begin{smallmatrix} a & b \\ N^2 & d \end{smallmatrix} \right)
\]
where $ad - bN^2 = 1$ and $d$ ranges over a set of representatives of $\mathbb{Z}/\ell\mathbb{Z}$.

2. A set of representatives for $\Gamma \backslash \gamma N_\Gamma$ is given by the $N$ matrices
\[
\beta_N \left( \begin{smallmatrix} 1 & 0 \\ iN^2 & 1 \end{smallmatrix} \right)
\]
for $i = 0, \ldots, N - 1$.

**Lemma 2.4.** For an element $\gamma = \left( \begin{smallmatrix} a & b \\ c & d \end{smallmatrix} \right) \in \text{GL}_2(\mathbb{Q})^+$, we can determine its class in $C$ as follows. If $c = 0$ then the class of $\gamma$ is $\infty$. If $c \neq 0$, write $\frac{a}{c} = \frac{x}{y}$ with $x, y \in \mathbb{Z}$ coprime.

- If $N^2 \mid y$, then the class of $\gamma$ is $\infty$;
- If $N \nmid y$, then the class of $\gamma$ is $[0]$;
- If $y = uN$ with $N \nmid u$, then the class of $\gamma$ is $[ux \mod N]$.

\[ \square \]
2.4. Eisenstein series. To prove Theorem B(a), we consider congruences between elements of \( S_2(\Gamma; \mathbb{Z}_p[\zeta_N]) \) and an Eisenstein series with \( T_\ell \)-eigenvalue \( \ell + 1 \) for all primes \( \ell \neq N \). There are two such Eisenstein series in \( M_2(\Gamma; \mathbb{Z}_p[\zeta_N]) \), both old forms. We write them explicitly.

Define

\[
E_2(z) := \frac{-1}{24} + \sum_{n \geq 1} \sigma(n)q^n,
\]

where \( \sigma(n) := \sum_{d \mid n} d \). It is nearly holomorphic of weight 2 and level 1. Then

\[
E_{2,N}(z) := E_2(z) - NE_2(Nz)
\]

defines the unique Eisenstein series of weight 2 and level \( \Gamma_0(N) \); its \( T_\ell \)-eigenvalue is \( \ell + 1 \) for all primes \( \ell \neq N \) and its \( U_N \)-eigenvalue is 1. The constant term of \( E_{2,N} \) is \( \frac{N}{24} \). Let

\[
E(z) := NE_{2,N}(z) - NE_{2,N}(Nz) \in M_2(\Gamma; \mathbb{Z}_p[\zeta_N]),
\]

which has \( T_\ell \)-eigenvalue \( \ell + 1 \) for all primes \( \ell \neq N \) and \( U_N \)-eigenvalue 0. The constant term of its \( q \)-expansion at \( \infty \) is 0.

To understand congruences between these Eisenstein series and elements in \( S_2(\Gamma; \mathbb{Z}_p[\zeta_N]) \), we need to calculate the constant terms of their \( q \)-expansions at all cusps, not only \( \infty \). To do this, we make use of the Hecke action on the residue sequence (4).

Let \( T \) be the \( \mathbb{Z}_p[\zeta_N] \)-subalgebra of \( \text{End}_{\mathbb{Z}_p[\zeta_N]}(M_2(\Gamma; \mathbb{Z}_p[\zeta_N])) \) generated by \( T_\ell \) for \( \ell \nmid N \) and \( U_N \), and let \( T' \subset T \) be the subalgebra generated just by the \( T_\ell \). We consider \( \text{Div}^0(C; \mathbb{Z}_p[\zeta_N]) \) as a \( T \)-module via the action described in Proposition 2.2, so there is an exact sequence of \( T \)-modules

\[
0 \to S_2(\Gamma; \mathbb{Z}_p[\zeta_N]) \to M_2(\Gamma; \mathbb{Z}_p[\zeta_N]) \xrightarrow{\text{Res}} \text{Div}^0(C; \mathbb{Z}_p[\zeta_N]) \to 0.
\]

Let \( I \) be the ideal of \( T' \) generated by the elements \( T_\ell - \ell - 1 \) for \( \ell \neq N \) prime and \( m' = (I, p) \subset T' \), which is maximal. Write \( c := \sum_{x \in (\mathbb{Z}/N\mathbb{Z})^\times} (|x| - 0) \in \text{Div}^0(C; \mathbb{Z}_p[\zeta_N]) \).

**Proposition 2.5.** When \( N \nmid 1 \mod p \), the localization \( \text{Div}^0(C; \mathbb{Z}_p[\zeta_N]) \) is a free \( \mathbb{Z}_p[\zeta_N] \)-module of rank 2 with basis

\[
\{ \infty - 0 + c, c \}
\]

that is annihilated by \( I \). Moreover, \( U_N \), with \( U_Nc = 0 \) and \( U_N(\infty - 0 + c) = \infty - [0] + c \).

