Generalized Greatest Common Divisors, Divisibility Sequences, and Vojta’s Conjecture for Blowups

JOSEPH H. SILVERMAN

Abstract. We apply Vojta’s conjecture to blowups and deduce a number of deep statements regarding (generalized) greatest common divisors on varieties, in particular on projective space and on abelian varieties. Special cases of these statements generalize earlier results and conjectures. We also discuss the relationship between generalized greatest common divisors and the divisibility sequences attached to algebraic groups, and we apply Vojta’s conjecture to obtain a strong bound on the divisibility sequences attached to abelian varieties of dimension at least two.

Introduction

Bugeaud, Corvaja, and Zannier [2] recently proved that if \( a \) and \( b \) are multiplicatively independent integers, then for every \( \epsilon > 0 \) there is a constant \( N = N(a, b, \epsilon) \) so that
\[
\gcd(a^n - 1, b^n - 1) \leq 2^n \epsilon^n \quad \text{for all } n \geq N. \tag{1}
\]
The proof of this beautiful, but innocuous looking, inequality requires an ingenious application of Schmidt’s Subspace Theorem [14]. Corvaja and Zannier [4, Proposition 4] generalize (1) by replacing \( a^n \) and \( b^n \) with arbitrary elements from a fixed finitely generated subgroup of \( \overline{\mathbb{Q}}^* \).

For ease of exposition, we state their result over \( \mathbb{Q} \).

Theorem 1 (Corvaja-Zannier [4]). Let \( S \) be a finite set of rational primes and let \( \epsilon > 0 \). There is a finite set \( Z = Z(S, \epsilon) \subset \mathbb{Z}^2 \) so that all \( \alpha, \beta \in \mathbb{Z}_S^* \cap \mathbb{Z} \) satisfy one of the following three conditions:

1. \( (\alpha, \beta) \in Z \).
2. \( \alpha^m = \beta^n \) for some \((m, n)\) satisfying \( 1 \leq \max\{m, n\} \leq \epsilon^{-1} \).
3. \( \gcd(\alpha - 1, \beta - 1) \leq \max\{|\alpha|, |\beta|\}^{\epsilon} \).

Key words and phrases. greatest common divisor, divisibility sequence, algebraic group, Vojta conjecture.

The author’s research supported by NSA grant H98230-04-1-0064.
In other words, if $\alpha, \beta \in \mathbb{Z}$ are $S$-units, then
\[ \gcd(\alpha - 1, \beta - 1) \leq \max(|\alpha|, |\beta|) \]
except for some obvious families of exceptions together with a finite number of additional exceptions. Analogous statements for elliptic curves and/or over function fields have been studied by a number of authors [1, 13, 18, 19].

The purpose of this note is to explain how Vojta’s Conjecture [23, Conjecture 3.4.3] applied to varieties blown up along smooth subvarieties leads to a very general statement about greatest common divisors that encompasses many known results and previous conjectures. Thus although we do not prove unconditional results in this paper, we hope that the application of Vojta’s conjecture will help to put the problem of gcd bounds into a general context, while at the same time suggesting precise statements whose proofs may be possible using current techniques from Diophantine approximation and arithmetic geometry. (See also McKinnon’s paper [13] for a discussion of Vojta’s conjecture applied to certain blowups.)

We begin in the Section 1 by describing three special cases of our main theorem. These serve to motivate our general result and to justify the notation that is needed later. We next in Section 2 set notation and explain how a generalized concept of greatest common divisor is naturally formulated in terms of the height of points on blowup varieties with respect to the exceptional divisor of the blowup. Section 3 states Vojta’s conjecture, followed in Section 4 by our main result (Theorem 6) in which we apply Vojta’s conjecture to a blowup variety, making use of the well-known relation between the canonical bundle on a variety and on its blowup. In Section 5 we apply our main theorem to prove the three special cases from Section 1, including some additional arguments to pin down the exceptional sets more precisely. Section 6 takes up the question of divisibility sequences, which are sequences $(a_n)_{n \geq 1}$ satisfying $m|n \Rightarrow a_m|a_n$. We are especially interested in divisibility sequences associated to algebraic groups, or more precisely, to group schemes over $\mathbb{Z}$. We show that these geometric divisibility sequences are closely related to generalized greatest common divisors and apply Vojta’s conjecture to the divisibility sequences attached to abelian varieties of dimension at least 2. Finally, in Section 7, we make a few final remarks and pose some questions.

Acknowledgements. I would like to thank Y. Bugeaud, P. Corvaja, D. McKinnon, Z. Rudnick, G. Walsh, and U. Zannier, for their helpful email correspondence during the preparation of this article, and D.
In this section we describe three special cases of our main theorem. These generalize earlier results and conjectures appearing in the literature. In order to avoid excessive notation, we restrict ourselves to working over $\mathbb{Q}$. All results are conditional on the validity of Vojta’s conjecture. We refer the reader to Section 3 (Conjecture 5) or to Vojta’s original monograph [23, Conjecture 3.4.3] for the statement of Vojta’s conjecture. In order to state our first result, we need one piece of notation.

**Definition 1.** Let $S$ be a finite set of rational primes. For any nonzero integer $x \in \mathbb{Z}$, we write $|x|_S'$ for the largest divisor of $x$ that is not divisible by any of the primes in $S$, i.e.

$$|x|_S' = |x| \prod_{p \in S} |x|_p.$$ 

Informally, we call $|x|_S'$ the “prime-to-$S$” part of $x$. In particular, $x$ is an $S$-unit if and only if $|x|_S' = 1$.

Our first result deals with $\mathbb{P}^n$ blown up along a smooth subvariety.

**Theorem 2.** Fix a finite set of rational primes $S$. Let $f_1, f_2, \ldots, f_t \in \mathbb{Z}[X_0, \ldots, X_n]$ be homogeneous polynomials so that the set of zeros

$$V = \{f_1 = f_2 = \cdots = f_t = 0\} \subset \mathbb{P}^n$$

is a smooth variety, and assume further that $V$ does not intersect the union of the coordinate hyperplanes $\bigcup_{i=0}^n \{X_i = 0\}$. Let $r = n - \dim(V) \geq 2$ be the codimension of $V$ in $\mathbb{P}^n$.

