1. Introduction.

In the book [6], the authors studied the moduli spaces of bordered stable maps of genus 0 with Lagrangian boundary condition in a systematic way and constructed the filtered $A_\infty$-algebra associated to Lagrangian submanifolds. Since our construction depends on various auxiliary choices, we considered the canonical model of filtered $A_\infty$-algebras, which is unique up to filtered $A_\infty$-isomorphisms. The aim of this note is to explain the construction of the canonical model and to apply such an argument to obtain the filtered $A_\infty$-structure to the Morse complex on the Lagrangian submanifold. The resulting filtered $A_\infty$-operations are described by the moduli spaces of certain configurations consisting of pseudo-holomorphic curves and gradient flow lines. Note that the first named author [4] studied the quantization of Morse homotopy based on the moduli spaces of certain configurations consisting of pseudo-holomorphic discs and gradient flow lines of multiple Morse functions, see [13] for monotone case and Theorem A4.28 in §A.4 in [5]. Such configurations are also studied in monotone case by Buhovsky [2] and Biran and Cornea [1]. We follow Chapter 5 in [6] to explain the algebraic aspect of canonical models and use the geometric construction in Chapter 7 in [6].

We briefly review the background of our study. Floer [3] invented a new theory, which is now called Floer (co)homology for Lagrangian intersections. Very roughly speaking, it is an analog of Morse theory for the action functional on the space of paths with end points on Lagrangian submanifolds. For a transversal pair of Lagrangian submanifolds $L_0, L_1$, the cochain complex is generated by the intersection points of $L_0$ and $L_1$. The coboundary operator is defined by counting connecting orbits joining the intersection points. The theory was extended by the second named author [12] to the class of monotone Lagrangian submanifolds with the minimal Maslov number being at least 3. In general, however, there arise obstructions to constructing the Floer cochain complex caused by the bubbling-off of pseudo-holomorphic discs in the moduli space of connecting orbits. We started a systematic study of the moduli spaces of pseudo-holomorphic discs with Lagrangian boundary condition and formulated the obstructions in terms of the Mauer-Cartan equation on the filtered $A_\infty$-algebra associated to the Lagrangian submanifold [6]. In order to give consistent orientations on the moduli spaces, we introduced the
notion of relative spin structure and considered relative spin Lagrangian submanifolds. For a relative spin pair \((L_0, L_1)\) of Lagrangian submanifolds, we constructed a filtered \(A_\infty\)-bimodule over the \(A_\infty\)-algebras associated to \(L_0\) and \(L_1\). If each \(L_i\), \(i = 0, 1\), admits a solution \(b_i\) of the Maurer-Cartan equation, we can rectify the Floer operator to obtain a coboundary operator \(\delta^{b_0,b_1}\). Hence the Floer complex \((CF(L_0, L_1), \delta^{b_0,b_1})\) is obtained. We also considered the case that the Lagrangian submanifolds admit solutions of the Maurer-Cartan equation modulo multiples of the fundamental class \([L_i]\) (weak solution). For a weak solution \(b_i\), we assign the potential \(PO(b_i)\). If \(PO(b_0) = PO(b_1)\), we can construct the Floer complex \((CF(L_0, L_1), \delta^{b_0,b_1})\) deformed by \(b_0, b_1\). This extension with the weak bounding cochains plays crucial role in our study of Floer theory on compact toric manifolds [7].

We firstly constructed the filtered \(A_\infty\)-algebra mentioned above on suitable subcomplex of the singular cochain complex of \(L_i\) using systematic multi-valued perturbation of Kuranshi maps describing the moduli spaces. We briefly review these constructions in subsequent section. Thus the resulting filtered \(A_\infty\)-algebra depends on various choices, i.e., the choice of the subcomplex, the choice of systematic multi-valued perturbation, etc. In order to make the construction canonical, we introduced the notion of the canonical model. Since the structure constants of the filtered \(A_\infty\)-algebra depends on these choices, it is appropriate to work with the canonical model when we make practical computation of the structure constants. When we consider \(PO(b)\) as a function on the set of weak solutions of the Maurer-Cartan equation, we call it the potential function. The canonical model provides an appropriate domain of the definition of the potential function. The canonical models also play a role in the convergence of a certain spectral sequence, see Chapter 6 in [6]. (In [5], we used another kind of finitely generated complex to ensure the weak finiteness property of the filtered \(A_\infty\) algebras.) It may be also worth mentioning that we rely on canonical models in some places in [6], since the degree of the ordinary cohomology is bounded, though the degree of the singular complex is not bounded above.

We also developed an algebraic theory for filtered \(A_\infty\)-algebras, bimodules, in particular, the homotopy theory of the filtered \(A_\infty\)-algebras, bimodules and proved that the homotopy type of the resulting algebraic object does not depend on such choices. We can also reduce the filtered \(A_\infty\)-structure to appropriate free subcomplexes of the original complex. In particular, if we work over the ground coefficient field, we obtain the filtered \(A_\infty\)-structure on the classical \((co)homology of the complex. In this note, we review the construction of the canonical models of filtered \(A_\infty\)-algebras and filtered \(A_\infty\)-bimodules and explain its implication in a geometric setting.

In section 5, we induce the filtered \(A_\infty\)-algebra structure on Morse complex based on the argument in the construction of canonical models. We choose a Morse function \(f\) on \(L\), which is adapted to a triangulation of \(L\) (see section 5).

**Theorem 5.1** Let \(L\) be a relatively spin Lagrangian submanifold in a closed symplectic manifold \((M, \omega)\) and \(f\) a Morse function on \(L\) as above. Then Morse complex \(CM^\ast(f) \otimes \Lambda_\text{nov}\) carries a structure of a filtered \(A_\infty\)-algebra, which is homotopy equivalent to the filtered \(A_\infty\)-algebra associated to \(L\) constructed in [6].

This note is based on the lecture at Yashafest and we thank the organizers for the invitation.
2. Filtered $A_\infty$-algebras, bimodules

In this subsection, we recall the definition of (filtered) $A_\infty$-algebras, bimodules, homomorphisms and prepare necessary notations. Then we explain the notion of homotopy between (filtered) $A_\infty$-homomorphisms. In fact, the notion of homotopy between $A_\infty$-homomorphisms can be found in the literature, e.g., [13]. For differential graded algebras, homotopy theory was studied in rational homotopy theory, see [16], [9]. In order to make clear the relation among such notions, we introduced the notion of the model of $[0, 1] \times C$ for a (filtered) $A_\infty$-algebra $C$ and defined the notion of homotopy using such a model.

2.1) Unfiltered $A_\infty$-algebras, homomorphisms, bimodules, bimodule homomorphisms.

Let $R$ be a commutative ring, e.g., $\mathbb{Z}, \mathbb{Q}$. Let $C^*$ be a cochain complex over $R$. We assume that $C^k = 0$ for $k < 0$. Denote by $m_1$ its differential. Set $C[1]^k = C^k+1$ and denote the shifted degree by $\deg x = \deg x - 1$, where $\deg$ is the original degree of $C^*$. In this section, we use only shifted degrees. Consider a series of $k$-ary operations, $k = 1, 2, \ldots$,

$$m_k : (C[1]^*)^k \to C[1]^*$$

of degree 1 with respect to the shifted degrees.

Before giving the definition of $A_\infty$-algebras, we explain the case of differential graded algebras. Let $(C^*, d, \cdot)$ be a differential graded algebra. Define $m_1(x) = (-1)^{\deg x} \cdot d a$ and $m_2(x \otimes y) = (-1)^{\deg x \cdot (\deg y + 1)} x \cdot y$. Then we find that

$$m_1 \circ m_1(x) = 0,$$

$$m_1 \circ m_2(x \otimes y) + m_2(m_1(x_1) \otimes x_2) + (-1)^{\deg x_1} m_2(x_1 \otimes m_1(x_2)) = 0,$$

$$m_2(m_2(x_1 \otimes x_2) \otimes x_3) + (-1)^{\deg x_1} m_2(x_1 \otimes m_2(x_2 \otimes x_3)) = 0,$$

which follow from the facts that $d$ is a differential, the multiplication and the differential $d$ satisfies Leibniz’ rule and the multiplication is associative.

There are some geometric situations where multiplicative structures are defined but not exactly associative. A typical example is the composition in based loop spaces. In fact, Stasheff [15] introduced the notion of $A_\infty$-structure on topological spaces in order to characterize the homotopy types of based loop spaces. He also defined the $A_\infty$-structure in algebraic setting. For instance, a multiplicative structure is said to be associative up to homotopy, if there exists $m_3 : (C[1]^*)^3 \to C[1]^*$ such that

$$m_2(m_2(x_1 \otimes x_2) \otimes x_3) + (-1)^{\deg x_1} m_2(x_1 \otimes m_2(x_2 \otimes x_3))$$

$$+ m_1 \circ m_3(x_1 \otimes x_2 \otimes x_3) + m_3(m_1(x_1) \otimes x_2 \otimes x_3)$$

$$+ (-1)^{\deg x_1} m_3(x_1 \otimes m_1(x_2) \otimes x_3) + (-1)^{\deg x_1 + \deg x_2} m_3(x_1 \otimes x_2 \otimes m_1(x_3))$$

$$= 0.$$
Note that it coincides with the relation corresponding to the associativity, if \( \overline{m}_3 = 0 \). We can continue higher homotopies in a similar way:

\[
\sum_{k_1 + k_2 = k+1} \sum_i (-1)^{\sum_{j=1}^{i-1} \deg' x_j} \overline{m}_{k_1}(x_1, \ldots, \overline{m}_{k_2}(x_i, \ldots, x_{i+k_2-1}), \ldots, x_k) = 0.
\]

Here \( k_1, k_2 \) are positive integers. For a concise description of relations among higher homotopies, we introduce the bar complex of \( C^* \), which is defined by

\[
B(C[1]^*) = \bigoplus_{k=0}^{\infty} B_k(C[1]^*), \quad B_k(C[1]^*) = \bigoplus_{m_1, \ldots, m_k} C[1]^{m_1} \otimes \cdots \otimes C[1]^{m_k},
\]

which we consider as a tensor coalgebra. The comultiplication is given by

\[
\Delta(x_1 \otimes \cdots \otimes x_k) = \sum_{i=0}^k (x_1 \otimes \cdots \otimes x_i) \otimes (x_{i+1} \otimes \cdots \otimes x_k),
\]

where \( x_1 \otimes \cdots \otimes x_i, x_{i+1} \otimes \cdots \otimes x_k \in B(C[1]^*) \) and the former with \( i = 0 \) and the latter with \( i = k \) are understood as \( 1 \in B_0(C[1]^*) \). Extend \( \overline{m}_k \) to the graded coderivation \( \overline{m}_k \) on \( B(C[1]^*) \). Namely,

\[
\overline{m}_k(x_1 \otimes \cdots \otimes x_N) \quad \overset{N-k+1}{=} \quad \sum_{i=1}^{k-1} (-1)^{\sum_{j=1}^{i-1} \deg' x_j} x_1 \otimes \cdots \otimes x_i \otimes \overline{m}_i(x_i \otimes \cdots \otimes x_{i+k-1}) \otimes x_{i+k} \otimes \cdots \otimes x_N,
\]

We call \( (\overline{C}^*, \{ \overline{m}_k \}) \) an \( A_\infty \)-algebra, if

\[
\overline{d} = \sum_k \overline{m}_k : B(C[1]^*) \to B(C[1]^*)
\]

satisfies \( \overline{d} \circ \overline{d} = 0 \). In the case that \( \overline{m}_k = 0 \) for \( k > 2 \), this condition is equivalent to the notion of differential graded algebras.

For a collection \( \{ \overline{f}_k : B_k(C[1]^*) \to \overline{C}[1]^* \}_{k=1}^{\infty} \) of degree 0, we extend it to a homomorphism as tensor coalgebras

\[
\overline{f}(x_1 \otimes \cdots \otimes x_k) = \sum_{k_1 + \cdots + k_n = k} \overline{f}_{k_1}(x_1 \otimes \cdots \otimes x_{k_1}) \otimes \cdots \otimes \overline{f}_{k_n}(x_{k+1-k_n} \otimes \cdots \otimes x_k).
\]

We call \( \{ \overline{f}_k \} \) an \( A_\infty \)-homomorphism, if \( \overline{f} \) satisfies \( \overline{d} \circ \overline{f} = \overline{f} \circ \overline{d} \).