**Proof.** Set \( W = \mathbb{Z}_p[\zeta_N] \). Let \( P \) be the \( W \)-span of \( \infty - 0 + c \) and \( c \) in \( \text{Div}^0(C; W) \). The facts that \( P \) is annihilated by \( I \) and \( U_N \) acts as described follow from Proposition 2.2. Since \( N \neq 1 \mod p \), the same lemma shows that the section \( s : \text{Div}^0(C; W) \to P \) that is the identity on \( \infty - 0 \) and sends \( |x| - 0 \) to \( \frac{1}{N}c \) for \( x \in (\mathbb{Z}/N\mathbb{Z})^\times \) is \( T' \)-equivariant. Letting \( Q = k\ker s \), we have a \( T' \)-equivariant splitting \( \text{Div}^0(C; W) = P \oplus Q \).

To complete the proof, it is enough to show that \( \text{Div}^0(C; W)p[m'] = P \otimes W/p \). Indeed, this implies that \( (Q \otimes W/p)[m'] = 0 \), from which we deduce that \( (Q \otimes W/p)m' = 0 \) since \( (T'pT')m' \) is an Artin local ring, and hence \( Qm' = 0 \).

Suppose \( a = a_\infty(\infty - 0) + \sum_{x \in (\mathbb{Z}/N\mathbb{Z})^\times} a_x(|x| - 0) \in \text{Div}^0(C; W/p) \) is annihilated by \( m' \). Equivalently, \( a \) is annihilated by \( t_\ell := T_\ell - \ell - 1 \) for all primes \( \ell \neq N \). We will use the formulas from Proposition 2.2 to show this implies that \( a_x = a_1 \) for all \( x \in (\mathbb{Z}/N\mathbb{Z})^\times \). Hence we will have

\[
a = a_\infty(\infty - 0) + a_1c \in P \otimes W/p.
\]

To show that \( a_x = a_1 \) for all \( x \in (\mathbb{Z}/N\mathbb{Z})^\times \), choose a prime \( \ell \) such that \( \ell \equiv -1 \pmod{p} \) and such that \( \ell \) is a primitive root modulo \( N \). Then, since \( t_\ell a = 0 \), we have \( a_{x_\ell} = a_{\ell^{-1}x} \) for all \( x \). Since \( \ell \) is a primitive root, this implies that \( a_x = a_1 \) if \( x \) is a square, and \( a_x = a_\ell \) if \( x \) is a non-square. Now take \( q \neq -1 \pmod{p} \) to be a prime that is a not a square modulo \( N \). Then, since \( t_\ell a = 0 \), we have

\[
(q + 1)a_1 = qa_{q^{-1}} + a_q.
\]

Since \( q \) is not a square, \( a_q = a_{q^{-1}} = a_\ell \), so we have

\[
(q + 1)a_1 = (q + 1)a_\ell
\]

which implies \( a_1 = a_\ell \) because \( q \neq -1 \pmod{p} \). Hence \( a_x = a_1 \) for all \( x \in (\mathbb{Z}/N\mathbb{Z})^\times \), so \( a \) is in \( P \otimes W/p \). \( \square \)

**Corollary 2.6.** We have \( \text{Res}(E) = \frac{N^2 - 1}{24}c \) and \( \text{Res}(E_{2,N}) = \frac{N-1}{24}(\infty - [0] + c) \).
Lemma 2.7.

1. We have $S_2(\Gamma; \mathbb{Z}_p[\zeta_n])_m \neq 0$ if and only if there is a form $f \in S_2(\Gamma; \mathbb{Z}_p[\zeta_n])$ such that $a_n(f) \equiv a_n(E) \mod p$ for all $n \geq 1$.

2. We have $S_2(\Gamma; \mathbb{Z}_p[\zeta_n])_{m_\text{old}} \neq 0$ if and only if there is a form $f \in S_2(\Gamma; \mathbb{Z}_p[\zeta_n])$ such that $a_n(f) \equiv a_n(E) \mod p$ for all $n \geq 1$.

Proof. We prove (1), the proof of (2) being identical. If such a form $f$ exists, it clearly gives a non-zero element of $S_2(\Gamma; \mathbb{Z}_p[\zeta_n])_m$. Conversely, suppose that $S_2(\Gamma; \mathbb{Z}_p[\zeta_n])_m \neq 0$. Then, reducing modulo $p$, we have $S_2(\Gamma; \mathbb{Z}_p[\zeta_n])_m \neq 0$. Since $\mathbb{T}_m \otimes \mathbb{F}_p$ is Artinian, this implies that there is a non-zero element $f$ of $S_2(\Gamma; \mathbb{Z}_p[\zeta_n])_m$. Since $f$ is annihilated by $m$, we have $a_n(f) = a_n(E) \mod p$ for all $n$. We can now let $f \in S_2(\Gamma; \mathbb{Z}_p[\zeta_n])$ be any lift of $f$.