Assume that Vojta’s conjecture is true (for $\mathbb{P}^n$ blown up along $V$). Fix $\epsilon > 0$. Then there is a homogeneous polynomial $0 \neq g \in \mathbb{Z}[X_0, \ldots, X_n]$, depending on $f_1, \ldots, f_t$ and $\epsilon$, and a constant $\delta$, depending on $f_1, \ldots, f_t$, so that every $\mathbf{x} = (x_0, x_1, \ldots, x_n) \in \mathbb{Z}^{n+1}$ with $\gcd(x_0, \ldots, x_n) = 1$ satisfies either

1. $g(\mathbf{x}) = 0$, or
2. $\gcd(f_1(\mathbf{x}), \ldots, f_t(\mathbf{x}))$

$$\leq \max\{|x_0|, \ldots, |x_n|\}^\epsilon \cdot (|x_0x_1 \cdots x_n|_S')^{1/(r-1+\delta\epsilon)}.$$ 

**Example 1.** We apply Theorem 2 to $\mathbb{P}^2$ with $f_1 = X_1 - X_0$ and $f_2 = X_2 - X_0$. Then $V$ is a single point and $r = 2$, so the theorem says that off of a one dimensional exceptional set we have

$$\gcd(x_1 - x_0, x_2 - x_0) \leq \max\{|x_0|, |x_1|, |x_2|\}^\epsilon \cdot (|x_0x_1x_2|_S')^{1/(1+\delta\epsilon)}.$$
In particular, suppose that we take \( x_0 = 1 \) and restrict \( x_1 \) and \( x_2 \) to be \( S \)-units, as in Theorem 1. Then \( |x_0 x_1 x_2|_S = 1 \), so (2) becomes

\[
\gcd(x_1 - 1, x_2 - 1) \leq \max\{|x_1|, |x_2|\}^\epsilon
\]

and we recover the inequality of Theorem 1. (Theorem 1 also includes a description of the exceptional set, but once one knows that the exceptional set is a union of curves, it is not hard to recover this description.) Thus Vojta’s conjecture implies a natural generalization of Theorem 1 in which we remove the restriction that \( \alpha \) and \( \beta \) be \( S \)-units and replace condition (3) of Theorem 1 with the inequality (3) of Theorem 1 with the inequality

\[
\gcd(\alpha - 1, \beta - 1) \leq \max\{|\alpha|, |\beta|\}^\epsilon \cdot (|\alpha\beta|_S^{1/1+\delta})^\epsilon. \tag{3}
\]

It would be quite interesting to give an unconditional proof of this generalization. We also remark that a closer analysis of this special case of Theorem 2 shows that (3) should be valid for any \( \delta < 1 \).

Our second example deals with elliptic curves and has applications to the theory of elliptic divisibility sequences.

**Theorem 3.** Let \( E/Q \) be an elliptic curve given by a Weierstrass equation, and for any nonzero point \( P = (x_P, y_P) \in E(Q) \), write \( x_P = A_P/D_P^2 \) as a fraction in lowest terms with \( D_P > 0 \). Also let \( H(P) = H(x_P) = \max\{|A_P|, |D_P^2|\} \) be the usual Weil height on \( E \).

Assume that Vojta’s conjecture is true (for \( E^2 \) blown up at \((O, O)\)). Then for every \( \epsilon > 0 \) there is a proper closed subvariety \( Z = Z_\varepsilon(E) \subset E^2 \) so that

\[
\gcd(D_P, D_Q) \leq (H(P) \cdot H(Q))^\epsilon \quad \text{for all } (P, Q) \in E^2(Q) \setminus Z.
\]

The exceptional set \( Z \) consists of a finite number of translates of proper algebraic subgroups of \( E^2 \). If \( E \) does not have CM, then we can say more precisely \( Z \) is a finite union of translates of the subgroups

\[
\{(mT, nT) \in E^2 : T \in E\} \quad \text{with } (m, n) \in \mathbb{Z}^2 \text{ satisfying } m^2 + n^2 \leq \frac{1}{2\epsilon}.
\]

(A similar statement holds if \( E \) has CM, with \( m \) and \( n \) replaced by more general isogenies.)

**Example 2.** Let \( E/Q \) be an elliptic curve and \( P \in E(Q) \) a point of infinite order. With notation as in Theorem 3, the elliptic divisibility sequence (EDS) associated to \( P \) is the sequence of integers \((D_{nP})_{n \geq 1}\). (For further information about elliptic divisibility sequences, including a not-quite-equivalent alternative definition, see [5, 6, 7, 13, 15, 19, 20, 21, 22, 24, 25].) These sequences have the property that if \( m|n \), then \( D_{mP} | D_{nP} \), whence their name. Now let \( P \) and \( Q \) be independent
points in \( E(\mathbb{Q}) \). Then Theorem 3 implies that there is a constant \( C = C_\epsilon(E, P, Q) \) so that
\[
\gcd(D_{mP}, D_{nQ}) \leq C \max\{D_{mP}, D_{nQ}\}^\epsilon \quad \text{for all } m, n \geq 1.
\]
(Note that since \( P \) and \( Q \) are independent, there are only finitely many multiples \( mP, nQ \) that lie on any fixed curve in \( E^2 \). We are also using Siegel’s theorem [16, IX.3.3], which says that \( 2 \log D_{nP} \sim h(nP) \) as \( n \to \infty \).)

Our final example is the amusing observation that Vojta’s conjecture allows us to mix greatest common divisors of a multiplicative group with an elliptic curve. The following result, although far from the most general, gives a flavor of what is can be proven. Again, an unconditional proof would be quite interesting.

**Theorem 4.** Let \( E/\mathbb{Q} \) be an elliptic curve and let \( S \) be a finite set of rational primes. Assume that Vojta’s conjecture is true for \( E \times \mathbb{P}^1 \) blown up at \((O, 1)\). Then for every \( \epsilon > 0 \) there is a constant \( C = C(E, S, \epsilon) \) so that
\[
\gcd(D_Q, b - 1) \leq C \cdot \max\{D_Q, b\}^\epsilon \quad \text{for all } Q \in E(\mathbb{Q}) \text{ and } b \in \mathbb{Z}_S^* \cap \mathbb{Z}.
\]
(By convention, we define the greatest common divisor of two rational numbers to be the greatest common divisor of their numerators.) In particular, if \( P \in E(\mathbb{Q}) \) is a point of infinite order and if \( a \geq 2 \) is an integer, then
\[
\gcd(D_{nP}, a^m - 1) \leq \max\{D_{nP}, a^m\}^\epsilon
\]
provided that \( \max\{m, n\} \) is sufficiently large.

### 2. Generalized gcds and blowups

We set the following notation, which will remain fixed throughout this paper. For definitions and normalizations related to absolute values and heights, see [11, Part B] or [12, Chapters 2, 3].

- \( k \) a number field.
- \( M_k \) a complete set of absolute values on \( k \). For \( v \in M_k \), we define \( v^+(\alpha) = \max\{v(\alpha), 0\} \), and we assume that the absolute values are normalized so that \( h(\alpha) = \sum_{v \in M_k} v^+(\alpha) \) is the absolute logarithmic Weil height of \( \alpha \). We denote by \( M_k^0 \), respectively by \( M_k^\infty \), the set of nonarchimedean, respectively archimedean, places in \( M_k \).
- \( S \) a finite set of places of \( k \), including all of the archimedean places.
- \( X/k \) a smooth projective variety defined over \( k \).
\( h_{X,D} \) an absolute logarithmic Weil height on \( X \) with respect to the divisor \( D \).