In terms of the components \( \overline{m}_k \)'s and \( \overline{f}_k \)'s, this is equivalent to

\[
\sum_{i_1 + \cdots + i_n = n} \overline{m}_k(\overline{f}_{i_1}(x_1 \otimes \cdots \otimes x_{i_1}) \otimes \cdots \otimes \overline{f}_{i_n}(x_{i_1+\cdots+i_n+1} \otimes \cdots \otimes x_n))
\]

\[
= \sum_{j_1 + \cdots + j_n = n} \sum_{p=1}^\ell (-1)^{\sum_{i=1}^{j_1+\cdots+j_p-1} \deg' x_i} \overline{f}_{j_1}(x_1 \otimes \cdots \otimes x_{j_1}) \otimes \cdots \otimes \overline{m}_{j_p}(x_{j_1+\cdots+j_{p-1}+1} \otimes \cdots \otimes x_{j_1+\cdots+j_p}) \otimes \cdots \otimes \overline{f}_{j_n}(x_{j_1+\cdots+j_{n-1}+1} \otimes \cdots \otimes x_n)
\]
Let \((\overline{C}_i, \{\overline{\pi}^{(i)}_k\})\), \(i = 0, 1\), be \(A_\infty\)-algebras, \(D\) a graded module and \(\overline{\pi}_{k_1, k_0}: B_{k_1}(\overline{C}_1[1]^\bullet) \otimes D[1]^\bullet \otimes B_{k_0}(\overline{C}_0[1]^\bullet) \to D[1]^\bullet\) homomorphisms of degree 1. We call \((D, \{\overline{\pi}_{k_1, k_0}\})\) an \(A_\infty\)-bimodule, if
\[
\overline{d}_\pi \circ \overline{d}_\pi = 0,
\]
where \(\overline{d}_\pi\) is defined on \(B(\overline{C}_1[1]^\bullet) \otimes D[1]^\bullet \otimes B(\overline{C}_0[1]^\bullet)\) as follows:
\[
\overline{d}_\pi(x_{1,1} \otimes \cdots \otimes x_{1,k_1} \otimes y \otimes x_{0,1} \otimes \cdots \otimes x_{0,k_0}) \\
= \overline{d}^{(1)}(x_{1,1} \otimes \cdots \otimes x_{1,k_1} \otimes y \otimes x_{0,1} \otimes \cdots \otimes x_{0,k_0}) \\
+ \sum_{k_1' \leq k_1, k_0' \leq k_0} (-1)^{\deg' x} x_{1,1} \otimes \cdots \otimes x_{1,k_1} \otimes y \otimes x_{0,1} \otimes \cdots \otimes x_{0,k_0} \\
\otimes \overline{\pi}^{(i)}_{k_1', k_0'}(x_{1,k_1} \otimes k_1' + 1 \otimes \cdots \otimes x_{1,k_1} \otimes y \otimes x_{0,1} \otimes \cdots \otimes x_{0,k_0'} \otimes x_{0,k_0+1} \otimes \cdots \otimes x_{0,k_0}) \\
+ (-1)^{\deg' + \deg' y} \overline{d}^{(0)}(x_{1,1} \otimes \cdots \otimes x_{1,k_1} \otimes y \otimes d)(x_{1,1} \otimes \cdots \otimes x_{0,k_0}).
\]
The condition for \((D, \{\overline{\pi}_{k_1, k_0}\})\) to be an \(A_\infty\)-bimodules over \(\overline{C}_i, i = 0, 1\) is equivalent to the identity
\[
\overline{d}^{(1)}(x_{1,1} \otimes \cdots \otimes x_{1,k_1} \otimes y \otimes x_{0,1} \otimes \cdots \otimes x_{0,k_0}) \\
+ \sum_{k_1' \leq k_1, k_0' \leq k_0} (-1)^{\deg' x} x_{1,1} \otimes \cdots \otimes x_{1,k_1} \otimes y \otimes x_{0,1} \otimes \cdots \otimes x_{0,k_0} \\
\otimes \overline{\pi}^{(i)}_{k_1', k_0'}(x_{1,k_1} \otimes k_1' + 1 \otimes \cdots \otimes x_{1,k_1} \otimes y \otimes x_{0,1} \otimes x_{0,k_0'} \otimes x_{0,k_0+1} \otimes \cdots \otimes x_{0,k_0}) \\
+ (-1)^{\deg' x} + \deg' y \overline{d}^{(0)}(x_{1,1} \otimes \cdots \otimes x_{1,k_1} \otimes y \otimes d)(x_{1,1} \otimes \cdots \otimes x_{0,k_0}) \\
= 0.
\]
Here \(\overline{\pi}^{(i)}_{k_1, k_0}: B(\overline{C}_1[1]^\bullet) \otimes D[1]^\bullet \otimes B(\overline{C}_0[1]^\bullet) \to D[1]^\bullet\) is defined to be \(\overline{\pi}_{k_1, k_0}\) on \(B_{k_1}(\overline{C}_1[1]^\bullet) \otimes D[1]^\bullet \otimes B_{k_0}(\overline{C}_0[1]^\bullet)\).
Let \(\{\overline{\phi}^{(i)}_{k_1, k_0}\}: \overline{C}_i[1]^\bullet \to \overline{C}_i[1]^\bullet\), \(i = 0, 1\), be \(A_\infty\)-homomorphisms and \(D\), resp. \(D'\) an \(A_\infty\)-bimodules over \(\overline{C}_i\), resp. \(\overline{C}_i', i = 0, 1\). For a collection \(\{\overline{\phi}_{k_1, k_0}\}: B_{k_1}(\overline{C}_1[1]^\bullet) \otimes D[1]^\bullet \otimes B_{k_0}(\overline{C}_0[1]^\bullet) \to D'[1]^\bullet\) of degree 0, we define
\[
\overline{\phi}: B(\overline{C}_1[1]^\bullet) \otimes D[1]^\bullet \otimes B(\overline{C}_0[1]^\bullet) \to B(\overline{C}_1'[1]^\bullet) \otimes D'[1]^\bullet \otimes B(\overline{C}_0'[1]^\bullet)
\]
as the homomorphism determined by \(\{\overline{\phi}^{(i)}_{k_1, k_0}\}, i = 0, 1\) and \(\overline{\phi}_{k_1, k_0}\). We call \(\{\overline{\phi}_{k_1, k_0}\}\) a homomorphism of \(A_\infty\)-bimodules, if
\[
\overline{d}_\pi \circ \overline{\phi} = \overline{\phi} \circ \overline{d}_\pi.
\]
2.2) The universal Novikov ring and the energy filtration.
To explain the notion of filtered $A_\infty$-algebras, we introduce the universal Novikov ring. Let $e$ and $T$ be formal variables of degree 2 and 0, respectively. Set
\[
\Lambda_{\text{nov}} = \left\{ \sum_i a_i e^\mu_i T^{\lambda_i} \mid a_i \in R, \ \mu_i \in \mathbb{Z}, \ \lambda_i \in \mathbb{R}, \ \lambda_i \to +\infty (i \to +\infty) \right\}
\]
\[
\Lambda_{0,\text{nov}} = \left\{ \sum_i a_i e^\mu_i T^{\lambda_i} \in \Lambda_{\text{nov}} \mid \lambda_i \geq 0 \right\}.
\]
Set
\[
C^* = \left\{ \sum_i c_i e^\mu_i T^{\lambda_i} \mid c_i \in \mathbb{C}, \ \mu_i \in \mathbb{Z}, \ \lambda_i \in \mathbb{R}, \ \lambda_i \to +\infty (i \to +\infty) \right\},
\]
which is the completion of the graded tensor product $\mathbb{C} \otimes_R \Lambda_{0,\text{nov}}$, with respect to the energy filtration given below. We define the filtration defined by
\[
F^\lambda C^* = \left\{ \sum_i x_i e^\mu_i T^{\lambda_i} \in C^* \mid x_i \in \mathbb{C}, \ \lambda_i \geq \lambda \right\}
\]
on $C^*$ and denote by $F^\lambda (C[1]^{m_1} \otimes \ldots \otimes C[1]^{m_k})$ the submodule of $C[1]^{m_1} \otimes \ldots \otimes C[1]^{m_k}$ spanned by
\[
F^\lambda_i (C[1]^{m_1}) \otimes \ldots \otimes F^\lambda_k (C[1]^{m_k}), \quad \sum_{i=1}^k \lambda_i = \lambda.
\]
Define the bar complex of $C[1]^*$ by the completion with respect to the energy filtration and denote it by $B_{k}(C[1]^*)$.

2.3 Filtered case and G-gapped conditions.
Consider the $k$-ary operations, $k = 0, 1, 2, \ldots,$
\[
m_k : B_k(C[1]^*) \to C[1]^*
\]
such that
\[
m_k(F^{\lambda_1} C[1]^* \otimes \ldots \otimes F^{\lambda_k} C[1]^*) \subset F^{\lambda_1 + \ldots + \lambda_k} C[1]^*
\]
and
\[
m_0(1) \in F^{\lambda'} C[1]^* \text{ for some } \lambda' > 0.
\]
We used the induction on the energy level in various arguments in [3], see also section 3 in this note. For such purposes, we introduced the G-gapped condition, which we assume from now on, as follows. Note that the G-gapped condition follows from Gromov’s compactness theorem in the case of symplectic Floer theory. Let $G \subset \mathbb{R}_{\geq 0} \times 2\mathbb{Z}$ be a monoid such that $pr_i^{-1}([0,c])$ is finite for any $c \geq 0$ and $pr_i^{-1}(0) = \{0 = (0,0)\}$.
Here $pr_i$ is the projection to the $i$-th factor, $i = 1, 2$. The filtered $A_\infty$-algebra is said to be $G$-gapped, if there exist
\[
m_{k,\beta_i} : B_k(C[1]^*) \to \mathbb{C}[1]^*
\]
for $\beta_i = (\lambda_i, \mu_i) \in G \subset \mathbb{R}_{\geq 0} \times 2\mathbb{Z}$ such that $m_{0,0} = 0$ and
\[
m_k = \sum_i T^{\lambda_i} e^{\mu_i/2} m_{k,\beta_i}.
\]
Extend $m_k$ to the graded coderivation $\hat{m}_k$ on $B(C[1]^*)$. We call $(C^*, \{m_k\})$ a filtered $A_\infty$-algebra, if
\[
\hat{d} = \sum_k \hat{m}_k : B(C[1]^*) \to B(C[1]^*)
\]
Here $k_1$ is a positive integer and $k_2$ is a non-negative integers. When $k_2 = 0$, $m_{k_2}(x_1, \ldots, x_{i+k_2-1})$ is understood as $m_0(1)$.

For a filtered $A_\infty$-algebra $(C^\bullet, \{m_k\})$, set $\overline{m}_k = m_{k,0}, 0 = (0,0) \in \mathbb{R}_{>0} \times 2\mathbb{Z}$.

Then $(C^\bullet, \{\overline{m}_k\})$ is an $A_\infty$-algebra. We call $(C^\bullet, \{m_k\})$ a deformation of $(C^\bullet, \{\overline{m}_k\})$.