Theorem 2.8. Assume $N \not\equiv 1 \mod p$. Then $S_2(\Gamma; \mathbb{Z}_p[\zeta_n])_{m_\text{old}} = 0$ and there is a $\mathbb{T}_m$-equivariant short exact sequence

$$0 \to S_2(\Gamma; \mathbb{Z}_p[\zeta_n])_m \to M_2(\Gamma; \mathbb{Z}_p[\zeta_n])_m \xrightarrow{\text{Res}} \mathbb{Z}_p[\zeta_n] \cdot \mathfrak{c} \to 0.$$  

Moreover, $S_2(\Gamma; \mathbb{Z}_p[\zeta_n])_m = 0$ if and only if $N \equiv -1 \mod p$.

In particular, there exists $f = \sum_{n \geq 1} a_n q^n \in S_2(\Gamma; \mathbb{Z}_p[\zeta_n])$ such that $a_\ell \equiv \ell + 1 \mod p$ for all primes $\ell \neq N$ if and only if $N \equiv -1 \mod p$.

Proof. Suppose that $S_2(\Gamma; \mathbb{Z}_p[\zeta_n])_{m_\text{old}} \neq 0$. Then, by Lemma 2.7, there is an $f \in S_2(\Gamma; \mathbb{Z}_p[\zeta_n])$ with $a_n(f) \equiv a_n(E) \mod p$ for all $n \geq 1$. Since $a_0(E_2, N) \neq 0 \mod p$, this implies that there is a non-zero constant in $M_2(\Gamma; \mathbb{Z}_p[\zeta_n])$, a contradiction.

The exact sequence (7) follows directly from (6) and Proposition 2.5. If $N \equiv -1 \mod p$, then let $g \in M_2(\Gamma; \mathbb{Z}_p[\zeta_n])_m$ be such that $\text{Res}(g) = \mathfrak{c}$ and let $f = E - \frac{N^2 - 1}{24} g$. Then $f \equiv E \mod p$ and, since $\text{Res}(f) = 0$, we have $f \in S_2(\Gamma; \mathbb{Z}_p[\zeta_n])_m$.

Conversely, suppose that $N \equiv \pm 1 \mod p$ and, for the sake of contradiction, that $S_2(\Gamma; \mathbb{Z}_p[\zeta_n])_m \neq 0$. Let $E \in M_2(\Gamma; \mathbb{Z}_p[\zeta_n])$ be the reduction of $E$ modulo $p$. By Lemma 2.7, there is an $f \in S_2(\Gamma; \mathbb{Z}_p[\zeta_n])$ with $a_n(f) = a_n(E)$ for all $n \geq 1$. Since also $a_0(E) = a_0(f) = 0$, this implies that $f = E$ by the $q$-expansion principle. This implies $E \in S_2(\Gamma; \mathbb{Z}_p[\zeta_n])$, but $\text{Res}(E) \neq 0$ by Corollary 2.6, a contradiction.

For the final statement, simply note that such an $f$ must belong to $S_2(\Gamma; \mathbb{Z}_p[\zeta_n])_{m'}$, and that

$$S_2(\Gamma; \mathbb{Z}_p[\zeta_n])_{m'} = S_2(\Gamma; \mathbb{Z}_p[\zeta_n])_{m_\text{old}} \oplus S_2(\Gamma; \mathbb{Z}_p[\zeta_n])_m$$

since $m_\text{old}$ and $m$ are the only maximal ideals of $\mathbb{T}$ containing $m'$.

Let $\mathbb{T}_m^0$ be the maximal quotient of $\mathbb{T}_m$ acting faithfully on $S_2(\Gamma; \mathbb{Z}_p[\zeta_n])_m$. Recall that by duality, minimal prime ideals $\mathfrak{p}$ of $\mathbb{T}_m^0$ are in one-to-one correspondence with normalized eigenforms in $S_2(\Gamma; \overline{\mathbb{Q}}_p)$ that are congruent to $E$ modulo the unique prime above $p$ in the $p$-adic ring $\mathbb{T}_m^0 / \mathfrak{p}$. By Theorem 2.8, we know that $\mathbb{T}_m^0 \neq 0$ when $N \equiv -1 \mod p$. Moreover, we know that the eigenform corresponding to any minimal prime must be a newform because, by Mazur’s theorem, there are no oldforms that are congruent to $E$. Thus we have the following corollary, which gives Theorem B(a).

Corollary 2.9. Assume $N \equiv -1 \mod p$. Then there is a newform $f$ of weight 2 and level $\Gamma_0(N^2)$ and a prime ideal $\mathfrak{p}$ over $p$ in the ring of integers $\mathcal{O}_f$ of the Hecke field of $f$ such that $a_\ell(f) \equiv 1 + \ell \mod \mathfrak{p}$ for all primes $\ell$. 