\( \lambda_{X,D} \) an absolute logarithmic local height on \( X \) with respect to the divisor \( D \).

Let \( a, b \in \mathbb{Z} \). The greatest common divisor of \( a \) and \( b \) is given by the formula

\[
\log \gcd(a, b) = \sum_{\text{prime } p} \min\{\operatorname{ord}_p(a), \operatorname{ord}_p(b)\} \log p
\]

\[
= \sum_{v \in M_k^0} \min\{v(\alpha), v(\beta)\}.
\]

If \( a \) and \( b \) are rational numbers, rather than integers, then we can compute the gcd of their numerators by using \( v^+ \) in place of \( v \), and having done this, there is no reason to restrict ourselves to the nonarchimedean places. Moving from \( \mathbb{Q} \) to the number field \( k \), we follow [4] and define the generalized (logarithmic) greatest common divisor of \( \alpha, \beta \in k \) to be the quantity

\[
h_{\gcd}(\alpha, \beta) = \sum_{v \in M_k} \min\{v^+(\alpha), v^+(\beta)\}.
\]

In particular, if \( \alpha, \beta \in \mathbb{Z} \), then \( h_{\gcd}(\alpha, \beta) = \log \gcd(\alpha, \beta) \).

A fancier way to view the function

\[
v^+: k \longrightarrow [0, \infty]
\]

is as the local height function on \( \mathbb{P}^1(k) \) with respect to the divisor \( (0) \), where we identify \( k \cup \{\infty\} \) with \( \mathbb{P}^1(k) \) and set \( v^+(\infty) = 0 \). We would like to find a similar height theoretic interpretation for the function

\[
G : \mathbb{P}^1(k) \times \mathbb{P}^1(k) \longrightarrow [0, \infty], \quad (\alpha, \beta) \longmapsto \min\{v^+(\alpha), v^+(\beta)\},
\]

that appears in the definition of the generalized greater common divisor. Intuitively, \( G(\alpha, \beta) \) is large if and only if the point \( (\alpha, \beta) \) is \( v \)-adically close to the point \( (0, 0) \). This resembles the intuitive characterization of a local height function,

\[
\lambda_{X,D}(P, v) = -\log(v\text{-adic distance from } P \text{ to } D),
\]

except that \((0, 0)\) is not a divisor on \((\mathbb{P}^1)^2\). However, there is a general theory that associates a local height function \( \lambda_{X,Y}(P, v) \) to any subvariety \( Y \) of \( X \), or more generally to any closed subscheme \( Y \), see [17] or [23, §5]. For our purposes, it is convenient to use an equivalent formulation in terms of blowups.

Continuing with our example, let \( X = (\mathbb{P}^1)^2 \), let \( \pi : \tilde{X} \rightarrow X \) be the blowup of \( X \) at the point \((0, 0)\), and let \( E = \pi^{-1}(0, 0) \) be the
exceptional divisor of the blowup. Then it is an easy exercise using explicit equations (or see [23, Lemma 2.5.2]) to verify that a local height function on $\tilde{X}$ for the divisor $E$ is given by the formula

$$\lambda_{\tilde{X},E}(\pi^{-1}(\alpha, \beta), v) = \min\{v^+(\alpha), v^+(\beta)\}$$

for all $(\alpha, \beta) \in X(k) \setminus (0, 0)$.

Adding these local heights gives the global formula

$$h_{\gcd}(\alpha, \beta) = \sum_{v \in M_k} \lambda_{\tilde{X},E}(\pi^{-1}(\alpha, \beta), v) = h_{\tilde{X},E}(\pi^{-1}(\alpha, \beta)).$$

In other words, the (generalized) logarithmic gcd of $\alpha$ and $\beta$ is equal to the Weil height of $(\alpha, \beta)$ on a blowup of $\mathbb{P}^1\times \mathbb{P}^1$ with respect to the exceptional divisor of the blowup. This identification allows us to bring the machinery of heights to bear on problems concerning greatest common divisors, and in particular allows us to apply Vojta’s conjecture to such problems.

Having identified $h_{\gcd}(\alpha, \beta)$ with the Weil height on a particular blowup, it is natural to generalize the notion of greatest common divisor to arbitrary varieties blown up up along arbitrary subvarieties.

**Definition 2.** Let $X/k$ be a smooth variety and let $Y/k \subset X/k$ be a subvariety of codimension $r \geq 2$. Let $\pi : \tilde{X} \to X$ be the blowup of $X$ along $Y$, and let $\tilde{Y} = \pi^{-1}(Y)$ be the exceptional divisor of the blowup.

For $P \in X \setminus Y$, we let $\tilde{P} = \pi^{-1}(P) \in \tilde{X}$.

The **generalized (logarithmic) greatest common divisor** of the point $P \in (X \setminus Y)(k)$ with respect to $Y$ is the quantity

$$h_{\gcd}(P; Y) = h_{\tilde{X},\tilde{Y}}(\tilde{P}).$$

**Example 3.** Let $X = \mathbb{P}^n$ and let $Y = [1, 0, 0, \ldots, 0]$. For $x \in \mathbb{P}^n(\mathbb{Q})$, choose homogeneous coordinates $x = [x_0, x_1, \ldots, x_n]$ with $x_i \in \mathbb{Z}$ and $\gcd(x_0, \ldots, x_n) = 1$. Then

$$h_{\gcd}(x; Y) = \log \gcd(x_1, x_2, \ldots, x_n) + O(1)$$

for $x = [x_0, x_1, \ldots, x_n] \in \mathbb{P}^n(\mathbb{Q})$.

**Example 4.** Again let $X = \mathbb{P}^n$ and let $Y$ be a subvariety of codimension $r \geq 2$ defined by the vanishing of a collection of homogeneous polynomials $f_1, f_2, \ldots, f_t \in \mathbb{Z}[X_0, \ldots, X_n]$. Then for all points $x = [x_0, x_1, \ldots, x_n] \in \mathbb{P}^n(\mathbb{Q})$ written with normalized homogeneous coordinates as in Example 3, we have

$$h_{\gcd}(x; Y) = \log \gcd(f_1(x), \ldots, f_t(x)) + O(1).$$
Compare the righthand side of this formula with the lefthand side of condition (2) in Theorem 2. This will allow us to reformulate Theorem 2 in terms of heights on blown up varieties and thence to apply Vojta’s conjecture.