Note that $m_1 \circ m_1$ may not be zero and we have

$$m_1 \circ m_1(x) + m_2(m_0(1), x) + (-1)^{\deg x} m_2(x, m_0(1)) = 0.$$  

We set

$$e^b = 1 + b \otimes b \otimes b + b \otimes b \otimes b + \ldots,$$

for $b \in F^\lambda(C[1]^n)$ with $\lambda > 0$ and consider the Maurer-Cartan equation:

$$\hat{d}(e^b) = 0,$$

which is equivalent to

$$m_0(1) + m_1(b) + m_2(b, b) + m_3(b, b, b) + \cdots = 0.$$  

For a given $b$, we define a coalgebra homomorphism

$$\Phi^b(x_1 \otimes x_2 \otimes \cdots \otimes x_k) = e^b \otimes x_1 \otimes e^b \otimes x_2 \otimes e^b \otimes \cdots \otimes e^b \otimes x_k \otimes e^b.$$  

Then define

$$m^b_\bullet(x_1 \otimes \cdots \otimes x_k) = m_\bullet \circ \Phi^b(x_1 \otimes \cdots \otimes x_k),$$

where $m_\bullet : B(C[1]^\bullet) \to C[1]^\bullet$ is defined by $m_\bullet|_{B_0(C[1]^\bullet)} = m_k$. Then, for a solution $b$ of the Maurer-Cartan equation, we find that $m^b_0(1) = 0$, hence $m^b_1 \circ m^b_1 = 0$.

Namely, the original $m_1$ is rectified to a coboundary operator $m^b_1$ using a solution of the Maurer-Cartan equation, which we also call a bounding cochain.

For a collection $\{f_k : B_k(C[1]^\bullet) \to C'[1]^\bullet\}_{k=0}^\infty$ of degree 0, we define

$$\hat{f}(x_1 \otimes \cdots \otimes x_k) = \sum_{k_1 + \cdots + k_n = k} f_{k_1}(x_1 \otimes \cdots \otimes x_{k_1}) \otimes \cdots \otimes f_{k_n}(x_{k+1-k_n} \otimes \cdots \otimes x_k),$$

for $k > 0$ and

$$\hat{f}(1) = 1 + f_0(1) + f_0(1) \otimes f_0(1) + \cdots,$$

where $1 \in \Lambda_{0,non} = B_0(C[1]^\bullet)$. We assume the $G$-gapped condition, i.e., there exist

$$f_{k,\beta} : B_k(\overline{C}[1]^\bullet) \to \overline{C}[1]^\bullet$$

for $\beta = (\lambda_i, \mu_i) \in G$ with $\lambda_i \to +\infty$ as $i \to +\infty$ such that

$$f_k = \sum_i T^{\lambda_i} e^{\mu_i/2} f_{k,\beta_i}.$$  

In particular, $\hat{f}$ preserves the energy filtration. Namely,

$$\hat{f}(F^\lambda B(C[1]^\bullet)) \subset F^\lambda C'[1]^\bullet,$$

where $\{F^\lambda B(C[1]^\bullet)\}$ is the filtration derived from the filtration $F^\lambda$ on $C[1]^\bullet$. We call $\{f_k\}$ a $G$-gapped filtered $A_\infty$-homomorphism, if $\hat{d}_C \circ \hat{f} = \hat{f} \circ \hat{d}_C$. When we do not specify the monoid $G$, we call gapped filtered $A_\infty$-algebras, gapped filtered $A_\infty$-homomorphisms, etc.

2.4) Homotopy theory.
In [6], we introduced the notion of models of \([0,1] \times C^*\) (Definition 15.1) and gave two constructions. Using this notion, we developed the homotopy theory of filtered \(A_\infty\)-algebras and filtered-\(A_\infty\) bimodules. Our formulation has an advantage to clarify equivalence of various definitions of homotopy of \(A_\infty\) algebras appearing in the literature even for the unfiltered cases.

Let \(C\) be the completion of \(\overline{C} \otimes \Lambda_0\), which is a filtered \(A_\infty\)-algebra.

**Definition 2.1.** Let \(\mathcal{E}\) be the completion of \(\overline{C} \otimes \Lambda_0\), which is a filtered \(A_\infty\)-algebra together with filtered \(A_\infty\)-homomorphisms.

\[
\text{Incl}: C \rightarrow \mathcal{E}, \text{Eval}_{s=1}: \mathcal{E} \rightarrow C, i = 0, 1.
\]

We call \(\mathcal{E}\) a model of \([0,1] \times C\), if the following conditions are satisfied:

- \(\text{Incl}_{k,\beta}\) and \(\text{Eval}_{s=1}\), \(i = 0, 1\) are zero unless \((k, \beta) = (1, \beta_0)\).
- \(\text{Incl}_{1,\beta_0}, (\text{Eval}_{s=0})_{1,\beta_0}\) are cochain homotopy equivalences between \(\overline{C}\) and \(\overline{\mathcal{E}}\).
- \(\text{Eval}_{s=0} \circ \text{Incl} = \text{Eval}_{s=1} \circ \text{Incl} = \text{id}\).
- \(\text{Eval}_{s=0} \oplus \text{Eval}_{s=1}: \mathcal{E} \rightarrow C \oplus C\) is surjective.

We quote here one of constructions of the models of \([0,1] \times C\) for reader’s convenience.

Set

\[
C^{[0,1]} = C \oplus C[-1] \oplus C,
\]

and define \(\mathcal{J}_0, \mathcal{J}_1: C \rightarrow C^{[0,1]}\) of degree 0 and \(\mathcal{J}: C \rightarrow C^{[0,1]}\) of degree 1 by

\[
\mathcal{J}_0(x) = (x, 0, 0), \mathcal{J}_1(x) = (0, 0, x), \mathcal{J}_1(x) = (0, x, 0).
\]

We extend \(\mathcal{J}_0, \mathcal{J}_1\) to \(B(C[1]) \rightarrow B(C^{[0,1]}[1])\) and denote them by the same symbol. Define

\[
(\text{Eval}_{s=0})_1(x, y, z) = x, \ (\text{Eval}_{s=1})_1(x, y, z) = z,
\]

\[
(\text{Incl})_1(x) = \mathcal{J}_0(x) + \mathcal{J}_1(x) = (x, 0, x).
\]

We define the filtered \(A_\infty\)-structure \(\{\mathcal{M}_k\}\).

For \(\mathcal{M}_0, \mathcal{M}_1\), we set

\[
\mathcal{M}_0(1) = (\text{Incl})_1(m_0(1)),
\]

\[
\mathcal{M}_1(\mathcal{J}_0(x)) = \mathcal{J}_0(m_1(x)) + (-1)^{deg' x} \mathcal{J}(x),
\]

\[
\mathcal{M}_1(\mathcal{J}_1(x)) = \mathcal{J}_1(m_1(x)) - (-1)^{deg' x} \mathcal{J}(x),
\]

\[
\mathcal{M}_1(\mathcal{J}(x)) = \mathcal{J}(m_1(x)).
\]

We define \(\mathcal{M}_k, k \geq 2\) as follows. For \(x \in B_k(C[1]), y \in C\) and \(z \in B_\ell(C[1]),\) we set

\[
\mathcal{M}_{k+\ell+1}(\mathcal{J}_0(x), \mathcal{J}(y), \mathcal{J}_1(z)) = (-1)^{deg' y} \mathcal{J}(m_{k+\ell+1}(x, y, z)),
\]

and

\[
\mathcal{M}_k(\mathcal{J}_0(x)) = \mathcal{J}_0(m_k(x)), \mathcal{M}_\ell(\mathcal{J}_1(z)) = \mathcal{J}_1(m_\ell(z)), \text{ for } k, \ell \geq 2.
\]

Here the order of \(\mathcal{J}_0(x), \mathcal{J}(y), \mathcal{J}_1(z)\) is important. We define operators \(\mathcal{M}_k\) on \(C^{[0,1]}\) other than those defined above to be zero.

Models of \([0,1] \times C\) are not unique, but we proved the following:
**Theorem 2.1** (Theorem 15.34 in [6]). Let $C_1, C_2$ be gapped filtered $A_\infty$-algebras and $\mathcal{C}_1, \mathcal{C}_2$ any models for $[0, 1] \times C_1, [0, 1] \times C_2$, respectively. Let $\mathcal{f}: C_1 \rightarrow C_2$ be a gapped filtered $A_\infty$-homomorphism. Then there exists a gapped filtered $A_\infty$-homomorphism $\mathcal{g}: \mathcal{C}_1 \rightarrow \mathcal{C}_2$ such that

$$\text{Eval}_{s=s_0} \circ \mathcal{g} = \mathcal{f} \circ \text{Eval}_{s=s_0}, \ s_0 = 0, 1$$

and

$$\text{Incl} \circ \mathcal{f} = \mathcal{g} \circ \text{Incl}.$$  

We define two filtered $A_\infty$-homomorphisms $f_i : C_1 \rightarrow C_2, i = 0, 1$ are homotopic, if there is a model $\mathcal{C}_2$ of $C_2$ and a filtered $A_\infty$-homomorphism $\mathcal{g}: C_1 \rightarrow \mathcal{C}_2$ such that $f_i = \text{Eval}_{s=s_i} \circ \mathcal{g}$. Although the definition literally depends on the choice of the model $\mathcal{C}_2$, we can show that the notion of homotopy between $f_i$ does not depend on the choice of the model and the homotopy is, in fact, an equivalence relation, see Chapter 4 in [6].

Note that the notion of homotopy between $A_\infty$-homomorphisms in the unfiltered case appeared in literature, e.g., [14]. By taking a suitable model, we can find that our definition above coincides with such a definition. It also implies that various definitions which appear in the literature are equivalent to one another. We think that the notion of models clarifies arguments and is also useful when we consider the gauge equivalence between solutions of the Maurer-Cartan equation. Namely, two solutions $b, b'$ of the Maurer-Cartan equation is gauge equivalent, if there is a model $\mathcal{C}$ of $[0, 1] \times C$ and a solution $\tilde{b}$ of the Maurer-Cartan equation on $\mathcal{C}$ such that $\text{Eval}_{s=0}(\tilde{b}) = b$ and $\text{Eval}_{s=1}(\tilde{b}) = b'$. For details, see section 16 in [6].

Among other things, we proved the Whitehead type theorem as follows. An $A_\infty$-homomorphism $\{f_i\}$ from $\overline{C}^\bullet$ to $\overline{C}'^\bullet$ is called a weak homotopy equivalence, if $\overline{f}_1 : \overline{C}^\bullet \rightarrow \overline{C}'^\bullet$ is a cochain homotopy equivalence between $m_1$-complexes. A filtered $A_\infty$-homomorphism $\{f_k\}$ from $C^1[1]^\bullet$ to $C'[1]^\bullet$ is called a weak homotopy equivalence, if $\overline{f}_1 = f_{1, 0}$ is a cochain homotopy equivalence between $m_1 = m_{1, 0}$-complexes.

**Theorem 2.2** (Theorem 15.45 in [6]). (1) A weak homotopy equivalence of $A_\infty$-algebras is a homotopy equivalence.

(2) A gapped weak homotopy equivalence between gapped filtered $A_\infty$-algebras is a homotopy equivalence. The homotopy inverse of a strict weak homotopy equivalence can be taken to be strict.

Note that the above theorem does not hold in the realm of differential graded algebras. The notion of $A_\infty$-homomorphism is much wider than that of homomorphisms as differential graded algebras.