7
3. An unramified $p$-extension of $\mathbb{Q}(N^{1/p})$ when $N \equiv -1 \mod p$

In this section we use a congruence between a cusp form and the Eisenstein series of $E$ from Corollary 2.9 to give a modular construction of a degree $p$ unramified extension of $\mathbb{Q}(N^{1/p})$ when $N \equiv -1 \mod p$, thus proving Theorem A and the second half of Theorem B. Throughout this section we assume $N \equiv -1 \mod p$.

As in Corollary 2.9, fix an eigenform $f \in S_2(\Gamma, \mathbb{Z}_p)$ that is congruent to $E$ modulo the prime $p$ lying over $p$. Let $\mathbb{Q}_p(f)/\mathbb{Q}_p$ be the field generated by the Hecke eigenvalues of $f$, $\mathcal{O}$ its ring of integers, $\varpi$ a uniformizer, and $\mathbb{F} = \mathcal{O}/\varpi$. Let $s \geq 1$ be the largest integer such that $f \equiv E \mod \varpi^s$, so $s$ is the largest integer such that $a_v(f) \equiv 1 + \ell \mod \varpi^s$ for all primes $\ell \neq N$.

We now recall a Galois-theoretic interpretation of the integer $s$. Let $\rho_f : G_{\mathbb{Q}, N_p} \to \text{GL}(V_f) \cong \text{GL}_2(\mathbb{Q}_p(f))$ the Galois representation corresponding to $f$ and let $t_f = \text{tr}(\rho_f) : G_{\mathbb{Q}, N_p} \to \mathcal{O}$ be its trace. Recall the reducibility ideal of $t_f$, as defined in [BC09, Section 1.5]: it is the smallest ideal $J \subset \mathcal{O}$ such that $t_f \equiv \psi_1 + \psi_2 \mod J$ for characters $\psi_1 : G_{\mathbb{Q}} \to (\mathcal{O}/J) \times$.

**Lemma 3.1.** The reducibility ideal of $t_f$ is $\varpi^s \mathcal{O}$.

**Proof.** Let $J \subset \mathcal{O}$ be the reducibility ideal of $t_f$ and write $t_f \equiv \psi_1 + \psi_2 \mod J$ for characters $\psi_1 : G_{\mathbb{Q}} \to (\mathcal{O}/J) \times$. Since $\det(\rho_f) = \epsilon$, we can write $\psi_1 = \psi \epsilon$ and $\psi_2 = \psi^{-1}$ for a character $\psi : G_{\mathbb{Q}, N_p} \to (\mathcal{O}/J) \times$ with $\psi \equiv 1 \mod \varpi \mathcal{O}$. In particular, $\psi$ has $p$-power order. We claim that $\psi$ is trivial. Assuming this claim, we see that $J = \varpi^t \mathcal{O}$ for the largest integer $t$ such that $t_f \equiv \epsilon + 1 \mod \varpi^t$, so $t = s$ by Cheboterov density.

It remains to show that $\psi$ is trivial. For this, note that $f$ is ordinary, since $a_p(f) \equiv a_p(E) \equiv 1 \mod \varpi \mathcal{O}$. Hence we have $t_f|I_p = \epsilon + 1$, so we see that $\psi$ is unramified at $p$. Then $\psi$ factors through the maximal unramified-outside-$N$ abelian pro-$p$ extension of $\mathbb{Q}$, which is trivial since $N \neq 1 \mod p$. Hence $\psi$ is trivial. $\Box$

The goal of this section is to prove Theorem B(b), which in turn implies Theorem A. In particular, we show the following.

**Theorem 3.2.** There is an everywhere unramified order-$p$ character $\chi : G_{\mathbb{Q}(N^{1/p})} \to (\mathcal{O}/\varpi^{s+1}) \times$ such that $t_f/G_{\mathbb{Q}(N^{1/p})} \equiv \chi \epsilon + \chi^{-1} \mod \varpi^{s+1}$.

### 3.1. Constructing an unramified $p$-extension

For a $G_{\mathbb{Q}}$-stable $\mathcal{O}$-lattice $T \subset V_f$, let $\rho_T : G_{\mathbb{Q}, N_p} \to \text{GL}(T)$ denote the corresponding representation.

**Lemma 3.3.** There is a $G_{\mathbb{Q}}$-stable lattice $T \subset V_f$ such that

$$\rho_T \mod \varpi^s = \begin{pmatrix} \epsilon & \kappa_N \\ 0 & 1 \end{pmatrix},$$

where $\kappa_N : G_{\mathbb{Q}} \to (\mathcal{O}/\varpi)^{(1)}$ is the Kummer cocycle associated to $N$. Moreover, if we write $\rho_T = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$, then the ideal generated by $c(\sigma)$ for all $\sigma \in G_{\mathbb{Q}}$ is $\varpi^s \mathcal{O}$.