**Example 5.** Let \( E/\mathbb{Q} \) be an elliptic curve given by a (minimal) Weierstrass equation, let \( X = E^2 \), let \( Y = \{(O, O)\} \), and let \( \pi_1, \pi_2 : X \to E \) denote the two projections. The square of the ideal sheaf \( \mathcal{I}_Y \) of \( Y \) is generated locally by the two functions \( \pi_1^*(x^{-1}) \) and \( \pi_2^*(x^{-1}) \),

\[
\mathcal{I}_Y^2 = \pi_1^*(x^{-1})\mathcal{O}_{X,Y} + \pi_2^*(x^{-1})\mathcal{O}_{X,Y}.
\]

Hence the greatest common divisor of a point \( (P, Q) \in X(\mathbb{Q}) \) with respect to \( Y = \{(O, O)\} \) is given by

\[
h_{\gcd}((P, Q); Y) = \sum_{v \in \mathcal{M}_Q} \frac{1}{2} \min\{v^+(x_P^{-1}), v^+(x_Q^{-1})\}
\]

\[
= \log \gcd(D_P, D_Q), \tag{4}
\]

where recall (cf. Theorem 3) that for \( P \in E(\mathbb{Q}) \), we write \( x_P = A_P/D_P^2 \).

### 3. Vojta’s Conjecture

We recall the statement of Vojta’s conjecture [23, Conjecture 3.4.3].

**Conjecture 5** (Vojta [23]). Set the following notation:

- \( k \) a number field.
- \( S \) a finite set of places of \( k \).
- \( X/k \) a smooth projective variety.
- \( A \) an ample divisor on \( X \).
- \( K_X \) a canonical divisor on \( X \).

Then for every \( \epsilon > 0 \) there exists a proper Zariski-closed subset \( Z = Z(\epsilon, X, A, D, k, S) \) of \( X \) and a constant \( C_\epsilon = C_\epsilon(X, A, D, k, S) \) so that

\[
\sum_{v \in S} \lambda_{X,D}(P, v) + h_{X,K_X}(P) \leq \epsilon h_{X,A}(P) + C_\epsilon
\]

for all \( P \in X(k) \setminus Z \). \( \tag{5} \)

**Remark 1.** Vojta’s conjecture contains the additional statement that aside from a set of dimension zero, the set \( Z \) may be chosen independently of the field \( k \) and the set of places \( S \). In other words, there is a set \( Z_0 = Z_0(\epsilon, X, A, D) \) so that for any finite extension \( k'/k \) and any finite set of places \( S' \) of \( k' \), there is a finite set of points \( Z_1 = Z_1(\epsilon, X, A, D, k', S') \) so that (5) holds for all \( P \in X(k') \) with \( P \notin Z = Z_0 \cup Z_1 \). We will be working over a single number field, so we will not need this stronger version.
Remark 2. In Vojta’s conjecture and throughout this paper, when we say that a constant depends on a divisor $D$ on a variety $X$, we assume that both global and local heights $h_{X,D}$ and $\lambda_{X,D}$ have been chosen and that the constant in question may depend on this choice.

Definition 3. With notation as in the statement of Conjecture 5, we let
\[
h_{X,D,S}(P) = \sum_{v \in S} \lambda_{X,D}(P,v),
\]
\[
h'_{X,D,S}(P) = \sum_{v \notin S} \lambda_{X,D}(P,v).
\]

This corresponds to Vojta’s notation [23] via $m_S(D,P) = h_{X,D,S}(P)$ and $N_S(D,P) = h'_{X,D,S}(P)$. Making an analogy with Nevanlinna theory, Vojta calls $m_S(D,P)$ the “proximity function” and $N_S(D,P)$ the “counting function.” Then Vojta’s fundamental inequality (5) becomes the succinct statement
\[
h_{X,D,S}(P) + h_{X,K_X}(P) \leq \epsilon h_{X,A}(P) + C_\epsilon \quad \text{for all } P \in X(k) \setminus Z.
\] (6)

4. Applying Vojta’s conjecture to blowups

Let $X/k$ be a smooth variety and let $Y/k \subset X/k$ be a smooth subvariety of codimension $r \geq 2$. Let $\pi : \tilde{X} \to X$ be the blowup of $X$ along $Y$, and let $\tilde{Y} = \pi^{-1}(Y)$ be the exceptional divisor of the blowup. For $P \in X \setminus Y$, we let $\tilde{P} = \pi^{-1}(P) \in \tilde{X}$. A nice property of blowups of smooth varieties along smooth subvarieties is that it is easy to describe the canonical bundle on the blowup [10, Exercise II.8.5],
\[
K_{\tilde{X}} \sim \pi^*K_X + (r-1)\tilde{Y}.
\]
(Here $\sim$ denotes linear equivalence.) We also observe that if $A$ is an ample divisor on $X$, then there exists an integer $N$ so that $-\tilde{Y} + N\pi^*A$ is ample on $\tilde{X}$. This follows from the Nakai-Moishezon Criterion [10, Theorem A.5.1]. We choose such an $N$ and let
\[
\tilde{A} = -\frac{1}{N}\tilde{Y} + \pi^*A \in \text{Div}(\tilde{X}) \otimes \mathbb{Q},
\]
so $\tilde{A}$ is in the ample cone of $\tilde{X}$.

We make the following assumption:

\begin{align*}
\text{The anticanonical divisor } -K_X \text{ is a normal crossings divisor and } \text{Support}(K_X) \cap Y &= \emptyset.
\end{align*}

(7)
(In practice, it suffices to assume that some multiple of $-K_X$ is a normal crossings divisor. The case $K_X = 0$ is also permitted.) With
notation as above and under the assumption (7), we apply Vojta’s conjecture to the variety $\tilde{X}$ and the divisor $D = -\pi^*K_X$ to obtain the inequality

$$h_{\tilde{X},-\pi^*K_X,S}(\tilde{P}) + h_{\tilde{X},K_X}(\tilde{P}) \leq \epsilon h_{\tilde{X},A}(\tilde{P}) + C_\epsilon$$

for all $\tilde{P} \in \tilde{X}(k) \setminus \tilde{Z}$.

Substituting $K_{\tilde{X}} = \pi^*K_X + (r - 1)\tilde{Y}$ and $\tilde{A} = \frac{1}{N}Y + \pi^*A$

and using functorial properties of height functions, we obtain

$$-h_{X,K_X,S}(P) + h_{X,K_X}(P) + (r - 1)h_{\tilde{X},\tilde{Y}}(\tilde{P})$$

$$\leq \epsilon h_{X,A}(P) - \frac{\epsilon}{N} h_{X,\tilde{Y}}(\tilde{P}) + C_\epsilon$$

for all $P \in X(k) \setminus Z$,

where we have written $Z = \pi(\tilde{Z})$. The two leftmost terms may be combined using $h_{X,D,S} + h'_{X,D,S} = h_{X,D}$, which yields

$$h'_{X,K_X,S}(P) + \left(r - 1 + \frac{\epsilon}{N}\right) h_{\tilde{X},\tilde{Y}}(\tilde{P}) \leq \epsilon h_{X,A}(P) + C_\epsilon$$

for all $P \in X(k) \setminus Z$.