**2.5) Filtered $A_\infty$-bimodules.**

Let $(C_i^\bullet, \{m_k^{(i)}\}), i = 0, 1$, be filtered $A_\infty$-algebras and $D^\bullet$ a graded module. Write

$$D[1]^\bullet = \overline{D}[1]^\bullet \otimes \Lambda_{0, \text{nov}}$$

and

$$\overline{D}[1]^\bullet = \overline{\text{D}}[1]^\bullet \otimes \Lambda_{\text{nov}}.$$  

Let $n_{k_1, k_0} : B_{k_1}(C_1[1]^\bullet) \otimes D[1]^\bullet \otimes B_{k_0}(C_0[1]^\bullet) \rightarrow D[1]^\bullet$, $k_1, k_0 = 0, 1, 2, \ldots$, be $\Lambda_{0, \text{nov}}$-module homomorphisms of degree 1. We also denote its extension to $\overline{D}[1]^\bullet$...
by the same symbol \( n_{k_1, k_0} \). We call \((D^\bullet, \{n_{k_1, k_0}\})\) and \((\bar{D}^\bullet, \{n_{k_1, k_0}\})\) a filtered \(A_\infty\)-bimodule over \((C^\bullet_1, \{m_0^1\})\), if

\[
\hat{d}_n \circ \hat{d}_n = 0,
\]

where \(\hat{d}_n\) is the coderivation on \(B(C_1[1]^\bullet) \otimes D[1]^\bullet \otimes B(C_0[1]^\bullet)\) determined by \(\{m_0^{(i)}\}\), \(i = 0, 1\), and \(\{n_{k_1, k_0}\}\). The G-gapped condition is defined in a similar way to the case of filtered \(A_\infty\)-algebras:

\[
n_{k_1, k_0} = \sum_{\beta \in G} T^{pr_1(\beta)} e^{pr_2(\beta)/2} n_{k_1, k_0, \beta},
\]

where

\[
n_{k_1, k_0, \beta} : B_{k_1}(\overline{C_1[1]^\bullet}) \otimes \overline{D[1]^\bullet} \otimes B_{k_0}(\overline{C_0[1]^\bullet}) \to \overline{D[1]^\bullet}.
\]

For \(\lambda \in \mathbb{R}\), we set

\[
F^\lambda \bar{D}^\bullet = T^\lambda \cdot D^\bullet.
\]

For \(\lambda \geq 0\), \(F^\lambda \bar{D}^\bullet \subset D^\bullet\), hence we obtain a filtration on \(D^\bullet\). It is clear that

\[
\hat{d}_n(F^\lambda B(C_1[1]^\bullet) \otimes F^\lambda \bar{D}^\bullet \otimes F^\lambda B(C_0[1]^\bullet)) \subset F^\lambda_1 + \lambda_2 + \lambda_3 \bar{D}[1]^\bullet.
\]

Note that \(n_{0, 0} \circ n_{0, 0}\) may not be zero and we have

\[
n_{0, 0} \circ n_{0, 0}(y) + n_{1, 0}(m_0^{(1)}(1), y) + (-1)^{\deg y} n_{0, 1}(y, m_0^{(0)}(1)) = 0.
\]

For \(b_i \in \mathfrak{s}^{\lambda(i)}(C_1^\bullet)\) with \(\lambda^{(i)} > 0\), we define

\[
n_{b_0, b_1}^{b_0, b_1}(x \otimes y \otimes z) = n_{s, s}(\Phi^{b_1}(x) \otimes y \otimes \Phi^{b_0}(z)),
\]

for \(x \in B_{k_1}(C_1[1]^\bullet)\) and \(z \in B_{k_0}(C_0[1]^\bullet)\). In particular,

\[
n_{b_0, b_1}^{b_0, b_1}(y) = n_{s, s}(e^{b_1} \otimes y \otimes e^{b_0}).
\]

If \(b_0, b_1\) are solutions of the Maurer-Cartan equations in the filtered \(A_\infty\)-algebras \(C_0, C_1\), respectively, we find that

\[
n_{b_0, b_1}^{b_0, b_1} \circ n_{b_0, b_1}^{b_0, b_1} = 0.
\]

Namely, we can rectify the original \(n_{0, 0}\) to a coboundary operator \(n_{b_0, b_1}^{b_0, b_1}\) on \(D[1]\).

Let \(\{f_k^{(i)}\}, i = 0, 1\), be filtered \(A_\infty\)-homomorphisms from \(C^\bullet_e\) to \(C^\bullet_e\) and \((\bar{D}^\bullet, \{n_{k_1, k_0}\})\), resp. \((\bar{D}^\bullet, \{n_{k_1, k_0}\})\), filtered \(A_\infty\)-bimodules over \((C^\bullet_1, \{m_0^{(i)}\})\), resp. \((C^\bullet_1, \{m_0^{(i)}\})\). Suppose that there exist a real number \(c\) and \(\Lambda_{nov}\)-homomorphisms \(\phi_{k_1, k_0} : B_{k_1}(C_1[1]^\bullet) \otimes \bar{D}[1]^\bullet \otimes B_{k_0}(C_0[1]^\bullet) \to \bar{D}'[1]^\bullet, k_1, k_0 = 0, 1, 2, \ldots, \), such that

\[
\phi_{k_1, k_0}(F^\lambda B_{k_1}(C_1[1]^\bullet) \otimes F^\lambda \bar{D}[1]^\bullet \otimes F^\lambda B_{k_0}(C_0[1]^\bullet)) \subset F^\lambda_1 + \lambda_2 + \lambda_3 - c \bar{D}'[1]^\bullet.
\]

We call such \(c\) the energy loss of \(\{\phi_{k_1, k_0}\}\). For such a collection \(\{\phi_{k_1, k_0}\}\), we define

\[
\hat{\phi} : B(C_1[1]^\bullet) \otimes \bar{D}[1]^\bullet \otimes B(C_0[1]^\bullet) \to B(C_1[1]^\bullet) \otimes \bar{D}'[1]^\bullet \otimes B(C_0[1]^\bullet)
\]

as the homomorphism determined by \(\{f_k^{(i)}\}, i = 0, 1\), and \(\{\phi_{k_1, k_0}\}\). We call \(\phi = \{\phi_{k_1, k_0}\}\) a weakly filtered \(A_\infty\)-homomorphism of filtered \(A_\infty\)-bimodules, if

\[
\hat{d}_n \circ \hat{\phi} = \hat{\phi} \circ \hat{d}_n,
\]

when we can take \(c = 0\), \(\phi = \{\phi_{k_1, k_0}\}\) is called a filtered \(A_\infty\)-homomorphism. Suppose that \(C^\bullet_1, C^\bullet_e\) are \(G\)-gapped. Let \(G' \subset \mathbb{R} \times 2\mathbb{Z}\) be a \(G\)-set such that
$\text{pr}_1^{-1}([(-\infty, \lambda)]]$ is finite for any $\lambda \in \mathbb{R}$ and $\text{pr}_1(G)$ is bounded from below. We say that $\phi = \{\phi_{k_0}, k_0\}$ is $G'$-gapped, if

$$\phi_{k_0, k_0} = \sum_{\beta' \in G'} T^{pr_1(\beta')} e^{pr_2(\beta')/2} \phi_{k_0, k_0, \beta'}$$

where

$$\phi_{k_0, k_0, \beta'} : B_{k_0}(\overline{C}_1[1] \otimes \overline{D}[1] \otimes B_{k_0}(\overline{C}_0[1]) \to \overline{D}[1]$$

The homotopy theory between filtered $A_{\infty}$-homomorphisms of filtered $A_{\infty}$-bimodules is also developed in [6].

We also proved the Whitehead theorem for (filtered) $A_{\infty}$-bimodules.

**Theorem 2.3** (Theorem 21.35 [5]). Let $\phi : D^\bullet \to D'^\bullet$ be a gapped filtered $A_{\infty}$-bimodule homomorphism over $(\{f^{(1)}, f^{(0)}\}$, where $f^{(1)} : C_* \to C'_{*}$ are homotopy equivalences. Suppose that $\phi_{(0,0,0)}$ is a chain homotopy equivalence. Then $\phi$ is a homotopy equivalence of filtered $A_{\infty}$-bimodules.

**Remark 2.1.** Here we require $\phi$ is a filtered $A_{\infty}$-homomorphism. Since a weakly filtered $A_{\infty}$-homomorphism, $\phi_{(0,0,0)}$ may not induce a chain map with respect to $n_{0,0,0}$ and $n'_{0,0,0}$.

### 2.6) Filtered $A_{n,K}$ structure.

For a later argument in section 4, we recall the notion of filtered $A_{n,K}$-algebras. Let $G \subset \mathbb{R}_{\geq 0} \times 2\mathbb{Z}$ be a monoid as above and $\beta_0 = 0 \in G$. For $\beta \in G$, we define

$$\| \beta \| = \begin{cases} \sup \{n \mid \exists \beta_i \in G \setminus \{\beta_0\}, \sum_{i=1}^{n} \beta_i = \beta \} + |pr_1(\beta)| - 1 & \text{if } \beta \neq \beta_0, \\ -1 & \text{if } \beta = \beta_0. \end{cases}$$

Then we introduce a partial order on $(G \times \mathbb{Z}_{\geq 0}) \setminus \{(\beta_0, 0)\}$ by $(\beta_1, k_1) \succ (\beta_2, k_2)$ if and only if either

$$\| \beta_1 \| + k_1 > \| \beta_2 \| + k_2$$

or

$$\| \beta_1 \| + k_1 = \| \beta_2 \| + k_2, \text{ and } \| \beta_1 \| = \| \beta_2 \|.$$ 

We write $(\beta_1, k_1) \sim (\beta_2, k_2)$, when

$$\| \beta_1 \| + k_1 = \| \beta_2 \| + k_2, \text{ and } \| \beta_1 \| = \| \beta_2 \|.$$ 

We define $(\beta_1, k_1) \succeq (\beta_2, k_2)$ if either $(\beta_1, k_1) \succ (\beta_2, k_2)$ or $(\beta_1, k_1) \sim (\beta_2, k_2)$.

We also write $(\beta, k) \prec (n', k')$, when $\| \beta \| + k < n' + k'$ or $\| \beta \| + k = n' + k'$ and $\| \beta \| < n'$.

Let $C^*$ be a cochain complex over $R$ and $C^* = C^* \otimes \Lambda_{0,nov}$. Suppose that there are

$$m_{k, \beta} : B(C_1[1]) \to C_1[1]$$

for $(\beta, k) \in (G \times \mathbb{Z}) \setminus \{(\beta_0, 0)\}$ with $(\beta, k) \prec (n, K)$. We also suppose that $m_{1, \beta_0}$ is the boundary operator of the cochain complex $C^*$. We call $(C^*, \{m_{k, \beta}\})$ a $G$-gapped filtered $A_{n,K}$-algebra, if the following holds

$$\sum_{\beta_1 + \beta_2 = k, k_1 + k_2 = k + 1} \sum_i (-1)^{\deg x_i^{(1)}} m_{k_2, \beta_2}(x_i^{(1)}, m_{k_1, \beta_1}(x_i^{(2)}), x_i^{(3)}) = 0$$

for all $(\beta, k) \prec (n, K)$, where

$$\Delta^2(x) = \sum_i x_i^{(1)} \otimes x_i^{(2)} \otimes x_i^{(3)}.$$
Here $\Delta$ is the coproduct of the tensor coalgebra.

We also have the notion of filtered $A_{n,K}$-homomorphisms, filtered $A_{n,K}$-homotopy equivalences in a natural way. In [9], we proved the following:

**Theorem 2.4** (Theorem 30.72 in [6]). Let $C_1^\bullet$ be a filtered $A_{n,K}$-algebra and $C_2^\bullet$ a filtered $A_{n',K'}$-algebra such that $(n,K) \prec (n',K')$. Let $\mathfrak{h} : C_1^\bullet \rightarrow C_2^\bullet$ be a filtered $A_{n,K}$-homomorphism. Suppose that $\mathfrak{h}$ is a filtered $A_{n,K}$-homotopy equivalence. Then there exist a filtered $A_{n',K'}$-algebra structure on $C_1^\bullet$ extending the given filtered $A_{n,K}$-algebra structure and a filtered $A_{n',K'}$-homotopy equivalence $C_1^\bullet \rightarrow C_2^\bullet$ extending the given filtered $A_{n,K}$-homotopy equivalence $\mathfrak{h}$.

3. Canonical models

In this section, we give the notion of canonical models and explain their construction after section 23, Chapter 5 of [6]. The unfiltered version of such a result goes back to Kadeishvili [10]. There are two methods to construct canonical models in unfiltered case. One is based on obstruction theory due to Kadeishvili and the other uses the summation over trees due to Kontsevich and Soibelman [11]. Our argument is an adaptation of the latter argument and we also constructed the canonical models for filtered case.

When the ground coefficient ring $R$ is a field, we have the following:

**Theorem 3.1** (Theorem 23.1, Theorem 23.2 in [6]). (1) Any unfiltered $A_\infty$-algebra $(\overline{C}^\bullet, \{\overline{m}_k\})$ is homotopy equivalent to an $A_\infty$-algebra $(\overline{C}^\bullet, \{\overline{m}_k\})$ with $\overline{m}_1 = 0$.

(2) Any gapped filtered $A_\infty$-algebra $(C^\bullet, \{m_k\})$ is homotopy equivalent to a gapped filtered $A_\infty$-algebra $(C^\bullet, \{m'_k\})$ with $m'_1 = 0$. Moreover, the homotopy equivalence can be taken as a gapped $A_\infty$-homomorphism.