**Proof.** Using Ribet’s lemma [Rib76, Proposition 2.1], we choose $T$ such that

$$\rho_T \mod \varpi = \begin{pmatrix} \omega & \tilde{b} \\ 0 & 1 \end{pmatrix},$$

where $\tilde{b} : G_{\mathbb{Q}} \to \mathbb{F}(1)$ is a cocycle with non-trivial cohomology class. Write the entries of $\rho_T$ as $\rho_T = \begin{pmatrix} a \ b \\ c \ d \end{pmatrix}$. By Lemma 3.1 and [BC09, Proposition 1.5.1, pg. 35], we see that $BC = \varpi^t \mathcal{O}$, where $B, C \subset \mathcal{O}$ are the ideals generated by $b(\sigma)$ and $c(\sigma)$, respectively, for all $\sigma \in G_{\mathbb{Q}, N_p}$. Since $\tilde{b}$ is non-trivial, we see that $B$ is the unit ideal, so $C = \varpi^s \mathcal{O}$. From this we see that $\rho_T \mod \varpi^s$ has the desired upper-triangular shape, and it remains to describe the cocycle $b$ mod $\varpi^s$.

The class of $b$ mod $\varpi^s$ belongs to

$$H^1(G_{\mathbb{Q}, N_p}, (\mathcal{O}/\varpi)^{(1)})$$

which is generated by the Kummer classes $\kappa_N$ and $\kappa_p$ of $N$ and $p$ by Kummer theory. However, the fact that $\rho_T$ is finite in the sense of Serre [Ser87] (that is, it comes from the generic fiber of a finite flat group scheme over $\mathbb{Z}_p$) forces $b$ mod $\varpi^s$ to lie in the subgroup generated by $\kappa_N$ (see [Ser87, Section 2]). Since $\tilde{b}$ is non-trivial, we see that $b$ mod $\varpi^s$ must be a unit multiple of $\kappa_N$, and we can change basis to ensure that $\rho_T \mod \varpi^s$ has the desired form. $\Box$
Fix a lattice $T \subset V_f$ as in the lemma, and let $\rho = \rho_T = \left( \begin{smallmatrix} a & b \\ c & d \end{smallmatrix} \right)$ and $\bar{b} = b \mod \varpi$. Since $\bar{b}$ is the Kummer cocycle associated to $N$, we see that $\bar{b}|G_f = 0$, where $F := \mathbb{Q}(N^{1/p})$. This implies that $b|G_F$ takes values in $\varpi \mathcal{O}$. Since we also know that $c$ takes values in $\varpi^s \mathcal{O}$, we see that the reducibility ideal (in the sense of [BC09, Section 1.5]) of $t_f|G_F$ is contained in $\varpi^{s+1}$. This implies that
\[ a|G_F \mod \varpi^{s+1} : G_F \to (\mathcal{O}/\varpi^{s+1})^\times \]
is a group homomorphism. Define a character $\chi : G_F \to (\mathcal{O}/\varpi^{s+1})^\times$ by
\[ \chi \epsilon = a|G_F \mod \varpi^{s+1}. \]
Note that, since $\det(\rho) = \epsilon$, we have $d|G_F \mod \varpi^{s+1} = \chi^{-1}$, so
\[ (8) \quad t_f|G_F = \chi \epsilon + \chi^{-1} \mod \varpi^{s+1} \]
To complete the proof of Theorem 3.2, it suffices to prove that $\chi$ has order $p$ and is unramified everywhere, which we prove in the following two propositions.

**Proposition 3.4.** The character $\chi$ is non-trivial.

**Proof.** Let $r = \rho \mod \varpi^{s+1}$. Suppose, for the sake of contradiction, that $\chi$ is trivial. Then we have
\[ r(G_F(\zeta)) \subset \left\{ \left( \begin{array}{cc} x & y \\ \varpi^s z & 1 \end{array} \right) \in \text{GL}_2(\mathcal{O}/\varpi^{s+1}) \right\}. \]
Now choose $\sigma \in G_Q$ such that $\bar{b}(\sigma) \neq 0$, and let $\tau \in G_F(\zeta)$ and write $r(\tau) = \left( \begin{array}{cc} x & y \\ \varpi^s z & 1 \end{array} \right)$. Since $x, d(\sigma) \equiv 1 \mod \varpi$, we compute that
\[ r(\sigma) \left( \begin{array}{cc} x & y \\ \varpi^s z & 1 \end{array} \right) r(\sigma)^{-1} = \left( \begin{array}{cc} * & * \\ * & 1 - b(\sigma) \det(r(\sigma))^{-1} \varpi^s \end{array} \right). \]
Since $r(G_F(\zeta))$ is normal in $r(G_Q)$, we conclude that $z b(\sigma) \det(r(\sigma))^{-1} \varpi^s = 0$. Since $b(\sigma)$ and $\det(r(\sigma))$ are units, we see that $z \in \varpi \mathcal{O}/\varpi^{s+1}$. This shows that, for any $\tau \in G_F(\zeta)$, we have $c(\tau) \equiv 0 \mod \varpi^{s+1}$.

