Abstract: The traditional products’ quality is often recognized based on organoleptic characteristics without considering the microbiological features, which bring a special note to these products’ composition and aroma. It is especially the case of cheeses, whose taste varies from one geographical region to another depending on specific flora and technological processes used in traditional systems. The paper tries to bring new elements on the methodology used in order to elucidate some aspects related to traditional products’ quality, products obtained by private producers in the Braşov district (Rucăr-Bran pass). Covasna district and Bistrița-Nasaud district were analyzed organoleptically, physico-chemically and microbiologically samples of fresh cow cheese, soft cow cheese, smoked curd cheese, gaiter cheese and cottage cheese taken within the strategic and self-control program from individuals in the rural areas of Fundata, Poiana Sibiului, Șirnea, Părău, Cristian, Cincușor, Sohoodol, Rășnov, Brașov, Bod, Roadeș, Hărman, Prejmer, Șoarș, Rupea, Lunca Câlnicului, Bățani, Mari, Bran, Buziaș, Bărcut, Hâlchiu, Făgăraș, Moeciu de Sus, Purcăreni, Bran–Șimon, Venetia de Jos, Vama Buzăului, Șintura Buzăului, Vârgăș and Sita Buzăului.

Key words: Traditional cheese, Rucăr-Bran pass, microbiological quality.

1. Introduction

The traditional way of making cheeses are kept for centuries in the Rucăr-Bran pass and the surrounding areas, the whole process is passed down from a generation to another. It has several stages, specific to each kind of cheese and the end product has a particular flavor due to well developed maturation procedures [1]. Even if the stages were strictly kept, the appearance of a certain number of potentially pathogenic microorganisms is not excluded. The germs may appear accidentally in the raw or intermediary matte [2, 3]. They may multiply on favorable substrates in spontaneous, quick ways, especially if the temperature of the process is not being respected, the refrigeration being needed through the whole process; their development is also controlled by the predominant lactic bacilli flora [4].

The aim of this study was to microbiologically analyze the cheeses from Brașov, Covasna and Bistrița-Năsăud districts because the authors considered a compulsory issue the accumulation of data regarding the microbiology of traditional cheeses and also the implementation of the procedures regarding cheeses specified in the strategic plan of sanitary and veterinary supervision, prophylaxis and disease control by the Romanian Food Safety Authority; this plan was intended also for preventing the transmission of animal diseases to humans and for environment’s protection [5].

2. Materials and Methods

2.1 Cheese Samples

This study lasted three years (2009-2012) and consisted in sampling and analyzing seven types of
Romanian traditional cheeses. They were analyzed the sensory, physicochemical and microbiological features of those goods.

For evaluating the microbiological quality of traditional products made by local producers from Brașov, Covasna and Bistrița-Năsăud counties, 164 samples from different types of cheeses were used, as follows:

- 6 samples of fresh cow cheese;
- 13 samples of curd;
- 8 samples of sheep soft cheese, cow soft cheese and mixed soft cheese;
- 14 samples of smoked soft cheese;
- 5 samples of cow pressed cheese, one sample of traditional pressed cheese and one sample of yeasted pressed cheese;
- 40 samples of sheep cottage cheese, 48 samples of cow cottage cheese, 2 samples of goat cottage cheese and 8 samples of mixed cottage cheese;
- 18 samples of bellow cheese.

The samples were split into seven lots, each lot being analyzed according to the European legislation in force, given the previous cases of suspicion or disease outbreak from each investigated area, emerged before the beginning of the study.

The microbiological analyzes were carried out in order to demonstrate the presence of pathogen bacteria like the Salmonella genus (positive or negative in 25 g of sample), Listeria monocytogenes genus (positive or negative 25 g in of sample) and also in order to detect problems caused by the eventual violations of hygienic procedures by establishing the total number of aerobic mesophilic bacteria (TVC/g), Escherichia coli (CFU/g) and Staphylococcus aureus coagulase-positive (CFU/g).

2.2 Methods of Microbiological Analysis

- Establishing the number of coliform bacteria (Gram-negative bacilli or coco bacilli, that ferment the lactose at 37 °C, with gas production)-the horizontal method of counting the colonies at 30 °C [6]. The coliformes were counted either on a solid culture medium (agar gel-deoxycholate-lactose), either in a liquid culture medium using the most probable number determination technique or the lactose broth with bile and brilliant green in Durham tubes (10 mL/tube).
  - Establishing the presumptive number of *Escherichia coli* (bacteria that ferments the lactose at 45 °C with the production of gases and also indole from tryptophan)-the technique of the most probable number [7]. This procedure uses the liquid culture medium and calculates the most probable number, after incubation at 35 °C and then at 45 °C; the number of *E. coli*/g was predicted using the horizontal method [8] and the TEMPO method.
  - Identifying the bacteria from the *Salmonella* genus (Gram-negative, mobile, unsporulated enterobacteria, common pathogens for humans and animals; there is a type which ferment the glucose with gas production on the one hand and another type that doesn’t ferment the glucose, but produces hydrogen sulfide and use citrate as only carbon source, don’t produce indole, neither urease and have antigenic structures that allow his serological identification, on the other hand), by using the horizontal method [9]. This procedure allows the identification of all bacteria from the *Salmonella* genus, including *S. typhi* and *S. paratyphi*. The principle of this method was the pre-enrichment of non-selective and selective liquid environments, then isolating and identifying the bacteria. In the end, the colonies considered to be *Salmonella* spp. were grown, isolated and then confirmed using biochemical and serological tests (for further confirmation the colonies were sent to another specialized laboratory to determine the serotype).
  - Identification of bacteria from the *Listeria monocytogenes* genus in 25 g of cheese [10] was carried out in four successive phases: firstly, the enrichment using a liquid selective culture medium with a reduced number of selective agents (semi-Fraser broth); secondly, the enrichment using a liquid selective culture medium with a normal number of
selective agents (Fraser broth); thirdly, the ribbing and identifying of bacteria; finally, the confirmation.