An $A_\infty$-algebra is called canonical, if $\overline{m}_1 = 0$. A canonical model of an $A_\infty$-algebra is a canonical $A_\infty$-algebra homotopy equivalent to the original one. The statement (1) is Kadeishvili’s theorem and implies that the $\overline{m}_1$-cohomology has a structure of an $A_\infty$-algebra. Note that, in general, we do not have $\overline{m}_1$-cohomology, since $m_1 \circ m_1$ may not be zero. A filtered $A_\infty$-algebra is called canonical, if $m_{1,0} = \overline{m}_1 = 0$. A canonical model of a filtered $A_\infty$-algebra is a canonical filtered $A_\infty$-algebra homotopy equivalent to the original one.

Pick a submodule $\mathcal{H}^* \hookrightarrow \ker \overline{m}_1 \cap \overline{C}^\bullet$ such that $\nu_* : \mathcal{H}^k \cong H^k(\overline{C}^\bullet, \overline{m}_1)$, and $\Pi^k : \overline{C}^\bullet \rightarrow \mathcal{H}^k \subset \overline{C}^\bullet$ such that $\Pi^k \circ \Pi^k = \Pi^k$ and $\Pi^k \circ \overline{m}_1 = 0$. We will construct a structure of a filtered $A_\infty$-algebra on $\mathcal{H}[1]^* \otimes \Lambda_{nov}$ and a filtered $A_\infty$-homomorphism from $\mathcal{H}[1]^* \otimes \Lambda_{nov}$ to $C[1]^*$, which is a weak homotopy equivalence. Since $R$ is a field, any cochain homomorphism inducing an isomorphism on cohomologies is a weak homotopy equivalence. Firstly, we observe the following:

**Lemma 3.2.** There exist $G^k : \overline{C}^k \rightarrow \overline{C}^{k-1}$, $k = 0, 1, \ldots, n$, such that

\begin{align*}
(1) & \quad id - \Pi^k = - (\overline{m}_1 \circ G^k + G^{k+1} \circ \overline{m}_1), \\
(2) & \quad G^k \circ G^{k+1} = 0.
\end{align*}

From now on, let $\mathcal{H}^* \hookrightarrow \overline{C}^\bullet$ be a subcomplex and $\Pi : \overline{C}^k \rightarrow \overline{C}^k$ be a projection to $\mathcal{H}^k$ such that there exist $G^k : \overline{C}^k \rightarrow \overline{C}^{k-1}$ satisfying (1), (2) in Lemma 3.2. We do not assume that $\overline{m}_1|_{\mathcal{H}} = 0$. Thus $\mathcal{H}^*$ is not necessarily isomorphic to
the cohomology \( H^\bullet(\mathcal{C}) \). But the condition (1) implies that \( \iota_* : H^\bullet(\mathcal{H}, m_1|_{\mathcal{H}}) \cong H^\bullet(\mathcal{C}^k, m_1) \). Theorem 3.1 follows from the following:

**Theorem 3.3.** (1) There exists a structure \( \{m_k\}_{k=1}^{\infty} \) of an \( A_\infty \)-algebra on \( \mathcal{H} \) with \( m'_1 = m_1|_{\mathcal{H}} \). The inclusion \( \iota \) extends to an \( A_\infty \)-homomorphism \( \{f_k\}_{k=1}^{\infty} \) with \( f_1 = \iota \).

(2) There exists a structure \( \{m_k\}_{k=0}^{\infty} \) of a filtered \( A_\infty \)-algebra on \( \mathcal{H} \otimes \Lambda_{0, nov} \). The inclusion \( \iota \) extends to a filtered \( A_\infty \)-homomorphism \( \{f\}_{k=0}^{\infty} \) with \( f_{1,0} = \iota \).

Let \( G \) be a monoid as in section 2 and \( \text{pr}_1(G) = \{\lambda(i)\} \) such that

\[
0 = \lambda(0) < \lambda(1) < \lambda(2) < \cdots \rightarrow +\infty,
\]

unless \( G = \{(0,0)\} \). We write

\[
m_{k,i} = \sum_{\beta \in G} e^{\text{pr}_1(\beta)/2} m_{k,\beta}
\]

and

\[
m_{k,i}^2 = T^{\lambda(i)} m_{k,i}.
\]

Thus \( m_k = \sum_i m_{k,i}^2 \). Here \( m_{k,i} \) is considered as

\[
m_{k,i} : B_k(\mathcal{C}[1]^*) \otimes R[e,e^{-1}] \rightarrow \mathcal{C}[1]^* \otimes R[e,e^{-1}].
\]

By an abuse of notation, we also denote by \( \Pi^k, G^k \) the extensions thereof to \( \mathcal{C}^k \otimes R[e,e^{-1}] \) as a \( R[e,e^{-1}] \)-module homomorphism.

In order to define a \( G \)-gapped filtered \( A_\infty \)-structure on \( \mathcal{H}[1]^* \otimes \Lambda_{0, nov} \) and a \( G \)-gapped \( A_\infty \)-homomorphism from \( \mathcal{H}[1]^* \otimes \Lambda_{0, nov} \) to \( C[1]^* \), we introduce some notation.

A decorated planar rooted tree is a quintet \( \Gamma = (T, i, v_0, V_{\text{lad}}, \eta) \), which consists of

- \( T \) is a tree,
- \( i : T \rightarrow D^2 \) is an embedding,
- \( v_0 \) is the root vertex,
- \( V_{\text{lad}} = \{ \text{vertices of valency 1} \} \setminus C_{\text{ext}}^0(T) \),
- \( \eta : C_{\text{int}}^0(T) = C_0^0(T) \setminus C_{\text{ext}}^0(T) \rightarrow \{ 0, 1, 2, \ldots \} \).

Here \( C_0^0(T) \) is the set of vertices of the tree \( T \), \( C_{\text{ext}}^0(T) = i^{-1}(\partial D^2) \) is the set of exterior vertices and \( C_{\text{int}}^0(T) \) is the set of interior vertices. Note that the root vertex \( v_0 \) is an exterior vertex and \( V_{\text{lad}} \subset C_{\text{int}}^0(T) \). Let \( G_k^+ \) be the set of \( \Gamma \) such that \#\( C_{\text{ext}}^0 = k \) and \( \eta(v) > 0 \) if \( v \in C_{\text{int}}^0(T) \) is a vertex of valency 1 or 2. We set \( E(\Gamma) = \sum_{v \in C_{\text{int}}^0(T)} \lambda(\eta(v)) \).

For each \( \Gamma \in G_{k+1}^+ \), we construct

\[
m_{\Gamma} : B_k(\mathcal{H}[1]^*) \otimes R[e,e^{-1}] \rightarrow \mathcal{H}[1]^* \otimes R[e,e^{-1}],
\]

which is of degree 1 and

\[
f_{\Gamma} : B_k(\mathcal{H}[1]^*) \otimes R[e,e^{-1}] \rightarrow \mathcal{C}[1]^* \otimes R[e,e^{-1}],
\]

which is of degree 0. Then we define

\[
m_k' = \sum_{\Gamma \in G_{k+1}^+} T^{E(\Gamma)} m_{\Gamma} : B_k(\mathcal{H}[1]^*) \otimes \Lambda_{0, nov} \rightarrow \mathcal{H}[1]^* \otimes \Lambda_{0, nov}.
\]
Figure 1.

and

\[ f_k = \sum_{r \in G_{k+1}} T^{E(T)} f_r : B_k(\mathcal{H}[1]^{\bullet}) \otimes \Lambda_{0,\text{nov}} \to \overline{\mathcal{C}}[1]^{\bullet} \otimes \Lambda_{0,\text{nov}}. \]

We will show that \((\mathcal{H}[1]^{\bullet} \otimes \Lambda_{0,\text{nov}}, \{m'_k\})\) is a \(G\)-gapped filtered \(A_\infty\)-algebra and \(f = \{f_k\}\) is a \(G\)-gapped \(A_\infty\)-homomorphism, which is a weak homotopy equivalence. Then the Whitehead type theorem implies that \(f\) is a homotopy equivalence.

**Step 1.** The case that \(\# C^0_{\text{int}}(T) = 0\).

Such a \(T\) consists of two exterior vertices and an edge joining them. Therefore, there is unique element \(\Gamma_0\), which belongs to \(G^2\). We define

\[ m_{\Gamma_0} = m_1|_{\mathcal{H}[1]} \]

and

\[ f_{\Gamma_0} : \mathcal{H}[1]^{\bullet} \otimes R[e, e^{-1}] \to \overline{\mathcal{C}}[1]^{\bullet} \otimes R[e, e^{-1}] \]

to be the inclusion \(i\).

**Step 2.** The case that \(\# C^0_{\text{int}}(T) = 1\).

For any \(k \geq 1\), there is a unique planar tree with \(\# C^0_{\text{ext}}(T) = k + 1\) and \(\# C^0_{\text{int}}(T) = 1\). Let \(\Gamma_{k+1} \in G_{k+1}^+\) be a decorated planar tree with one interior vertex \(v\), see Figure 1.

We define

\[ m_{\Gamma_{k+1}} = \Pi \circ m_{k, \eta(v)} : B_k(\mathcal{H}[1]^{\bullet}) \otimes R[e, e^{-1}] \to \mathcal{H}[1]^{\bullet} \otimes R[e, e^{-1}] \]

and

\[ f_{\Gamma_{k+1}} = G \circ m_{k, \eta(v)} : B_k(\mathcal{H}[1]^{\bullet}) \otimes R[e, e^{-1}] \to \overline{\mathcal{C}}[1]^{\bullet} \otimes R[e, e^{-1}] \]

Since the degree of \(\Pi\), resp. \(G\), is 0, resp. \(-1\), \(m_{\Gamma_{k+1}}\), resp. \(f_{\Gamma_{k+1}}\), is of degree 1, resp. 0.

**Step 3.** General case.

Let \(v_1\) be the vertex closest to the root vertex \(v_0\). Cut the decorated planar tree at \(v_1\), then \(\Gamma\) is decomposed into decorated planar trees \(\Gamma^{(1)}, \ldots, \Gamma^{(\ell)}\) and an interval toward \(v_0\) in counter-clockwise order, see Figure 2.

Then we define

\[ m_{\Gamma} = \Pi \circ m_{\ell, \eta(v_1)} \circ (f_{\Gamma^{(1)}} \otimes \cdots \otimes f_{\Gamma^{(\ell)}}) \]
and
\[ f_\Gamma = G \circ m_{\ell, \eta(v_1)} \circ (f_{\Gamma(1)} \otimes \cdots \otimes f_{\Gamma(\ell)}). \]

Finally we define
\[ m'_k = \sum_{\Gamma \in G_{k+1}^+} T^E(\Gamma) m_{\Gamma} \]
and
\[ f_k = \sum_{\Gamma \in G_{k+1}^+} T^E(\Gamma) f_{\Gamma}. \]

As in §2.1, we obtain a graded coderivation
\[ \hat{d}' = \sum_k \hat{m}'_k : B(\mathcal{H}[1]^\bullet) \otimes \Lambda_{0, \text{nov}} \to B(\mathcal{H}[1]^\bullet) \otimes \Lambda_{0, \text{nov}} \]
and a (formal) coalgebra homomorphism
\[ \hat{f} : B(\mathcal{H}[1]^\bullet) \otimes \Lambda_{0, \text{nov}} \to B(C[1]^\bullet). \]

We will show the following:

**Proposition 3.4.**
\[ \hat{f} \circ \hat{d}' = \hat{d} \circ \hat{f}, \]
where \( \hat{d} = \sum_k \hat{m}_k : B(C[1]^\bullet) \to B(C[1]^\bullet) \).