By Lemma 3.3, we can write $c = \varpi^s \bar{c}$ for a cochain $\bar{c} : G_Q, N_p \to \mathcal{O}$ such that $\bar{c} := \bar{c} \mod \varpi$ is non-trivial. It follows that $\bar{c}$ is a cocycle $\bar{c} : G_Q \to \mathbb{F}(-1)$ with non-trivial class. Then $\bar{c}|G_Q(\zeta)$ is a homomorphism cutting out a degree-$p$ extension $K/\mathbb{Q}(\zeta_p)$ such that $\text{Gal}(\mathbb{Q}(\zeta_p)/\mathbb{Q})$ acts on $\text{Gal}(K/\mathbb{Q}(\zeta_p))$ via $\omega^{-1}$. But, since we assume that $\chi$ is trivial, the previous paragraph shows that $\bar{c}(\tau) = 0$ for all $\tau \in G_F(\zeta)$, so $K = F(\zeta_p)$. But $\text{Gal}(\mathbb{Q}(\zeta_p)/\mathbb{Q})$ acts on $\text{Gal}(F(\zeta_p)/\mathbb{Q}(\zeta_p))$ via $\omega$, so this implies $\omega = \omega^{-1}$ which is a contradiction because we assume $p > 3$. \hfill $\square$

**Proposition 3.5.** The character $\chi$ is unramified everywhere.

**Proof.** Since $\rho$ is unramified outside $Np$, $\chi$ is as well. It remains to show that $\chi$ is unramified at $N$ and $p$. We first consider ramification at $N$. By local class field theory, the maximal abelian tame quotient of the inertia group at $N$ in $G_F$ has order $N - 1$, which is prime-to-$p$ by our assumptions that $N \equiv -1 \mod p$ and $p > 2$. Since the image of $\chi$ has order $p$, this implies that $\chi$ is unramified at $N$.

Finally, to see that $\chi$ is unramified at $p$ we need to show that $\chi|I_p \cap G_F = 0$. By Lemma 3.3 and the definition of $\chi$, we can write $\chi = 1 + \alpha \varpi^s$ for an additive character $\alpha : G_F \to \mathbb{F}$, and we need to show that $\alpha|I_p \cap G_F = 0$. In this notation, (8) says
\[ t_f|G_F \equiv \epsilon + 1 + (\epsilon - 1)\alpha \varpi^s \mod \varpi^{s+1} \]
On the other hand, as we noted in the proof of Lemma 3.1, the fact that $f$ is ordinary implies that $t_f|I_p = \epsilon + 1$. Combining these two, we have $(\epsilon - 1)\alpha \varpi^s = 0$ on $I_p \cap G_F$. This is equivalent to $(\omega - 1)\alpha = 0$ as functions $I_p \cap G_F \to \mathbb{F}$. If $\sigma \in I_p \cap G_F \setminus \ker \omega$, then it follows that $\alpha(\sigma) = 0$. For $\sigma \in I_p \cap G_F \cap \ker \omega$, choose any $\tau \in I_p \cap G_F \setminus \ker \omega$. Then $\omega(\tau) \neq 1$ and $\alpha(\tau) = 0$, so we obtain
\[ 0 = (\omega(\sigma \tau) - 1)\alpha(\sigma \tau) = (\omega(\sigma)\omega(\tau) - 1)(\alpha(\sigma) + \alpha(\tau)) = (\omega(\tau) - 1)\alpha(\sigma), \]
and thus $\alpha(\sigma) = 0$. \hfill $\square$
3.2. Explicit class field theory encoded by \( f \). Keep the notation from the previous section. In particular, \( N, p, f \) are all fixed. From \( f \), there is an associated character \( \chi \) of \( G_{\mathbb{Q}(N/p)} \) as in Theorem B(b), or equivalently as defined prior to Proposition 3.5. Let \( L \) be the degree \( p \) extension of \( \mathbb{Q}(N^{1/p}) \) cut out by character \( \chi \), so \( L/\mathbb{Q}(N^{1/p}) \) is an everywhere unramified degree \( p \) extension. In this section we show how the Fourier coefficients of \( f \) (modulo \( \wp^{s+1} \)) carry information about how primes of \( \mathbb{Q}(N^{1/p}) \) split in \( L \) as well as when \( N \) is not a \( p \)-th power modulo \( \ell \) when \( \ell \equiv 1 \mod p \). This explicit information shows the advantage of our modular methods compared to Calegari’s abstract cup product argument discussed at the end of Section 1.3.

We begin by understanding how rational primes split in \( \mathbb{Q}(N^{1/p}) \). For each prime \( \ell \), fix a discrete logarithm \( \log_{\ell} : \mathbb{F}_\ell^* \to \mathbb{Z}/(\ell - 1)\mathbb{Z} \), so \( a \in \mathbb{F}_\ell^* \) is a \( p \)-th power if and only if \( \log_{\ell}(a) \equiv 0 \mod p \), which is automatic whenever \( \ell \neq 1 \mod p \).