Finally, a small amount of algebra, the definition $h_{\gcd}(P;Y) = h_{\tilde{X},\tilde{Y}}(\tilde{P})$, and setting $\delta = \epsilon/N$ gives the following result, where for the convenience of the reader we restate all of our assumptions.

**Theorem 6.** Let $X/k$ be a smooth variety, let $A$ be an ample divisor on $X$, and let $Y/k \subset X/k$ be a smooth subvariety of codimension $r \geq 2$.

Assume that $-K_X$ is a normal crossings divisor whose support does not intersect $Y$. Assume further that Vojta’s conjecture is true (at least for the blowup $\pi : \tilde{X} \to X$ of $X$ along $Y$ and for the divisor $D = -\pi^*K_X$).

Then for every finite set of places $S$ and every $0 < \epsilon < r - 1$ there is a proper closed subvariety $Z = Z(\epsilon, X, Y, A, k, S) \subset X$, a constant $C_\epsilon = C_\epsilon(X, Y, A, k, S)$, and a constant $\delta = \delta(X, Y, A)$ so that

$$h_{\gcd}(P; Y) \leq \epsilon h_{X,A}(P) + \frac{1}{r - 1 + \delta \epsilon} h'_{X, -\pi^*K_X,S}(P) + C_\epsilon$$

for all $P \in X(k) \setminus Z$. (8)

5. **Proofs of Theorems 2, 3, and 4**

In this section we show how our main result (Theorem 6) can be used to prove the three special cases stated in Section 1.
Proof of Theorem 2. We apply Theorem 6 to the following data:

\[ X = \mathbb{P}^n, \]
\[ Y = \{f_1 = f_2 = \cdots = f_t = 0\} \subset \mathbb{P}^n, \]
\[ K_X = -\sum_{i=0}^{n} H_i, \quad \text{where} \quad H_i = \{X_i = 0\} \in \text{Div}(\mathbb{P}^n), \]
\[ A = H_0. \]

Notice that \(-K_X\) is a normal crossings divisor and that \(Y\) is disjoint from the support of \(-K_X\) by assumption. For \(P \in \mathbb{P}^n(\mathbb{Q})\), let \(x = (x_0, \ldots, x_n) \in \mathbb{Z}^{n+1}\) with \(\gcd(x_i) = 1\) be normalized homogeneous coordinates for \(P\). Then by definition of the Weil height we have

\[ h_{X,A} = \log \max\{|x_0|, \ldots, |x_n|\}, \quad (9) \]

and Example 4 says that

\[ h_{\gcd}(P; Y) = \log \gcd(f_1(x), \ldots, f_t(x)). \quad (10) \]

(All height equalities up to \(O(1)\).) Further, by definition of the \(S\)-part of the height, we have

\[ h'_{X,H_i,S}(P) = \sum_{v \in S} a^+(x_i) = \log |x_i|_S', \]

so

\[ h'_{X,-K_X,S}(P) = \sum_{i=0}^{n} h'_{X,H_i,S}(P) = \log |x_0 x_1 \cdots x_n|_S'. \quad (11) \]

We now substitute (9), (10) and (11) into the inequality (8) of Theorem 6 to obtain

\[ \log \gcd(f_1(x), \ldots, f_t(x)) \leq \epsilon \log \max\{|x_0|, \ldots, |x_n|\} + \frac{1}{r - 1 + \delta \epsilon} \log |x_0 x_1 \cdots x_n|_S' + C \epsilon \]

for all \(P = [x] \in \mathbb{P}^n(\mathbb{Q}) \setminus Z\).

Exponentiating this inequality completes the proof of Theorem 2, once we observe that the exceptional set \(Z\) is contained in some hypersurface, so may be replaced by the zero set of a single nonzero polynomial. \(\Box\)

Proof of Theorem 3. Let \(\pi_1, \pi_2 : E \times E \to E\) be the two projections. We apply Theorem 6 to the following data:

\[ X = E \times E, \quad Y = \{(O, O)\}, \quad K_X = 0, \quad A = \pi_1^*(O) + \pi_2^*(O). \]
We compute
\[ h_{X,A}(P, Q) = h_{E \times E, \pi_1^*(O) + \pi_2^*(O)}(P, Q) \]
\[ = h_{E,O}(P) + h_{E,O}(Q) + O(1) \]
\[ = h_{E,O}'(P) + h_{E,O}'(Q) + O(1) \]
\[ = \text{definition of } X \text{ and } A, \]
\[ \text{functoriality of heights.} \]
\[ (12) \]

Next we recall from (4) in Example 5 that the generalized greatest common divisor of \((P, Q)\) with respect to \((O, O)\) is given by
\[ \log \gcd(D_P, D_Q) = \log \gcd((P, Q); (O, O)). \]
\[ (13) \]

Substituting (12) and (13) into inequality (8) of Theorem 6 yields (note \(K_X = 0\), so the \(h_{X,-K_x,S}'\) term disappears)
\[ \log \gcd(D_P, D_Q) \leq \epsilon \left( h_{E,O}(P) + h_{E,O}(Q) \right) + C_\epsilon \]
\[ \text{for all } (P, Q) \in E^2(Q) \setminus Z. \]

Exponentiating gives the first part of Theorem 3.

It remains to describe the exceptional set \(Z\). Let \(\Gamma \subset Z\) be an irreducible component of \(Z\) such that
\[ \log \gcd(D_P, D_Q) \geq \epsilon \left( h(P) + h(Q) \right) + C_\epsilon \]
\[ \text{for infinitely many } (P, Q) \in \Gamma(Q), \]
\[ (14) \]
where to ease notation we let \(h(P) = h_{E,O}(P)\). Faltings’ theorem \([9]\) tells us that \(\Gamma\) is a translate of an abelian subvariety of \(E^2\), i.e. \(\Gamma\) is a translate of an elliptic curve. If \(E\) does not have CM, then the abelian subvarieties of \(E^2\) are precisely the curves
\[ \Gamma_{n_1,n_2} = \{(n_1T, n_2T) : T \in E\} \text{ for } n_1, n_2 \geq 0 \text{ with } \gcd(n_1, n_2) = 1. \]

Thus the assumption that \(\Gamma\) contains infinitely many points satisfying (14) implies that there is a fixed pair of integers \((n_1, n_2)\) as above and a fixed pair of points \((R_1, R_2) \in E^2(Q)\) so that
\[ \Gamma = \Gamma_{n_1,n_2} + (R_1, R_2) = \{(n_1T + R_1, n_2T + R_2) : T \in E\}. \]

Hence
\[ \log \gcd(D_{n_1T+R_1}, D_{n_2T+R_2}) \geq \epsilon \left( h(n_1T + R_1) + h(n_2T + R_2) \right) + O(1) \]
\[ = \epsilon (n_1^2 + n_2^2) h(T) + O \left( \sqrt{h(T)} \right) \]
\[ \text{for infinitely many } T \in E(Q). \]
\[ (15) \]