Since \( f_1 = f_{\Gamma_0} \) is the inclusion, we find that \( \hat{f} \) is injective using the energy filtration and the number filtration on the bar complex. Then \( \hat{d}' \circ \hat{d} = 0 \) follows from \( \hat{d} \circ \hat{d} = 0 \). Hence we obtain the following:

**Corollary 3.5.** (1) \((\mathcal{H}[1]^\bullet \otimes \Lambda_{0, \text{nov}}, \{m'_k\})\) is a \(G\)-gapped filtered \(A_\infty\)-algebra.
(2) \(\hat{f}\) is a \(G\)-gapped \(A_\infty\)-homomorphism from \((\mathcal{H}[1]^\bullet \otimes \Lambda_{0, \text{nov}}, \{m'_k\})\) to \((C[1]^\bullet, \{m_k\})\).
The rest of this section is devoted to the proof of Proposition 3.4, which is equivalent to that
\[ f \circ d^2 = m \circ \hat{f} \]
as maps \( B(\mathcal{H}[1]^\bullet) \otimes \Lambda_{0,nov} \rightarrow C[1]^\bullet \), where
\[ f : B(\mathcal{H}[1]^\bullet) \otimes \Lambda_{0,nov} \rightarrow B(C[1]^\bullet) \oplus C[1]^\bullet, \]
and
\[ m : B(C[1]^\bullet) \rightarrow B(C[1]^\bullet) \oplus C[1]^\bullet. \]

Namely, \( f|_{B_k(\mathcal{H}[1]^\bullet) \otimes \Lambda_{0,nov}} = f_k, \) \( m|_{B_k(\mathcal{H}[1]^\bullet) \otimes \Lambda_{0,nov}} = m_k. \)

We introduce an order on \( \{(k,i)|k,i = 0,1,2,\ldots\} \) by \( (k_1,i_1) \prec (k_2,i_2) \) if either \( i_1 < i_2 \) or \( i_1 = i_2 \) and \( k_1 < k_2 \). We show the following claim by the induction on \( (k,i) \).

Claim \((k,i)\).

\[ f \circ d^2 \equiv m \circ \hat{f} \mod T^{(i+1)} \cdot C[1]^\bullet \text{ on } B_k(\mathcal{H}[1]^\bullet) \otimes \Lambda_{0,nov}. \]

The key ingredients in the proof are the following relations presented in Figures 3,4.

Firstly, we consider the case that \( i = 0 \). Claim \((0,0)\) follows from the gapped condition. By the choice of \( \mathcal{H} \), Claim \((1,0)\) holds clearly. Suppose that Claim \((\ell,0)\) holds for \( \ell < k \). Note that
\[ \tilde{f}_k = f_{k,0} = \left( \sum_{1<\ell \leq k} G \circ \tilde{m}_\ell \circ \hat{f} + \delta_{k_1} f_{G_0} \right)|_{B_k(\mathcal{H}[1]^\bullet)} \]
and
\[ \tilde{m}_k = m_{k,0} = \left( \sum_{1<\ell \leq k} \Pi \circ \tilde{m}_\ell \circ \hat{f} + \delta_{k_1} m_{G_0} \right)|_{B_k(\mathcal{H}[1]^\bullet)}. \]

Here \( \delta_{ij} \) is Kronecker’s delta. Recall that \( m_{G_0} = m_{1,0}|_\mathcal{H} \) and \( f_{G_0} \) is the inclusion. Note also that the restriction of \( \hat{f} \) to \( B_k(\mathcal{H}[1]^\bullet) \) in the right hand sides is determined by \( \tilde{f}_1, \ldots, \tilde{f}_{k-1} \).

Thus we have
\[
\tilde{m} \circ \hat{f}|_{B_k(\mathcal{H}[1]^\bullet)} = \left( \tilde{m}_1 \circ \hat{f} + \sum_{1<\ell \leq k} \tilde{m}_\ell \circ \hat{f} \right)|_{B_k(\mathcal{H}[1]^\bullet)}
\]
\[
= \left( \sum_{1<\ell \leq k} \tilde{m}_1 \circ G \circ \tilde{m}_\ell \circ \hat{f} + \delta_{k_1} \tilde{m}_1 \circ f_{G_0} \right)|_{B_k(\mathcal{H}[1]^\bullet)}
\]
\[
= \left( \sum_{1<\ell \leq k} \Pi \circ \tilde{m}_\ell \circ \hat{f} - \sum_{1<\ell \leq k} G \circ \tilde{m}_\ell \circ \hat{f} + \delta_{k_1} \tilde{m}_1 \circ f_{G_0} \right)|_{B_k(\mathcal{H}[1]^\bullet)}
\]
\[
= \left( f_{G_0} \circ \tilde{m}_k - \sum_{1<\ell \leq k} G \circ \tilde{m}_1 \circ \tilde{m}_\ell \circ \hat{f} \right)|_{B_k(\mathcal{H}[1]^\bullet)}
\]
\[
= \left( f_{G_0} \circ \tilde{m}_k + \sum_{1<\ell \leq k} G \circ \tilde{m}_\ell \circ \hat{d} \circ \hat{f} \right)|_{B_k(\mathcal{H}[1]^\bullet)}.\]
\[ G \Rightarrow \text{id.} \]

**Figure 3.**

\[ \sum_{\ell = \ell_1 + \ell_2} m_\ell - \delta_{\ell_1,1} \cdot \overline{m}_1 = 0 \]

filtered \( A_\infty \)-relations

**Figure 4.**

\[ m_\ell - \delta_{\ell_1,1} \cdot \overline{m}_1 = \]

inserting \( \text{id.} \)
Here we used the fact that $\overline{m}_1 \circ G + G \circ \overline{m}_1 = \Pi - id$ and the $A_\infty$-relation $\overline{d} \circ \overline{d} = 0$. Since we assumed Claim $(\ell, 0)$ for $\ell < k$, i.e.,

$$\overline{m} \circ \overline{f} = \overline{f} \circ \overline{d} \quad \text{on } B_k(\mathcal{H}[1]^\ast),$$

we have

$$\overline{d} \circ \overline{f} = \overline{f} \circ \overline{d} \quad \text{mod } \overline{C}[1]^\ast = B_1(\overline{C}[1]^\ast) \text{ on } B_k(\mathcal{H}[1]^\ast).$$

Therefore we find that

$$(\sum_{1 < \ell' \leq k} G \circ \overline{m}_{\ell'} \circ \overline{d} \circ \overline{f})|_{B_k(\mathcal{H}[1]^\ast)} = (\sum_{1 < \ell' \leq k} G \circ \overline{m}_{\ell'} \circ \overline{f} \circ \overline{d})|_{B_k(\mathcal{H}[1]^\ast)}.$$  

Hence we showed Claim $(k, 0)$, i.e.,

$$\overline{m} \circ \overline{f} = \overline{f} \circ \overline{d} \quad \text{on } B_k(\mathcal{H}[1]^\ast).$$

Next we assume that Claim $(k, i)$ holds for all $k = 0, 1, 2, \ldots$. We prove Claim $(k, i+1)$ by the induction on $k$. Note that Case 3-1 below does not occur in the case that $k = 0$.

First of all, we recall from the definition of $G_{k+1}^+$ that

$$t_k = \sum_{r \in G_{k+1}^+} T_{\lambda(r)} |_{r^k} = \sum_{(\ell,j) \neq (1,0)} G \circ \overline{m}_{\ell,j} \circ \overline{f} |_{B_k(\mathcal{H}[1]^\ast)} \otimes \Lambda_{0,\text{nov}} + \delta_{k1} f_{r_0}.$$  

Then we have

$$\overline{m} \circ \overline{f} |_{B_k(\mathcal{H}[1]^\ast)} = (\overline{m}_{1,0} \circ \overline{f} + \sum_{(\ell,j) \neq (1,0)} \overline{m}_{\ell,j} \circ \overline{f})|_{B_k(\mathcal{H}[1]^\ast)}$$

$$= (\sum_{(\ell,j) \neq (1,0)} \Pi \circ \overline{m}_{\ell,j} \circ \overline{f} - \sum_{(\ell,j) \neq (1,0)} G \circ \overline{m}_{1,0} \circ \overline{m}_{\ell,j} \circ \overline{f}$$

$$+ \delta_{k1} m_{1,0} \circ f_{r_0})|_{B_k(\mathcal{H}[1]^\ast)}$$

$$= (f_{r_0} \circ m_{k} - \sum_{(\ell,j) \neq (1,0)} G \circ \overline{m}_{1,0} \circ \overline{m}_{\ell,j} \circ \overline{f})|_{B_k(\mathcal{H}[1]^\ast)}$$

$$= (f_{r_0} \circ m_k + \sum_{(\ell',j') \neq (1,0)} G \circ \overline{m}_{\ell',j'} \circ \overline{d} \circ \overline{f})|_{B_k(\mathcal{H}[1]^\ast)}.$$  

In the third equality, we used the fact that $m_{1,0} \circ G + G \circ m_{1,0} = \Pi - id$.

We will show that

$$\sum_{(\ell',j') \neq (1,0)} G \circ \overline{m}_{\ell',j'} \circ \overline{d} \circ \overline{f} \equiv \sum_{(\ell',j') \neq (1,0)} G \circ \overline{m}_{\ell',j'} \circ \overline{f} \circ \overline{d} \quad \text{mod } T^{\Lambda_{k+2}},$$

which implies that

$$m \circ \overline{f} \equiv \overline{f} \circ \overline{d} \quad \text{mod } T^{\Lambda_{k+2}}.$$
Case 1: $\ell' = 0$. Note that the $B_0(C[1]^\bullet) = \Lambda_{0,nov}$-components of $\text{Im} \, \hat{d} \circ \hat{f}$ and $\text{Im} \, \hat{f} \circ \hat{d}'$ are zero. Hence we have
\[ m_{0,j'}^0 \circ \hat{d} \circ \hat{f} = m_{0,j'}^0 \circ \hat{f} \circ \hat{d}' = 0. \]

Case 2: $\ell' = 1$. For $j' \neq 0$, $m_{1,j'}^1 \equiv 0 \mod T^{\lambda(1)}$. By the induction hypothesis, we have
\[ \hat{f} \circ \hat{d}' \equiv \hat{d} \circ \hat{f} \mod T^{\lambda(i+1)}. \]
Since $\lambda_{(i+2)} \leq \lambda_{(i+1)} + \lambda_{(1)}$, we obtain
\[ m_{1,j'}^1 \circ \hat{f} \circ \hat{d}' \equiv m_{1,j'}^1 \circ \hat{d} \circ \hat{f} \mod T^{\lambda(i+2)}. \]

Case 3: $\ell' \geq 2$. Let $x \in B_k(\mathcal{H}[1]^\bullet) \otimes \Lambda_{0,nov}$. Write
\[ \Delta^\ell' \cdot x = \sum_a x_{1,a} \otimes \cdots \otimes x_{\ell',a}, \]
where $\Delta$ is the coproduct and $x_{j,a} \in B_{k_j,a}(\mathcal{H}[1]^\bullet) \otimes \Lambda_{0,nov}$. Then we have
\[ \hat{f} \circ \hat{d}'(x) = \sum_a \sum_j (-1)^{\deg x_{j,a}} x_{j,a} \otimes \cdots \otimes f_{k_j,a}(d'(x_{j,a})) \otimes \cdots \otimes f_{k_{\ell'},a}(x_{\ell',a}). \]

Case 3-1: $k_{j,a} < k$. In this case, we have
\[ f_{k_{j,a}}(d'(x_{j,a})) \equiv m \circ \hat{f}(x_{j,a}) \mod T^{\lambda(i+2)} \]
by the induction hypothesis. Hence
\[ f_{k_{1,a}}(x_{1,a}) \otimes \cdots \otimes f_{k.j,a}(d'(x_{j,a})) \otimes \cdots \otimes f_{k_{\ell'},a}(x_{\ell',a}) \equiv f_{k_{1,a}}(x_{1,a}) \otimes \cdots \otimes m \circ \hat{f}(x_{j,a}) \otimes \cdots \otimes f_{k_{\ell'},a}(x_{\ell',a}) \mod T^{\lambda(i+2)}. \]

Case 3-2: $k_{j,a} = k$. In this case, $k_{j',a} = 0$ for $j' \neq j$, i.e., $x_{j',a} \in B_0(\mathcal{H}[1]^\bullet) \otimes \Lambda_{0,nov}$. Without loss of generality, we may assume that $x_{j',a} = 1$ for $j' \neq j$.