**Lemma 3.6.** Let \( \ell \neq p, N \) be prime and let \( r \) be the multiplicative order of \( \ell \) in \( \mathbb{F}_p^* \). If \( \log_{\ell}(N) \neq 0 \mod p \), then \( \ell \) is inert in \( \mathbb{Q}(N^{1/p}) \). Otherwise, there are \( \frac{p - 1}{\ell - 1} \) primes of \( \mathbb{Q}(N^{1/p}) \) lying over \( \ell \), one with residue degree 1 and the rest having residue degree \( r \).

**Proof.** Note that the only prime factors dividing the discriminant of the order \( \mathbb{Z}[N^{1/p}] \) are \( p \) and \( N \) — the same prime divisors of the discriminant of \( \mathbb{Q}(N^{1/p}) \). Thus we can understand the splitting behavior of \( \ell \) in \( \mathbb{Q}(N^{1/p}) \) by considering how \( x^p - N \) factors over \( \mathbb{F}_\ell \).

First suppose \( \log_{\ell}(N) \neq 0 \mod p \), so \( N \) is not a \( p \)-th power in \( \mathbb{F}_\ell \). Then it is well-known that \( x^p - N \) is irreducible over \( \mathbb{F}_\ell \) (see [Lau02, Theorem VI.9.1, pg. 297], for example).

Now suppose \( \log_{\ell}(N) \equiv 0 \mod p \), so \( N = a^p \) for some \( a \in \mathbb{F}_\ell^* \). Using the substitution \( x \mapsto ay \), we get

\[
\frac{F_{\ell}[x]}{(x^p - N)} \cong \frac{F_{\ell}[y]}{(y^p - 1)} \cong F_{\ell} \times \frac{F_{\ell}[y]}{(\Phi_p(y))} \cong F_{\ell} \times F_{\ell}^{(p-1)/r},
\]

where \( \Phi_p(y) \) is the cyclotomic polynomial. For the last isomorphism, note that \( \Phi_p(y) \) divides \( y^r - y \) but \( \gcd(\Phi_p(y), y^d - y) = 1 \) for any \( d < r \), so the irreducible factors of \( \Phi_p(y) \) all have degree \( r \).

**Proposition 3.7.** Let \( \ell \neq N, p \) be prime.

1. If \( \ell \equiv 1 \mod p \) and \( a_\ell(f) \neq 2 \mod \wp^{s+1} \), then \( \log_{\ell}(N) \neq 0 \mod p \), so \( \ell \) is inert in \( \mathbb{Q}(N^{1/p}) \) and \( \ell \mathcal{O}_{\mathbb{Q}(N^{1/p})} \) splits completely in \( L \) (in fact, in the Hilbert class field of \( \mathbb{Q}(N^{1/p}) \)).

2. If \( \ell \neq 1 \mod p \), then the unique prime of \( \mathbb{Q}(N^{1/p}) \) lying over \( \ell \) of residue degree 1 splits in \( L \) if and only if \( a_\ell(f) \equiv 1 + \ell \mod \wp^{s+1} \).

**Proof.** Write the character \( \chi \) from Theorem B(b) as \( \chi = 1 + \wp^s \alpha \) with \( \alpha : G_{\mathbb{Q}(N^{1/p})} \to \mathbb{F} \) an additive character. Then \( t_\ell|G_{\mathbb{Q}(N^{1/p})} = \omega \chi + \chi^{-1} = 1 + \omega + \wp^s(\omega - 1) \alpha \). Suppose that \( \log_{\ell}(N) \equiv 0 \mod p \) so that \( \ell \) has a prime \( \lambda \) of \( \mathbb{Q}(N^{1/p}) \) lying above it of residue degree 1. Up to conjugation we may take \( \text{Frob}_\ell = \text{Frob}_\lambda \in G_{\mathbb{Q}(N^{1/p})} \).

Thus by (8), we have

\[
a_\ell(f) = t_\ell(\text{Frob}_\lambda) \equiv 1 + \ell + \wp^s(\ell - 1)\alpha(\text{Frob}_\lambda) \mod \wp^{s+1}
\]

whenever \( \log_{\ell}(N) \equiv 0 \mod p \).

When \( \ell \neq 1 \mod p \), we see that \( a_\ell(f) \equiv 1 + \ell \mod \wp^{s+1} \) if and only if \( \alpha(\text{Frob}_\lambda) = 0 \). Since \( L \) is cut out by \( \ker \chi = \ker \alpha \), it follows that \( \lambda \) splits in \( L \) if and only if \( a_\ell(f) \equiv 1 + \ell \mod \wp^{s+1}, \) proving (2).

In contrast, when \( \ell \equiv 1 \mod p \), (9) shows that \( a_\ell(f) \equiv 2 \mod \wp^{s+1} \) under the assumption \( \log_{\ell}(N) \equiv 0 \mod p \), thus establishing the contrapositive of (1). The last part of (1) follows from Lemma 3.6 and the fact that the principal ideals of \( \mathbb{Q}(N^{1/p}) \) are exactly those that split completely in its Hilbert class, which contains \( L \).

