Hemoglobinopathies are very common in Oman (partly due to high consanguineous marriage), with an estimate of more than two per 1000 live births affected. The prevalence of a serious hemoglobinopathies is about 10% with the most significant being sickle cell anemia (SCA) and β-thalassemia major.

SCA is marked by a point mutation, where glutamic amino acid is replaced by valine leading to abnormal β chain production. About 40% of hemoglobin in the sickle cell trait (heterozygous state) is HbS, but in the homozygous state it can reach up to 80–95%. HbS can polymerize under the low oxygen tension, causing vaso-occlusive events leading to tissue inflammation, infarction, and end organ damage. The disease is characterized by the triad of recurrent painful episodes (crises): hemolytic anemia, and a predisposition to repeated infections. The clinical manifestations of SCA vary from patient to patient, and it is influenced by hereditary and environmental factors, including the level of fetal hemoglobin in postnatal life.

SCA patients are at an increased risk of infections, due to splenic dysfunction, altered complement regulation, low oxygen tension, medications, and recurrent admissions to hospital with exposure to nosocomial pathogens. The prevalence of infections has apparently increased owning to the improved diagnostics in recent times.

Among these infections, respiratory viral infections are very common, and can affect both upper and lower respiratory tract. The Cooperative Study of Sickle Cell Disease in the US demonstrated that viruses contributed to 6.7% of cases progressing to acute chest syndrome (ACS). Previous studies showed that three new respiratory viruses had emerged, namely SARS (a novel Corona virus) in
2003, influenza A H5N1 (avian flu) in 2004, and the pandemic caused by the new reasserting influenza A (H1N1) in April 2009, which was first identified in Mexico and California with subsequent spread worldwide. In Oman, 2681 persons were reported to be infected with the influenza A (H1N1) virus, of which 24 patients died, with these deaths occurring in the very young, elderly, or those with underlying disease.

Respiratory infections are a risk factor for triggering ACS in SCA patients and often lead to several complications. Influenza-associated hospitalization and complications in pediatric SCA patients were reported to be 56-times higher than in non-SCA patients. Measures to control these infections will immensely benefit these patients, who are highly susceptible to infections; in particular with increasing prevalence of viral infections after the pandemic of H1N1. The Center for Disease Control and Prevention also recommends regular vaccination for the prevention and control of seasonal influenza, and this is essential in SCA patients with their inherent immunocompromised state.

However, there has been limited data in the published literature studying the effect of respiratory viral infections and in particular H1N1 infections on SCA patients. A report from the UK estimated H1N1 in 50% of patients with SCA presenting to hospital with 25% developing ACS. Another report found that in 48 cases of H1N1 influenza, 21% progressed to ACS. A study in children and young adults with SCA identified 29 cases of confirmed H1N1 infection, with 34% developing ACS and 17% required intensive care including mechanical ventilation in 10%.

Our aim was to establish the clinical, laboratory, and radiological manifestations of respiratory viral infections in SCA patients at Sultan Qaboos University Hospital (SQUH) and assess its impact on the disease morbidity and mortality, with special emphasis on H1N1.

METHODS

We conducted a retrospective electronic medical record (EMR) review after approval by the local hospital medical research and ethics committee (MREC #1321). A list of 428 patients with SCA who were tested for viral infections were obtained from the EMR, but only 84 patients with a total of 109 episodes met all the inclusion criteria. These were: aged ≥ 15 years, confirmation of SCA by high-performance liquid chromatography and/or DNA studies, and confirmed to have respiratory viral infection by molecular studies (viral RNA/DNA PCR). All of these events occurred in the study period between June 2013 and July 2018. Demographic information, past medical history, clinical and laboratory findings, chest radiographs, complications, co-infections, interventions, and drugs given related to the episodes of respiratory viral infections in these patients were retrieved for analysis.

We used SPSS (IBM Corp. Released 2015. IBM SPSS Statistics for Windows, Version 23.0. Armonk, NY: IBM Corp.) to analyze the collected data. Continuous variables were expressed as mean and standard deviation if normally distributed, and median and inter quartile range (IQR) for data not following normal distribution. Nonparametric tests like chi-square was used to determine the statistical significance and the unpaired t-test Wilcoxon signed ranks test were used to compare means of continuous variables between groups. A p-value < 0.050 was considered significant.