Here the big-\(O\) constant may depend on \((R_1, R_2)\) and on \((n_1, n_2)\), as long as it is independent of \(T\). We have also used the positivity and quadratic nature of the height \([16, \text{VIII \S9}]\) in the form
\[ h(nT + R) = n^2 h(T) + O_{E,R} \left( \sqrt{h(T)} \right). \]
It remains to bound \( \gcd(D_{n_1 T + R_1}, D_{n_2 T + R_2}) \). Since \( \gcd(n_1, n_2) = 1 \) by assumption, we can choose integers \( (u_1, u_2) \) with \( u_1 n_1 + u_2 n_2 = 1 \) and set \( R_3 = u_1 R_1 + u_2 R_2 \). Note that \( R_3 \) is independent of \( T \). Let \( p \) be a prime. Working in \( E(Q_p) \), we have

\[
p^e | \gcd(D_{n_1 T + R_1}, D_{n_2 T + R_2})
\]

\[
\iff n_1 T + R_1 \equiv O \pmod{p^e} \quad \text{and} \quad n_2 T + R_2 \equiv O \pmod{p^e}
\]

\[
\implies T + R_3 = u_1 (n_1 T + R_1) + u_2 (n_2 T + R_2) \equiv O \pmod{p^e}
\]

\[
\implies p^e | D_{T + R_3}.
\]

Thus \( \gcd(D_{n_1 T + R_1}, D_{n_2 T + R_2}) \) divides \( D_{T + R_3} \), so

\[
\log \gcd(D_{n_1 T + R_1}, D_{n_2 T + R_2}) \leq \log D_{T + R_3} \leq h(T + R_3) \leq h(T) + O(\sqrt{h(T)}). \quad (16)
\]

Combining (15) and (16) yields

\[
h(T) \geq \epsilon(n_1^2 + n_2^2)h(T) + O(\sqrt{h(T)}) \quad \text{for infinitely many} \ T \in E(Q).
\]

Letting \( h(T) \to \infty \), we conclude that

\[
1 \geq \epsilon(n_1^2 + n_2^2). \quad (17)
\]

This completes the proof of Theorem 3 once we observe that the height function \( H(P) \) used in the statement of Theorem 3 satisfies \( \log H(P) = 2h_{E,O}(P) \).

**Proof of Theorem 4.** This time we apply Theorem 6 with

\[
X = E \times \mathbb{P}^1,
\]

\[
A = \pi_1^*(O) + \pi_2^*(\infty),
\]

\[
K_X = -\pi_2^*(0) - \pi_2^*(\infty),
\]

\[
Y = \{(O, 1)\},
\]

where \( \pi_1 : X \to E \) and \( \pi_2 : X \to \mathbb{P}^1 \) are the projections. Then for any \((Q, b) \in E(Q) \times \mathbb{Z}\) we have

\[
h_{X,A}(Q, b) = h_{E,O}(Q) + h(b)
\]

\[
h_{\gcd}((Q, b); (0, 1)) = \log \gcd(D_Q, b - 1).
\]

Further, if \( b \in \mathbb{Z}_S^\times \), then

\[
h'_{X,-K_X,S}(Q, b) = h'_{\mathbb{P}^1,(0),S}(b) + h'_{\mathbb{P}^1,(\infty),S}(b) = 0.
\]
Thus Theorem 6 yields

$$\log \gcd(D_Q, b - 1) \leq \varepsilon (h_{E,Q}(Q) + h(b)) + O(1)$$

for \((Q, b) \in E(Q) \times \mathbb{Z}_S^*\) with \((Q, b) \notin Z\).

Siegel’s theorem [16, IX.3.3] says that \(h_{E,Q}(Q) \sim \log D_Q\) as \(h_{E,Q}(Q) \to \infty\), so exponentiating and adjusting \(\varepsilon\) gives

$$\gcd(D_Q, b - 1) \leq C \cdot \max(D_Q, b)^{\varepsilon}$$

for \((Q, b) \in E(Q) \times \mathbb{Z}_S^*\) with \((Q, b) \notin Z\).

It remains to deal with the exceptional set \(Z\). It suffices to consider an irreducible component \(\Gamma \subset Z\) of dimension 1 with

$$\log \gcd(D_Q, b - 1) \geq \varepsilon (h_{E,Q}(Q) + h(b)) + O(1)$$

for infinitely many \((Q, b) \in (E(Q) \times \mathbb{Z}_S^*) \cap \Gamma\). (18)

In particular, \(\#\Gamma(Q) = \infty\), so Faltings’ theorem [8] reduces us to the case that \(\Gamma\) has genus 0 or 1. If either \(\pi_1(\Gamma)\) or \(\pi_1(\Gamma)\) consists of a single point, it suffices to adjust the constant, so we assume that \(\pi_1(\Gamma) = E\) and \(\pi_2(\Gamma) = \mathbb{P}^1\). In particular, the fact that \(\pi_1(\Gamma) = E\) implies that \(\Gamma\) cannot have genus 0, so we are reduced to the case that \(\Gamma\) has genus 1.

The fact that \(\Gamma\) satisfies (18) implies that \(\pi_2(\Gamma) \cap \mathbb{Z}_S^*\) is infinite. In other words, the map

$$\pi_2 : \Gamma(Q) \longrightarrow \mathbb{Q} \cup \{\infty\}$$

takes on infinitely many \(S\)-unit values. But \(\Gamma(Q)\) is the Mordell-Weil group of an elliptic curve, so Siegel’s theorem [16, IX.3.2.2] says that this is not possible (indeed, it is not even possible to take on infinitely many \(S\)-integral values). This completes the proof that the exceptional set may be taken to be a finite set of points, and hence may be eliminated entirely by adjusting the constants. \(\square\)

6. Divisibility sequences and algebraic groups

A divisibility sequence is a sequence of integers \((a_n)_{n \geq 1}\) with the property that

$$m|n \implies a_m|a_n.$$  

We have already briefly discussed the divisibility sequences \((D_{nP})\) associated to a point of infinite order \(P\) on an elliptic curve \(E(Q)\). Other familiar divisibility sequences include sequences of the form \((a^n - b^n)\) and the Fibonacci sequence \((F_n)\). There are many natural ways to generalize the notion of divisibility sequence, for example by replacing divisibility of positive integers with divisibility of ideals in a ring. In
the most abstract formulation, one might define a divisibility sequence as simply an order-preserving maps between two partially ordered sets (posets). In this section we restrict our attention to classical divisibility sequences of rational integers, but the reader should be aware that virtually everything that we say can be easily generalized (albeit at the cost of some notational inconvenience) to the partially ordered set of integral ideals in number fields, and in some cases to other Dedekind domains or even more general rings.