- Establishing the number of \textit{S. aureus} (Gram positive cocci, laid in a cluster, which form characteristic or non-characteristic colonies on the surface of a selective culture medium and have a strong reaction to coagulase) by using the solid Baird-Parker culture medium or the method of colonies’ counting after an aerobic incubation at 35 °C or 37 °C [11]. The method was based on the inoculation of the selective, solid culture medium using plates containing an exact quantity from the initial suspension. The inoculation was made in the same conditions, by using decimal dilutions of the sample or from the initial suspensions using two plates for each dilution. During the aerobic incubation of the plates, they were examined after 24 h and 48 h. The calculation of the coagulase-positive staphylococci number per milliliter or per gram was made considering the number of typical and/or atypical colonies formed on plates, using specific dilution levels in order to obtain relevant results, confirmed by the coagulase-positive test.

- Establishing the total number of total viable count (TVC/g) by using four stages, as follows: sampling and preparing the sample; obtaining the initial suspension of decimal dilutions; pouring the dilution on plates and incubating them; counting the developed colonies and calculating the total number of colonies per gram of sample.

2.3 Other Reference Materials

Regulation [12] establishes food safety criteria, the limits of acceptability of food products for human consumption and hygiene criteria for the work environment.

3. Results and Discussion

Although there are some cheeses called according to their copyrighted names and largely produced, the strictly traditional cheeses have limited distribution areas both nationwide and worldwide (they are little known in other countries with tradition in massive production of milk and cheeses).

In order to benefit from the advantages that the recognition of quality standards fulfillment may bring, the producers must meet a number of criteria as far as the quality’s homogeneity is to be achieved, even if the little fluctuations of flavor and taste is negligible for the consumers. This kind of criteria is hard to meet because of the traditional, seasonal features and low quantities of those cheeses made in some limited geographical areas such as the Rucăr-Bran pass and its surroundings.

Studying the fabrication methodology of traditional Romanian mountain cheeses obtained in the Rucăr-Bran pass and the surrounding areas, cheeses made by local private producers the authors distinguished some essential steps respected by generations of shepherds, which are the keepers of a prestigious past in sheep-herding.

The manufacturing methods are still at a traditional level, despite the emergence of modern mechanical and electronic devices, which would significantly improve the working conditions.

The results of microbiological analysis for fresh cheese samples did not reveal in any case the exceeding of \textit{E. coli} (CFU/g) number above the maximum allowed value of 102-103 CFU/g [12].

The results obtained from samples of curd demonstrate that the hygienic criteria of the process were met due to the low values obtained both for \textit{S. aureus} \textit{CP} (CFU/g) number and for \textit{E. coli} (CFU/g) number.

Two violations (\textit{S. aureus} CP 6 × 106 CFU/g, and \textit{E. coli} 3 × 103 CFU/g) of legal norms [12] were registered for curd sample No. 19, in this case, the hygiene criteria not being met. The maximum allowed value for \textit{S. aureus} (105 CFU/g) being exceeded by about six times a logarithm, and values above the permitted 103 CFU/g for \textit{E. coli} were measured. Consequently, the authors considered mandatory also the testing in order to detect staphylococcal enterotoxins. On this occasion, the hygiene’s improving during the manufacturing process was highly recommended.

Fig. 5  *S. aureus* CP, *E. coli* and TVC/g (CFU/g) in bellows cheese samples.

The pressed cheese samples did not exceed the maximum allowable values for *S. aureus* CP. For all analyzed samples, following the results’ interpretation, the lack of bacteria from the *Salmonella* genus was noted.

The 18 analyzed curd samples and the bellows cheese samples showed no increased value above the admissibility threshold criteria neither for processing hygiene indicators or finished product’s safety indicators.
Table 6  Microbiological analysis results for samples of cottage cheese.

| Probe                        | Lot size (kg) | Coagulase-positive staphylococcus | *Salmonella* spp. (prez.-abs./25 g) | *E. coli* (UFC/g) | *L. monocytogenes* (prez.-abs./25 g) |

The 98 cottage cheese samples, analyzed here, showed two violations of the processing hygiene conditions (E. coli $2.8 \times 10^3$ CFU/g and S. aureus CP $1.1 \times 10^5$ UFC/g) both being related to the general processing technology of obtaining the sheep cottage cheeses. The absence of pathogens like Salmonella spp. and L. monocytogenes was shown in all analyzed samples. The results are consistent with other studies [13, 14].

**4. Conclusions**

The microbiological research took four years and consisted in sampling and analyzing 164 samples of Romanian traditional cheeses from local producers and shepherds from: Brașov, Covasna and Bistrița-Năsăud districts.

The microbiological analysis was made in order to discover pathogens from the Salmonella and Listeria monocytogenes genus, as well as detecting the problems related with hygienic procedures implementation. The total number of aerobic mesophilic bacteria (TVC/g), Escherichia coli (CFU/g) and coagulase-positive Staphylococcus aureus (CFU/g) were established.

No pathogenic agents were found in any of the tested samples.
The microbiological analyzes showed the high degree of hygiene during processing and the good quality of Romanian traditional cheeses which are handmade foodstuff, obtained according to some technologies transmitted from a generation of shepherds to another, that today may be considered as rudimentary but are proving once again to be effective.

Despite the rudimentary processing technology, the cheeses made in the Rucăr-Bran pass present an outstandingly good quality, a characteristic taste appreciated by connoisseurs and have a low microbiological charge in the same time which makes them a valuable enrichment within a balanced diet.