RESULTS

Males and females were equally represented (n = 42 each) in our cohort. The mean age was 27.0±7.0 years (range = 15–57 years). Admission episodes were equally divided with 55 and 54 episodes in the male and female patients, respectively. Clinical details and confounding factors showed that 89.0%
of patients were on penicillin prophylaxis, whereas 61.5% were on hydroxyurea therapy. On abdominal ultrasound, 38.5% showed asplenia, either owing to surgical splenectomy or autosplenectomy, whereas 58.7% had a previous history of ACS.

Generally, the clinical presentations were similar in all types of respiratory viral infections. The most frequent signs and symptoms seen in these SCA patients were pain (87.2%), fever (55.1%) with a mean duration of 3.0 days, and cough (55.1%) ranging from dry to productive. Other frequent symptoms were throat congestion (23.8%), crepitation (22.9%), chest pain (22.1%), reduced air entry (16.5%), headache (11.9%), and rhinorrhea (14.7%) [Figure 1]. Comparatively, H1N1 patients had a higher incidence of cough (72.7% vs. 53.1%), rhinorrhea (36.4% vs. 14.7%), reduced air entry (18.2% vs. 16.3%), and crepitation (27.3% vs. 22.9%) than other non-H1N1 respiratory viral infected SCA patients in this cohort.

Table 1 shows the details of hematological parameters by comparison between the baseline and the time of infection. It was observed that the median hemoglobin at baseline was significantly higher than the median hemoglobin [nadir] during the infection. The mean white blood cell count at baseline was significantly decreased during infection as was the mean platelets count. The median reticulocyte count at baseline was significantly higher than during infection. The median lymphocytes count at baseline was significantly lower than the median lymphocytes during the infection.

Table 2 summarizes the biochemical parameters. We observed that the median C-reactive protein (CRP) level at admission was significantly lower than the median CRP during the infection.

### Table 1: Hematological laboratory investigations of the study population.

| Characteristics                  | Median | IQR   | Mean  | ± SD  | p-value |
|----------------------------------|--------|-------|-------|-------|---------|
| Hemoglobin baseline, g/dL        | 11.45  | 1.50  | 9.8   | 1.3   | < 0.001*|
| Hemoglobin nadir, g/dL           | 7.25   | 1.20  | 7.2   | 0.9   |         |
| WBC baseline, \( \times 10^9/L \) | 8.40   | 6.50  | 8.9   | 3.4   | < 0.002*|
| WBC nadir, \( \times 10^9/L \)   | 7.20   | 4.70  | 6.8   | 2.5   |         |
| Lymphocytes count baseline, \( \times 10^9/L \) | 2.70   | 0.90  | 2.6   | 0.8   | < 0.001* |
| Lymphocytes count maximum, \( \times 10^9/L \) | 3.70   | 1.80  | 4.1   | 2.0   |         |
| Platelets count baseline, \( \times 10^9/L \) | 313.00 | 233.00 | 350.6 | 252.4 | < 0.001* |
| Platelets count nadir, \( \times 10^9/L \) | 238.50 | 232.00 | 285.2 | 207.9 |         |

| ANC nadir, \( \times 10^9/L \)    | 2.60   | 1.60  | 2.5   | 1.2   |         |
| Reticulocyte baseline, \( \times 10^9/L \) | 214.50 | 230.90 | 223.1 | 129.2 | < 0.005* |
| Reticulocyte nadir, \( \times 10^9/L \) | 169.50 | 84.00  | 172.0 | 155.2 |         |
| HbS, %                           | 85.10  | 7.00  | 86.3  | 3.8   |         |
| HbF, %                           | 8.00   | 9.40  | 8.3   | 4.7   |         |

IQR: inter quartile range; SD: standard deviation; WBC: white blood cell; ANC: absolute neutrophil count; HbS: sickle cell hemoglobin; HbF: fetal hemoglobin.
*Statistically significant (Wilcoxon signed ranks test).

### Table 2: Biochemistry laboratory investigations of the study population.

| Characteristics                  | Median | IQR     | Mean  | ± SD  | p-value |
|----------------------------------|--------|---------|-------|-------|---------|
| LDH baseline, U/L                | 350.00 | 162.00  | 338.0 | 105.0 | < 0.001* |
| LDH maximum, U/L                 | 710.50 | 991.00  | 693.0 | 132.0 |         |
| CRP at admission, mg/L           | 18.50  | 41.00   | 37.7  | 21.8  | < 0.001* |
| CRP maximum, mg/L                | 143.50 | 147.00  | 153.0 | 44.4  |         |
| BUN, mmol/L                      | 3.80   | 1.70    | 3.4   | 0.8   |         |
| Total bilirubin, µmol/L          | 29.00  | 51.00   | 53.8  | 17.6  |         |
| Direct bilirubin, µmol/L         | 12.50  | 28.00   | 47.9  | 14.1  |         |

IQR: inter quartile range; SD: standard deviation; LDH: lactate dehydrogenase; CRP: C-reactive protein; BUN: blood urea nitrogen.
*Statistically significant (Wilcoxon signed ranks test).
Median lactate dehydrogenase (LDH) significantly increased to from its baseline value during the infection.