By the induction hypothesis, we have
\[ f(d'(x_{j,a})) \equiv m(f(x_{j,a})) \mod T^{\lambda(i+1)}, \]
which implies that
\[ f_0(1) \otimes \cdots \otimes f(d'(x_{j,a})) \otimes \cdots \otimes f_1(1) \equiv f_0(1) \otimes \cdots \otimes m(f(x_{j,a})) \otimes \cdots \otimes f_1(1) \mod T^{\lambda(i+2)}. \]

Here we used $f_0(1) \equiv 0 \mod T^{\lambda(1)}$.

In sum, we obtain Claim $(k, i + 1)$ for all $k$.

By the construction, $\hat{T}_1$ is a chain homotopy equivalence ($\Pi$ is a homotopy inverse). Therefore, Theorem 2.2 implies that $\{f_k\}$ is a homotopy equivalence of filtered $A_{\infty}$-algebras.
4. Filtered $A_\infty$-algebra associated to Lagrangian submanifolds

Let $(M, \omega)$ be a closed symplectic manifold and $L$ a Lagrangian submanifold. We only consider the case that $L$ is an embedded compact Lagrangian submanifold without boundary equipped with a relative spin structure, see §44 in [6]. We constructed a filtered $A_\infty$-algebra associated to $L$ in $(M, \omega)$. As we explained in section 2, the framework of (filtered) $A_\infty$-algebras, bimodules, etc. is adequate to formulate the condition under which Floer complex is obtained.

In this section, we briefly recall the way of constructing filtered $A_\infty$-algebra associated to $L$. Although the readers may find Proposition 4.1 below too technical, we present it precisely so that we can explain how to modify it for the purpose of section 5.

A naive idea of the construction is to use the moduli space of pseudo-holomorphic discs to deform the intersection products of chains in $L$ in a similar way to the quantum cohomology, where the intersection product on (co)homology is deformed by the moduli space of pseudo-holomorphic spheres, more precisely, stable maps of genus 0. Here appears a difference: while the moduli spaces of stable maps of genus 0 are (virtual) cycles, the moduli spaces of stable bordered stable maps are, in general, not (virtual) cycles, but with codimension 1 boundary (in the sense of Kuranishi structure). Therefore, we cannot restrict ourselves to cycles and forced to work with chains. However, the intersection product is not defined in chain level, e.g., the self intersection of chains. We start with a subcomplex of the singular chain complex to work with chains. However, the intersection product is not defined in chain level, Kuranishi structure). Therefore, we cannot restrict ourselves to cycles and forced to work with chains. However, the intersection product is not defined in chain level, e.g., the self intersection of chains. We start with a subcomplex of the singular chain complex such that the inclusion induces an isomorphism on homology. Then take perturbed intersection product of generators of the subcomplex and add them to get a larger subcomplex such that the inclusion induces an isomorphism on homology. Once we get such nested subcomplexes, we apply the argument in the proof of Theorem 3.3 to define the operation $\overline{m}_2$ on a fixed subcomplex. This multiplicative structure is not associative, but associative up to homotopy. So we proceed to constructed other operations $\overline{m}_k$ in a similar way, see Corollary 30.89 in section 30.6, [6] for a detailed argument. In this way, we obtain an $A_\infty$-algebra.

For the construction of the filtered $A_\infty$-algebra, we include the effect from the moduli space of bordered stable maps. We need to take perturbations of the moduli spaces to define the operations not only perturbation in the intersection product mentioned above. Our strategy is to construct an $A_{n,K}$-algebra on $C'_g(L)$, which is generated by $\chi_{(g)}$ in Proposition 30.11 for a sufficiently large $g$. Then we use the obstruction theory to extend a filtered $A_{n,K}$-structure to a filtered $A_{n',K'}$-structure ($(n,K) \preceq (n',K')$). The resulting filtered $A_\infty$-structure is unique up to homotopy, see §30 in Chapter 7, [6].

Let $\mu_L \in H^2(M, L; \mathbb{Z})$ be the Maslov class of the Lagrangian submanifold $L$. We introduce an equivalence relation ~ on $H_2(M, L; \mathbb{Z})$ by $\beta_1 \sim \beta_2$ if and only if $\omega(\beta_1) = \omega(\beta_2)$ and $\mu_L(\beta_1) = \mu_L(\beta_2)$.

Pick an almost complex structure $J$ compatible with $\omega$. Denote by $\mathcal{M}(\beta; L, J)$ the moduli space of bordered stable maps $u : (\Sigma, \partial \Sigma) \to (M, L)$ of genus 0 representing $\beta$ and by $\mathcal{M}_{k+1}(\beta; L, J)$ be the moduli space of bordered stable maps in the class $\beta$ of genus 0 with $k + 1$ marked points $z_0, z_1, \ldots, z_k$ on the regular part of $\partial \Sigma$. Denote by $\mathcal{M}_{k+1}^\text{main}(\beta; L, J)$ the component, on which the marked points $z_0, z_1, \ldots, z_k$ respect the counter-clockwise cyclic order on the boundary of bordered semi-stable curve of genus 0 with connected boundary. Let $\mathfrak{S}(L)$ be the monoid contained in $\Pi(M, L)$ generated by $\beta$ with $\mathcal{M}(\beta; L, J) \neq \emptyset$. We write $\beta_0 = 0 \in \mathfrak{S}(L)$. 
Our basic idea is as follows. For singular simplices $P_1, \ldots, P_k$ in $L$, we consider the fiber product in the sense of Kuranishi structure

$$\mathcal{M}^\text{main}_{k+1}(\beta; P_1, \ldots, P_k) = \mathcal{M}^\text{main}_{k+1}(\beta; L, J)_{ev} \times_{L^k} (P_1 \times \cdots \times P_k),$$

where $ev = (ev_1, \ldots, ev_k)$ is the evaluation map at $z_1, \ldots, z_k$. (For the orientation issue, see Chapter 9 [8].) Then we would like to define

$$m_{k,\beta}(P_1, \ldots, P_k) = (ev_0 : \mathcal{M}^\text{main}_{k+1}(\beta; P_1, \ldots, P_k) \to L),$$

where $ev_0$ is the evaluation at $z_0$.

Note that $\mathcal{M}^\text{main}_{k+1}(\beta)$ is not necessarily a manifold or an orbifold and that $ev_i$ are not necessarily submersions even if $\mathcal{M}^\text{main}_{k+1}(\beta)$ is such a nice space. In order to deal with this issue, we introduced the notion of Kuranishi structure [8], see also Appendix in [6]. Here is a digression on Kuranishi structure.

Let $X$ be a compact Hausdorff space. A Kuranishi structure on $X$ consists of a covering of $X$ by Kuranishi neighborhoods of the same virtual dimension and coordinate changes among them. A Kuranishi neighborhood around $p \in X$ is a quintet $(V_p, E_p, \Gamma_p, s_p, \psi_p)$, where

- $V_p$ is a smooth manifold of finite dimension,
- $E_p$ is a real vector bundle over $V_p$ of finite rank,
- $\Gamma_p$ is a finite group acting smoothly and effectively on $V_p$ and $E_p$ such that $E_p \to V_p$ is a $\Gamma_p$-equivariant vector bundle,
- $s_p$ is a $\Gamma_p$-equivariant section of $E_p \to V_p$,
- $\psi_p$ is a homeomorphism from $s_p^{-1}(0)/\Gamma_p$ to a neighborhood of $p$ in $X$.

The vector bundle $E_p \to V_p$ is called the obstruction bundle and the section $s_p$ the Kuranishi map. We have coordinate changes among Kuranishi neighborhoods, see [8, 6]. We require that $\dim V_p - \text{rank } E_p$ does not depend on $p \in X$ and call it the virtual dimension of the space $X$ equipped with Kuranishi structure.

The moduli spaces of stable maps, bordered stable maps carry Kuranishi structures, hence we can locally describe the moduli space as $s_p^{-1}(0)/\Gamma_p$ in the definition of Kuranishi neighborhoods. If $s_p$ is transversal to the zero section, the moduli space is locally an orbifold. In general, we cannot perturb $s_p$ to a $\Gamma_p$-equivariant section $s'_p$, which is transversal to the zero section. Instead of single valued sections, we consider perturbations by $\Gamma_p$-equivariant multi-valued sections, each branch of which is transversal to the zero section. Then we arrange them compatible under the coordinate change. In this way, we obtain perturbed moduli spaces.

We take a multi-valued perturbation $s$ of Kuranishi maps for $\mathcal{M}^\text{main}_{k+1}(\beta; P_1, \ldots, P_k)$ such that each branch of $s$ is transversal to the zero section. After taking a triangulation of the perturbed zero locus $\mathcal{M}^\text{main}_{k+1}(\beta; P_1, \ldots, P_k)_s$ of $s$, we obtain a virtual chain

$$ev_0 : \mathcal{M}^\text{main}_{k+1}(\beta; P_1, \ldots, P_k)_s \to L.$$

To make this argument rigorous, we build a sequence of subcomplexes of the singular chain complex of $L$ and a series of operations $m_{k,\beta}^\text{pert}$. For details, see Chapter 7 in [6]. Here we briefly recall a part of it, in particular, the construction of a series of subcomplexes of singular chain complex of $L$. In section 5, we explain how to arrange this construction in relation with the Morse theory.
In §30 in [6], we constructed countable sets \( \chi_g(L) \) of singular \( C^\infty \)-simplices on \( L \). For a simplex \( P \in \chi_g(L) \), we call \( g \) the generation of \( P \). Write
\[
\chi(g) = \bigcup_{g' \leq g} \chi_{g'}(L)
\]
and denote by \( C_g(L; R) \) the \( R \)-vector space generated by \( \chi(g)(L) \). Let \( S(L; R) \) be the singular \( C^\infty \)-chain complex of \( L \) with coefficients in \( R \).

**Condition 1.** Any face of \( P \in \chi_g(L) \) belongs to \( \chi_{g'}(L) \).

**Condition 2.** The inclusion \( C_g(L) \to S(L; R) \) induces an isomorphism on homology.

For \( \beta \in \mathfrak{G}(L) \), we define
\[
\| \beta \| = \begin{cases} 
\sup\{n|\exists \beta_1, \ldots, \beta_n \in \mathfrak{G}(L) \setminus \{\beta_0\}, \sum_{i=1}^n \beta_i = \beta\} + |\omega(\beta)| - 1 & \text{if } \beta \neq \beta_0 \\
-1 & \text{if } \beta = \beta_0
\end{cases}
\]

Here \( |\omega(\beta)| \) is the largest integer not greater than \( \omega(\beta) \).

By Gromov’s compactness, the number of \( \beta \in \mathfrak{G}(L) \) with \( \| \beta \| \leq C \) is finite for any \( C \).

Next we introduce an additional data \( \mathfrak{d} : \{1, \ldots, k\} \to \mathbb{Z}_{\geq 0} \), which is called a decoration. For a pair \( (\mathfrak{d}, \beta) \) such that \( \mathcal{M}^\text{main}_{k+1}(\beta) \neq \emptyset \), we define
\[
\| (\mathfrak{d}, \beta) \| = \begin{cases} 
\max_{i \in \{1, \ldots, k\}} \mathfrak{d}(i) + \| \beta \| + k & \text{if } k \neq 0 \\
\| \beta \| & \text{if } k = 0.
\end{cases}
\]

We will take the fiber product of \( \mathcal{M}^\text{main}_{k+1}(\beta) \) and singular simplices \( P_i \) in \( L \). The decoration \( \mathfrak{d} \) is introduced in order to include the generations of singular simplices \( P_i \) into the data. When we emphasize that the decoration \( \mathfrak{d} \) is equipped with the moduli space \( \mathcal{M}^\text{main}_{k+1}(\beta) \), we denote it by \( \mathcal{M}^\text{main,\mathfrak{d}}_{k+1}(\beta) \).