The divisibility sequence \((a^n - b^n)_{n \geq 1}\) is naturally associated to the rank one subgroup of \(\mathbb{G}_m(\mathbb{Q})\) generated by \(a/b\), just as the divisibility sequence \((D_{nP})_{n \geq 1}\) comes from the rank one subgroup of \(E(\mathbb{Q})\) generated by \(P\). This suggests creating divisibility sequences from other algebraic groups \(G\) defined over \(\mathbb{Q}\). In order to make this precise, we need to choose a model over \(\mathbb{Z}\), although a a different choice of model only changes the sequence at finitely many primes.

**Definition 4.** Let \(G/\mathbb{Z}\) be a group scheme over \(\mathbb{Z}\), let \(O \subset G(\mathbb{Z})\) be the identity element of \(G\), and let \(P \in G(\mathbb{Z})\) be a nonzero section. We associate to \(P\) a positive integer \(D_P\) by the condition

\[
\text{ord}_p(D_P) = (P \cdot O)_p
\]

for all primes \(p\), where in general \((P_1 \cdot P_2)_p\) denotes the arithmetic intersection index of the sections \(P_1\) and \(P_2\) on the fiber over \(p\).

Equivalently, let \(\mathcal{I}_O\) be the ideal sheaf of \(O \subset G\), where we identify the section \(O\) with its image \(O(\mathbb{Z})\), taken with the induced reduced subscheme structure. Then \(P^*(\mathcal{I}_O)\) is an ideal sheaf on \(\text{Spec}(\mathbb{Z})\), i.e. it is an ideal of \(\mathbb{Z}\). Then \(D_P\) is determined by the condition that it generates this ideal,

\[
D_P \cdot \mathbb{Z} = (P)^*(\mathcal{I}_O).
\]

These \(D_P\) values are closely associated to certain generalized greatest common divisors.

**Proposition 7.** Let \(G/\mathbb{Z}\) be a group scheme, let \(G = G \times_{\mathbb{Z}} \mathbb{Q}\) be the associated algebraic group over \(\mathbb{Q}\), and let \(\rho : G(\mathbb{Z}) \to G(\mathbb{Q})\) denote restriction to the generic fiber, and let \(O = \rho(O) \in G(\mathbb{Q})\) be the identity element of \(G\). Then

\[
\log D_P \leq h_{\gcd}(\rho(P); O) + O(1) \quad \text{for all } P \in G(\mathbb{Z}).
\]

(In principle, the height function might depend on the choice of a completion and projective embedding of \(G\). However, these only affect \(h_{\gcd}(\cdot; O)\) up to \(O(1)\).)
Proof. This is just a matter of unsorting the definitions and decomposing $h_{\gcd}$ into a sum of local heights. With the obvious notation, we find that

$$\lambda_{\gcd}(\rho(\mathcal{P}); O; v) = \lambda_{\tilde{G}, \tilde{O}}(\rho(\mathcal{P}), v) = v(D_{\mathcal{P}})$$

for all nonarchimedean places $v$.

This gives the stated result, with the contributions from the (nonnegative) archimedean local heights giving an inequality, rather than an equality. □

We next show that a sequence of the form $(D_n \mathcal{P})_{n \geq 1}$ is a divisibility sequence.

**Proposition 8.** Let $\mathcal{G}/\mathbb{Z}$ be a group scheme and let $\mathcal{P} \in \mathcal{G}(\mathbb{Z})$ be a point (section) of infinite order. Then the sequence $(D_n \mathcal{P})_{n \geq 1}$ is a divisibility sequence. We call it the divisibility sequence associated to $\mathcal{P}$ (and $\mathcal{G}$).

**Proof.** For each integer $n \geq 1$, let $\mu_n : \mathcal{G} \rightarrow \mathcal{G}$ be the $n$th-power morphism. The section $n \mathcal{P} \in \mathcal{G}(\mathbb{Z})$ is the composition

$$\text{Spec}(\mathbb{Z}) \xrightarrow{\mathcal{P}} \mathcal{G} \xrightarrow{\mu_n} \mathcal{G}.$$ Now let $m|n$, say $n = mr$. Then

$$D_n \mathcal{P} \cdot \mathbb{Z} = (n \mathcal{P})^*(\mathcal{I}_\mathcal{O}) = (\mu_n \circ \mathcal{P})^*(\mathcal{I}_\mathcal{O}) = (\mu_r \circ \mu_m \circ \mathcal{P})^*(\mathcal{I}_\mathcal{O}) = (\mu_m \circ \mathcal{P})^* \circ \mu_r^*(\mathcal{I}_\mathcal{O}) \subseteq (\mu_m \circ \mathcal{P})^*(\mathcal{I}_\mathcal{O}) = (m \mathcal{P})^*(\mathcal{I}_\mathcal{O}) = D_m \mathcal{P} \cdot \mathbb{Z}$$

by definition of $D_n \mathcal{P}$, since $n \mathcal{P} = \mu_n \circ \mathcal{P}$ as maps, since $\mu_n = \mu_{rm} = \mu_r \circ \mu_m$, since $\mu^*_r(\mathcal{I}_\mathcal{O}) \subseteq \mathcal{I}_\mathcal{O}$, by definition of $D_m \mathcal{P}$.

The one point that possibly requires further explanation is the inclusion $\mu^*_r(\mathcal{I}_\mathcal{O}) \subseteq \mathcal{I}_\mathcal{O}$ of ideal sheaves on $\mathcal{G}$. The validity of this inclusion follows from the following two facts:

- The sheaf $\mathcal{I}_\mathcal{O}$ is the ideal sheaf of the image $\mathcal{O}(\mathbb{Z})$ of the identity section with its induced-reduced subscheme structure.
- The zero section satisfies $r\mathcal{O} = \mathcal{O}$, so $\mu_r(\mathcal{O}(\mathbb{Z})) = (r\mathcal{O})(\mathbb{Z}) = \mathcal{O}(\mathbb{Z})$ as subsets of $\mathcal{G}$.

This proves that $D_n \mathcal{P} \cdot \mathbb{Z} \subseteq D_m \mathcal{P} \cdot \mathbb{Z}$, which is equivalent to $D_m \mathcal{P} | D_n \mathcal{P}$. □

**Definition 5.** A geometric divisibility sequence is the divisibility sequence $(D_n \mathcal{P})_{n \geq 1}$ associated to a point (section) $\mathcal{P}$ of infinite order in a group scheme $\mathcal{G}/\mathbb{Z}$ as in Proposition 8.
In some cases an algebraic group $G/\mathbb{Q}$ has a particularly nice model over $\mathbb{Z}$, as for example is the case for abelian varieties. This prompts the following definition.

**Definition 6.** Let $A/\mathbb{Q}$ be an abelian variety and let $P \in A(\mathbb{Q})$ be a point of infinite order. The *abelian divisibility sequence* associated to $P$ is the divisibility sequence associated to the lift $\mathcal{P}$ of $P$ to a section of the Néron model $A/\mathbb{Z}$ of $A/\mathbb{Q}$. By abuse of notation, we denote this sequence by $(D_{nP})_{n \geq 1}$.