Abnormal chest radiological findings were present in 25.0%, with segmental (10.0%) or multi-segmental atelectasis (8.0%), and acute respiratory distress syndrome (ARDS) (7.0%). Pleural effusions were seen in 22.0% with 19.0% going through a mild course, but 3.0% had a moderate effusion.

Figure 2 shows the interventions and complications in these patients with respiratory virus infection. Interventions included blood transfusions (44.9%), non-invasive ventilation (12.8%), need for central venous catheter (7.3%), and urinary catheter (3.7%). One-third (32.1%) of these episodes were complicated by ACS and associated with one death.

Overall, two patients died in this cohort and both the patients were infected with parainfluenza 3 virus. The first patient had a co-associated Salmonella and developed sepsis and died. The second patient had a co-associated ACS and developed seizures with neurological symptoms and bradycardia that was managed by implantable cardiac defibrillator, but the patient also died.

Figure 3 shows the spectrum of respiratory viruses (n = 125) observed in this study with 10.1% showing H1N1. The most prevalent non-H1N1 respiratory virus infection was rhinovirus (35.8%) followed by adenovirus (16.5%), influenza A (14.7%), respiratory syncytial virus (12.8%), influenza B (11.9%), parainfluenza 3 (6.4%), parainfluenza 4 (2.8%), enterovirus (1.8%), and parainfluenza

### Table 3: Comparison of clinical presentations, radiological features, interventions, and complications between H1N1 infected patients (n = 10) and other respiratory viruses (n = 74).

| Variables                  | Patients with H1N1 (VOC = 11) n (%) | Patients without H1N1 (VOC = 98) n (%) | p-value Chi-square test |
|----------------------------|-------------------------------------|--------------------------------------|-------------------------|
| Pain                       | 9 (81.8)                            | 86 (87.7)                            | 0.88*                   |
| Fever                      | 6 (54.5)                            | 54 (55.1)                            | 1.00*                   |
| Cough                      | 8 (72.7)                            | 52 (53.1)                            | 0.52*                   |
| Chest pain                 | 2 (18.2)                            | 22 (22.4)                            | 0.38*                   |
| Reduced air entry          | 2 (18.2)                            | 16 (16.3)                            | 1.00*                   |
| Crepitations               | 3 (27.3)                            | 22 (22.4)                            | 0.77*                   |
| Rhinorrhea                 | 4 (36.4)                            | 12 (12.2)                            | 0.19*                   |
| Acute chest syndrome       | 2 (18.2)                            | 33 (33.7)                            | 0.43*                   |
| Non-invasive ventilation   | 1 (9.1)                             | 13 (13.3)                            | 0.72*                   |
| Blood transfusion          | 4 (36.4)                            | 45 (45.9)                            | 0.70*                   |
| Death                      | 0 (0.0)                             | 2 (2.0)                              |                         |

*Not significant (p > 0.050); VOC: vaso-occlusive crisis.
In all cases, the diagnosis of the specific viral infection was made by molecular studies with reverse-transcriptase polymerase chain reaction to identify the relevant viral RNA or DNA.

In 84.4%, infection was due to a single virus, whereas in the remaining 15.6%, multiple viral organisms were found. Importantly, less than a third of these patients with multiple viruses were associated with ACS (23.5%), but significantly, all H1N1 cases were co-associated with influenza A virus (100%). Additionally, bacterial co-infection in five instances with six different microorganisms, and two instances of a co-infection with both a viral and a fungal microorganism were also observed.

Table 3 shows the comparison of the clinical and radiological features, interventions, and complications in patients with and without H1N1 infections. There were no statistically significant differences seen.

Almost all these patients received empiric therapy with antibiotics and antiviral agents, namely oseltamivir (n = 78, 92.9%), azithromycin (n = 72, 85.7%), piperacillin/tazobactam (n = 53, 63.1%), moxifloxacin (n = 52, 6.9%), and cefuroxime (n = 40, 47.6%).