**Remark 3.8.** Note that if a prime \( \ell \) satisfies \( a_\ell(f) \equiv 1 + \ell \mod \wp^{s+1} \), then \( T_\ell \) cannot generate the Eisenstein ideal since that would force the entire Eisenstein congruence to persist modulo \( \wp^{s+1} \), contradicting the definition of \( s \). △

If we impose the hypothesis that the class number of \( \mathbb{Q}(N^{1/p}) \) is \( p \), so \( L \) is its Hilbert class field, then we can further interpret our results in a classical style suggestive of results in explicit class field theory in the case of imaginary quadratic fields. While this hypothesis on the class number is certainly not always satisfied, it holds in many examples. For instance, the hypothesis holds when \( p = 5 \) and \( N \in \{19, 29, 59, 79, 89, 109, 139, 149, 199\} \) and when \( p = 7 \) and \( N \in \{13, 41, 97, 139, 181\} \).
Corollary 3.9. Assume that $\mathbb{Q}(N^{1/p})$ has class number $p$. Let $\lambda$ be a prime of $\mathbb{Q}(N^{1/p})$ lying over $\ell \neq N, p$.

(1) Suppose that $\ell \equiv 1 \pmod{p}$ and either $\# \mathcal{O}_{\mathbb{Q}(N^{1/p})}/\mathcal{O}_L = \ell$ or $\# \mathcal{O}_{\mathbb{Q}(N^{1/p})}/\mathcal{O}_L = \ell^{p-1}$. Then the following are equivalent:

(a) $\lambda$ is a principal $\mathcal{O}_{\mathbb{Q}(N^{1/p})}$-ideal;
(b) $\lambda$ splits completely in $L$ over $\mathbb{Q}(N^{1/p})$;
(c) $\ell$ is a norm from $\mathbb{Q}(N^{1/p})$;
(d) $a_\ell(f) \equiv \ell + 1 \pmod{\mathfrak{p}^{s+1}}$.

(2) If $\ell \equiv 1 \pmod{p}$ and $a_\ell(f) \neq 2 \pmod{\mathfrak{p}^{s+1}}$, then $\ell$ is inert in $\mathbb{Q}(N^{1/p})$ and then splits in $L$. In this case $\ell$ is not a norm from $\mathbb{Q}(N^{1/p})$.

Proof. Write $F := \mathbb{Q}(N^{1/p})$, and suppose that $\ell \equiv 1 \pmod{p}$ and $\# \mathcal{O}_F/\mathcal{O}_L = \ell$. The equivalence of (a) and (b) follows from the fact that the primes that split in the Hilbert class field $L$ of $F$ are exactly the principal ideals. The equivalence of (a) and (c) follows from the fact that the norm of an element is equal to the norm of the ideal it generates. The equivalence of (b) and (d) follows from the first part of Proposition 3.7.

The second part follows from Proposition 3.7 and the fact that $L$ is the Hilbert class field of $F$ by assumption.

Example 3.10. We finish with an example when $p = 5$ and $N = 19$. We compute that $\mathbb{Q}(19^{1/5})$ has class number 5, so Corollary 3.9 applies. In this case $f$ has LMFDB label 361.2.a.f and Hecke field $\mathbb{Q}(\sqrt{5})$. The Eisenstein congruence holds modulo $\mathfrak{p} = \sqrt{5}$, but not modulo $\mathfrak{p}^2 = 5$, so $s = 1$ in this case. Set $\beta = \frac{1+\sqrt{5}}{2}$. Table 1 contains the first sixty prime-index coefficients for $f$. The ones in bold are those for which the Eisenstein congruence persists modulo 5, and the circled primes $\ell$ are those for which Corollary 3.9 implies that there exists a principal prime ideal of $F$ lying over $\ell$. (We also circle 19 since the principal ideal generated by $19^{1/5}$ clearly lies over it.) Moreover, in this example we can calculate that $\mathcal{O}_F = \mathbb{Z}[19^{1/5}]$ and hence it is easy to write the norm form explicitly. In particular, the four equivalent conditions on $\ell$ in Corollary 3.9(1) are also equivalent to

$$\ell = a^5 - 95a^3b - 95a^3cd + 95a^2b^2d + 95a^2bc^2 + 180ab^2e^2 + 180a^2d^2e - 95ab^5 + 180ab^2e^2 - 1805abde - 1805abd^3 - 1805ac^3e + 1805ac^2d^2 - 34295ade^3 + 19b^5 - 1805b^3de + 1805b^2c^2d - 1805bc^3d - 34295be^3 + 34295bd^2e^2 + 361e^5 + 34295c^2de^2 - 34295cdc^3e + 6859b^5 + 130321e^5$$

for some $(a, b, c, d, e) \in \mathbb{Z}^5$. \[\triangle\]