We next show that Vojta’s conjecture implies a strong upper bound for abelian divisibility sequences on abelian varieties of dimension at least 2. This result generalizes Theorem 3 (take $A = E \times E$).

**Proposition 9.** Let $A/\mathbb{Q}$ be an abelian variety of dimension at least 2, and assume that Vojta’s conjecture is true for $A$ blown up at $O$. Fix a Weil height

$$h : A(\mathbb{Q}) \to \mathbb{R}$$

on $A$ with respect to an ample symmetric divisor.

(a) For every $\epsilon > 0$ there is a constant $C = C(A, \epsilon)$ and a proper algebraic subvariety $Z \subsetneq A$ so that

$$h_{\gcd}(P; O) \leq \epsilon h(P) + C \quad \text{for all } P \in A(\mathbb{Q}) \setminus Z.$$  

The exceptional set $Z$ consists of a finite union of translates of nontrivial abelian subvarieties of $A$, so in particular, if $A$ is simple, then we may take $Z = \emptyset$.

(b) Let $(D_{nP})_{n \geq 1}$ be the abelian divisibility sequence associated to a point of infinite order $P \in A(\mathbb{Q})$, and assume further that the group $\mathbb{Z}P$ generated by $P$ is Zariski dense in $A$. Then for every $\epsilon > 0$ there is a constant $C = C(A, P, \epsilon)$ so that

$$\log D_{nP} \leq \epsilon n^2 + C \quad \text{for all } n \geq 1.$$  

**Remark 3.** We observe that Proposition 9 is false if $A$ is an elliptic curve, since then we have $h_{\gcd}(P; O) = h_{E,O}(P)$ and $\log D_{nP} \sim n^2 h(P)$. The reason that our proof of Proposition 9 fails when $\dim(A) = 1$ is the requirement in Theorem 6 that the subvariety $Y$ have codimension at least 2 in $X$.

**Proof of Proposition 9.** (a) We apply Theorem 6 to the variety $A$, the subvariety consisting of the single point $O$, and the ample divisor used to define the height (19). The canonical divisor on $A$ is trivial, so Theorem 6 says that there is a subvariety $Z \subsetneq A$ such that

$$h_{\gcd}(P; O) \leq \epsilon h(P) + O(1) \quad \text{for all } P \in A(\mathbb{Q}) \setminus Z.$$
This proves (a), other than the characterization of \(Z\). Let \(Z' \subset Z\)
be any irreducible subvariety of \(Z\). If \(Z'(Q)\) is finite, then we may
discard it and adjust the \(O(1)\) accordingly. And if \(Z'(Q)\) is infinite,
then Faltings’ theorem [9] says that \(Z'\) is a translate of an abelian
subvariety of \(A\).

(b) We compute

\[
\log D_{nP} \leq h_{\gcd}(nP; O) + O(1) \quad \text{from Proposition 7,}
\]
\[
\leq \epsilon h(nP) + O(1) \quad \text{from (a), assuming } nP \notin Z,
\]
\[
\leq \epsilon n^2 \hat{h}(P) + O(1) \quad \text{canonical height property [11, B.5.1]}
\]

The fact that \(P\) has infinite order implies that \(\hat{h}(P) > 0\), so after replacing \(\epsilon\) with \(\epsilon/\hat{h}(P)\), this completes the proof of (b) provided \(nP \notin Z\).

Suppose that \(Z \neq \emptyset\), and let \(Z_1\) be an irreducible component of \(Z\)
that contains infinitely many multiples of \(P\). From (a), we know that
\(Z_1 = A_1 + R_1\) for an abelian subvariety \(A_1 \subset A\) and a point \(R_1 \in A(Q)\).
Choose \(n_2 > n_1\) with \(n_1 P \in Z_1\) and \(n_2 P \in Z_1\). Then \((n_2 - n_1)P \in A_1\).
Letting \(N = n_2 - n_1\), it follows that \(P \in A_1 + A[N]\), and hence that
\(nP \in A_1 + A[N]\) for all \(n \geq 1\). This contradicts the assumption that \(ZP\)
is Zariski dense in \(A\), and hence there is no exceptional set. \(\square\)

7. Final remarks and questions

We have proven a number of strong bounds for generalized greatest
common divisors and divisibility sequences, all conditional on the valid-
ity of Vojta’s beautiful, but deep, conjecture applied to an appropriate
blowup variety. It would be of great interest to find unconditional
proofs of some of these results.

In addition to height bounds, there are many other natural questions
that one might ask about abelian, or more generally geometric, divisi-
bility sequences. For example, which such sequences contain infinitely
many prime numbers (cf. [7]). This is, of course, a notoriously difficult
question, even for the simplest divisibility sequence \(2^n - 1\). There is
some evidence [5] that elliptic divisibility sequences \((D_{nP})_{n \geq 1}\)
donot contain infinitely many primes, although more general elliptic divis-
ibility “sequences” \((D_{nP + mQ})_{m,n \geq 1}\) may well contain infinitely many
primes.

One might ask if a geometric divisibility sequence necessarily grows,
or if it often returns to small values. For example, Ailon and Rudnick [1]
conjecture that if \(a, b \in \mathbb{Z}\) are multiplicatively independent, then

\[
gcd(a^n - 1, b^n - 1) = \gcd(a - 1, b - 1) \quad \text{for infinitely many } n \geq 1.
\]
They prove a strong version of this with $\mathbb{Z}$ replaced by the polynomial ring $\mathbb{C}[T]$. (See also [18] and [19] for analogs over $\mathbb{F}_q[T]$ and for elliptic curves.) We certainly suspect that the same is true for semiabelian varieties.

**Conjecture 10.** Let $G/\mathbb{Z}$ be a group scheme, let $P \in G(\mathbb{Z})$ be a $\mathbb{Z}$-valued point, and assume that the following are true:

1. The generic fiber $G = G \times_{\mathbb{Z}} \mathbb{Q}$ is an irreducible commutative algebraic group of dimension at least 2 with no unipotent part.
2. Let $P \in G(\mathbb{Q})$ be the restriction of $P$ to the generic fiber. Then the subgroup $\mathbb{Z}P$ generated by $P$ is Zariski dense in $G$.

Then the geometric divisibility sequence $(D_{nP})_{n \geq 1}$ corresponding to $P$ satisfies

$$D_{nP} = D_P \quad \text{for infinitely many } n \geq 1.$$

It is tempting to guess that something similar is true for geometric divisibility sequences associated to any irreducible algebraic group of dimension at least 2, regardless of whether or not it is commutative. (Note that the Zariski density condition is vital.) But with no significant evidence for even Conjecture 10, we will be content to leave the general case as a question.