**DISCUSSION**

The purpose of this study was to establish the clinical, laboratory, and radiological manifestations of respiratory viral infections in SCA patients, and assess its impact on disease morbidity and mortality, with a special emphasis on H1N1. Our data showed that these patients presented with upper respiratory tract infection symptoms with varying degrees of severity, but there were no significant differences in clinical presentations between the different types of the respiratory viruses. We observed more severe symptoms in patients infected with adenovirus and parainfluenza 3 virus. These findings were consistent with the previous reports on the impact of respiratory viruses in patients with SCA. Two-thirds of this cohort were on hydroxyurea and had a history of ACS. One-third had splenectomy or asplenia, with ACS seen in 32.1% with a low mortality. Treatment with hydroxyurea may have had a positive impact on this outcome.

The mean age in H1N1 patients was higher than the non-H1N1 patient cohort (28.8 vs. 26.5 years). There were no differences in the common symptoms of infection between the two groups; in H1N1 patients, fever and rhinorrhea were relatively predominant, whereas in the non-H1N1 patient’s painful episodes, blood transfusions, and ACS were more prominent, but these differences were not statistically significant [Table 3]. The clinical course in the H1N1 patients was mild with only two patients needing morphine and one needing chest physiotherapy and incentive spirometry. It was known that H1N1 infections were more severe in the older age and previous pediatric reports showed significant morbidity.

Although the cooperative sickle cell study from US demonstrated that viruses contributed to only 6.7% of cases of ACS, influenza-associated hospitalization in SCA is reported to be 56-times higher. George et al, reported that the impact of H1N1 influenza pandemic on SCA patients was mild, with 21% progressing to ACS. A prior study by Strouse et al, had also reported significant morbidity. In their study on H1N1 influenza patients, 34% progressed to ACS, requiring intensive care in 17%, while 10% needed mechanical ventilation. In our H1N1 cohort (n = 11), two (18.2%) patients progressed to ACS, and although none needed intensive care, one (9.1%) required non-invasive ventilation, but there was no death in this subgroup of patients. We believed that the overall improvement in the SCA management may be responsible for these improved outcomes, as well as the role of early institution of oseltamivir needs to be emphasized, as all our patients received it early, when the diagnosis was suspected.

Expectedly, the laboratory parameters worsened after infection, similar to previous studies. We found a decline in oxygen saturation and hemoglobin levels with development of thrombocytopenia, leucopenia, and lymphocytosis. In addition, there was significant increase in CRP and serum LDH indicating intense ongoing inflammation with ischemia and tissue infarction. These findings were similar to previous reports on all respiratory viruses in SCD.

Monitoring by chest imaging was done in all patients, as they were most likely to trigger the development of ACS. Our findings showed that the most severe radiological changes were seen with adenoviruses. A study from Korea reported that adenovirus pneumonia progressed to ARDS in 63%, with 50% mortality. Adenovirus respiratory infections are usually associated with bilateral patchy parenchymal or ground-glass opacities on chest
radiographs. The predominant radiological pattern seen in H1N1 infection was bilateral ground-glass opacities and alveolar consolidation. However, the radiological changes seen in H1N1 cases in this study were mild and unilateral.

Although the number of H1N1 patients in this cohort was small, we feel that the improved management of SCA in general and specifically the early administration of oseltamivir may have played an important role here. Nevertheless, further larger prospective studies will be needed to explain these differences.

It has been found that viral infections can promote bacterial adherence and immune-mediated interactions. Our study demonstrated that the co-infections were mostly detected with rhinovirus followed by adenovirus showing the highest prevalence of co-association with bacterial organisms. However, our study cohort showed a lower prevalence of bacterial co-infections (6.0%) than a previous study by Seo et al., that reported a prevalence of 26.5%. However, despite the low prevalence, there was prolonged hospital stay, more severe infection course, and higher mortality in these patients with bacterial co-infection.

CONCLUSION
To the best of our knowledge, this is the first study from Oman that reports the impact of respiratory viruses on clinical, radiological, and laboratory manifestations in SCA patients. Our findings indicated that SCA patients displayed a mild course of H1N1 infection and the most prevalent respiratory virus in this cohort was rhinovirus. Fever and cough were the most frequent presenting symptoms, leading to significant anemia, reticulocytopenia, leucopenia, and thrombocytopenia. Also, LDH and CRP were significantly elevated. Nearly one-third had ACS and almost half required blood transfusions. Further, the most severe course was seen in SCA patients infected with adenovirus or parainfluenza 3 virus, with mortality associated with the latter. However, studies with larger numbers of patients with respiratory viral infections in SCA are necessary to evaluate the predisposing risk factors to its development.