**Proposition 4.1** (Proposition 30.35 in [6]). For any \( \delta > 0 \) and \( K > 0 \), there exist \( \chi_g(L) \), \( g = 0, \ldots, K \), and multisections \( s_{\mathfrak{d}, k, \beta, \vec{P}} \) for \( \| (\mathfrak{d}, \beta) \| \leq K \) with the following properties:

- \( \chi_g(L) \) satisfies Conditions 1 and 2 above.
- Let \( P_i \in \chi_{\mathfrak{d}(i)}(L), i = 1, \ldots, k \). We put
  \[
  \mathcal{M}^\text{main,\mathfrak{d}}_{k+1}(\beta; P_1, \ldots, P_k) = \mathcal{M}^\text{main,\mathfrak{d}}_{k+1}(\beta) \times_{L^k} \prod_{i=1}^k P_i
  \]
  and define a multisection \( s_{\mathfrak{d}, k, \beta, \vec{P}} \) thereof. \( s_{\mathfrak{d}, k, \beta, \vec{P}} \) is transversal to the zero section.
- If \( g = \| (\mathfrak{d}, \beta) \| \), then
  \[
  ev_{\mathfrak{d}, \beta}(\mathcal{M}^\text{main,\mathfrak{d}}_{k+1}(\beta; P_1, \ldots, P_k) \times_{L^k} \prod_{i=1}^k P_i)
  \]
  is decomposed into elements of \( \chi_g(L) \). Here and henceforth we denote
  \[
  \mathcal{M}^\text{main,\mathfrak{d}}_{k+1}(\beta; P_1, \ldots, P_k) \times_{L^k} \prod_{i=1}^k P_i s_{\mathfrak{d}, k, \beta, \vec{P}}^{-1} := s_{\mathfrak{d}, k, \beta, \vec{P}}^{-1}(0).
  \]
- The multisections \( s_{\mathfrak{d}, k, \beta, \vec{P}} \) satisfy certain compatibility conditions.
- The zero locus \( s_{\mathfrak{d}, k, \beta, \vec{P}}^{-1}(0) \) is in a \( \delta \)-neighborhood of the zero locus of the original Kuranishi map.
For the compatibility conditions in the above statement, see Conditions 30.38 and 30.44 in [6].

Now we explain the way of constructing the filtered $A_\infty$-algebra associated to $L$. We put
\[ m_{k,\beta}^{geo}(P_1, \ldots, P_k) = (ev_0 : M_{k+1}^{main, \delta}(\beta; P_1, \ldots, P_k) \otimes \Lambda_0, nov \rightarrow L), \]
when $P_i \in \chi_{(g)}$, $i = 1, \ldots, k$. Then $m_{k,\beta}^{geo}(P_1, \ldots, P_k)$ is decomposed into elements of $\chi_{(g)}$, where $g = \| (0, \beta) \|$. Using the idea in section 3, we showed the following:

**Proposition 4.2** (Proposition 30.78 in [6]). For any $g_0$, $n$, $K$, there exists $g_1 > g_0$ and a filtered $A_{n,K}$-structure $m_{k,\beta}$ on $C(L) \otimes \Lambda_0, nov$ such that
\[ m_{k,\beta}(P_1, \ldots, P_k) = m_{k,\beta}^{geo}(P_1, \ldots, P_k), \]
if $P_i \in \chi_{(g_0)}(L)$.

Combining Theorem 2.4 and Proposition 4.2, we can construct a filtered $A_\infty$-algebra associated to $L$, for details see [6]. Hence we obtain

**Theorem 4.3** (Theorem 10.11 in [6]). Let $L$ be a relatively spin Lagrangian submanifold. Then there exist a countably generated subcomplex $C(L)$ of the singular chain complex and a filtered $A_\infty$-algebra structure on $C(L) \otimes \Lambda_0, nov$.

We also proved that the homotopy type of the filtered $A_\infty$-algebra is unique.

Applying the construction of canonical models in section 3, we obtain a filtered $A_\infty$-algebra associated to $L$, for details see [6].

5. Canonical models and Morse complexes

In this section, we apply Theorem 4.3 and reduce the filtered $A_\infty$-structure on $C^*(L) \otimes \Lambda_0, nov$ to the Morse complex $CM^*(f) \otimes \Lambda_0, nov$.

We pick a specific Morse function as follows. Choose and fix a triangulation $\mathcal{T}$ of $L$. We may assume that the triangulation is sufficiently fine by taking subdivision. Pick a Morse function $f : L \rightarrow \mathbb{R}$ with the following property. Critical points of $f$ are in one-to-one correspondence with barycenters of simplices. Moreover, the Morse index of a critical point is equal to the dimension of the corresponding simplex. Then we can take a gradient-like vector field $X$ such that the unstable manifold $W^u(p)$ at each critical point $p$ is the interior of the corresponding simplex. Denote by $\{\rho_i\}$ the flow generated by $X$. (The function $f$ increases along the orbits of $\{\rho_i\}$.)

Now we prove the following:

**Theorem 5.1.** Let $L$ be a relatively spin Lagrangian submanifold in a closed symplectic manifold $(M, \omega)$ and $f$ a Morse function on $L$ as above. Then Morse complex $CM^*(f) \otimes \Lambda_0, nov$ carries a structure of a filtered $A_\infty$-algebra, which is homotopy equivalent to the filtered $A_\infty$-algebra associated to $L$ constructed in [6].
The proof occupies the rest of this section. We explain how to choose $\chi_g(L)$ in section 4. Firstly, we choose and fix a linear order on the set of vertices in $\mathcal{T}$. Then we regard each $T_i \in \mathcal{T}$ as a singular simplex by the affine parametrization $\sigma_i : \Delta_k \to T_i$ respecting the order of the vertices. In particular, all simplices are oriented, hence the unstable manifolds $W^u(p)$. For our construction, we have to start with the following set of singular simplices. Set $\chi_{\mathcal{T}}(L) = \{ \sigma_i \}$ and identify the Morse complex $CM^\bullet(f)$ with $C_{\mathcal{T}}(L)$, which is a subcomplex of the singular chain complex of $L$ generated by $\chi_{\mathcal{T}}(L)$. Note that $\chi_{\mathcal{T}}(L)$ satisfies Conditions 1 and 2 given in section 4.

We define $\chi_g(L) \supset \chi_{\mathcal{T}}(L)$ in an inductive way as follows. For $g = -1$, we set $\chi_{-1}(L) = \chi_{\mathcal{T}}(L)$. For $g = 0, 1, \ldots$, suppose that we constructed $\chi_{g'}(L)$, $g' < g$.

We can choose the perturbations $\mathcal{S}_{g,k,\beta,\bar{P}}$ in Proposition 5.1 with the following property.

Each face $\tau$ of any simplex in the triangulation of $ev_{0*} \left( M_{k+1}^{\text{main}, \partial} (\beta; P_1, \ldots, P_k \} \right)^{g,k,\beta,\bar{P}}$

with $g = \| (\alpha, \beta) \|$ is transversal to the stable manifold $W^s(p)$ at any $p \in \text{Crit}(f)$. Moreover, for each $\tau$ of dimension at most $\dim L$, there exists at most one $p = p(\tau) \in \text{Crit}(f)$ such that the stable submanifold $W^s(p)$ is of complementary dimension to $\tau$ and $W^s(p)$ and $\tau$ intersect at a unique point. Denote by $T(p) \in \mathcal{T}$ the simplex containing $p$. Let $\chi^0_g(L)$ be the set of these singular simplices $\tau$.

We have to add $\chi^0_g(L)$ to previous $\bigcup_{g' < g} \chi_{g'}(L)$. In order to guarantee Condition 2, we further add the following singular simplices to $\chi^0_g(L)$ and obtain $\chi_g(L)$. Denote by $\sigma^\tau \in \chi_{\mathcal{T}}$ the singular simplex corresponding to $T(p(\tau))$. Define $\Pi(\tau) = \epsilon \sigma^\tau$, where $\epsilon = \pm 1$ is given by the following equation.

$$\tau \cap W^s(p(\tau)) = \epsilon W^u(p(\tau)) \cap W^s(p(\tau)), $$

if there exists a unique stable manifold $W^s(p(\tau))$, which intersects $\tau$ transversely at a unique point. Otherwise, we define $\Pi(\tau) = 0$. In particular, if $\tau \supset \dim L$, $\Pi(\tau) = 0$. For each $\tau$ as above, we will find a singular chain $G(\tau)$ such that

$$\Pi(\tau) - \tau = \overline{\partial} G(\tau) + G(\overline{\partial} \tau),$$

where $\overline{\partial} = (-1)^{\dim L} \partial$. We can find such $G(\tau)$ by induction on dimension of $\tau$. In our case, we construct $G(\tau)$ using the gradient-like flow $\{ \rho_t \}$. Set

$$\tau(\text{Im} \tau) = \bigcup_{t \leq 0} \rho_t(\text{Im} \tau).$$

By the choice of our perturbations above, the closure of $\tau(\text{Im} \tau)$ can be triangulated in a compatible way with $\tau$ and $\Pi(\tau)$. Pick such a triangulation and then define $G(\tau)$ the corresponding singular chain. For the chain $G(\tau)$, we define $G(G(\tau)) = 0$.

Note that $\Pi : C(g)(L) \to C(g)(L)$ and $G : C(g)(L) \to C(g)(L)$ satisfy the conditions in Lemma 3.2, hence $C(g)(L)$ satisfies Condition 2. Therefore we can apply Theorem 3.3 to reduce the filtered $\Lambda_\infty$-structure on $CM^\bullet(f) \otimes \Lambda_{0, \text{nov}}$ and obtain a filtered $\Lambda_\infty$-algebra $(CM^\bullet(f) \otimes \Lambda_{0, \text{nov}}, \{ m^\infty_k \})$, which is homotopy equivalent to $(C(g)(L) \otimes \Lambda_{0, \text{nov}}, \{ m_k \})$. Theorem 3.3 is proved.

In the proof of Theorem 3.3, we constructed the operator $m^\infty_k$ from $m_\Gamma$, $\Gamma \in G^+_L$. The geometric meaning of $m_\Gamma$ is as follows. Recall that $G(\tau)$ assigns the closure of the union of flow lines arriving at $\tau$. We assign $G$ to the interior edges. The interior vertices correspond to $J$-holomorphic discs, more precisely, bordered stable maps
of genus 0. In order to describe the operation $m_\Gamma$, we need only rigid configuration of $\tau_i \in \chi_T(L)$ (the barycenters of $\tau_i$ are inputs), $J$-holomorphic discs, (broken) negative flow lines of $X$ and $W^s(q)$ ($q$ is the output). We choose the perturbation $s$ generically so that the moduli spaces of holomorphic discs and the flow $\{\rho_t\}$ are in general position so that the inner edges correspond to negative flow lines of $X$. Hence the $m_\Gamma$ is defined by using the configuration of pseudo-holomorphic discs and Morse negative gradient trajectories according to the decorated tree $\Gamma \in \cup_k G_k^{\Gamma+1}$.

For a decorated tree $\Gamma \in G_k^{\Gamma+1}$, each edge is oriented in the direction from the $k$ input vertices to the root vertex. We denote by $v^\pm(e)$ the vertices such that $e$ is an oriented edge from $v^-(e)$ to $v^+(e)$. Consider the moduli space $\mathcal{M}_\Gamma(h; p_1, \ldots, p_k, q)$ consisting of the configuration of the following

- for each interior vertex $v \in \Gamma$, a bordered stable map $u_v$ representing the class $\beta_{n(v)}$ with $\ell(v)$ boundary marked points, where $\ell(v)$ is the valency of $v$, (we denote by $p(e, v)$ the marked point corresponding to the edge $e$ attached to $v$)
- the $i$-th input edge $e_i$ corresponds to a broken negative gradient flow line $\gamma_i$ starting from the critical point $p_i$ to $u_{v^+(e_i)}(p(e_i, v^+(e_i)))$,
- the output edge corresponds to a broken negative gradient flow line $\gamma_0$ from $u_{v^-(e_0)}(p(e_0, v^-(e_0)))$ ending at the critical point $q$,
- an interior edge $e$ corresponds to a broken negative gradient flow line $\gamma_e$ from $u_{v^-(e)}(p(e, v^-(e)))$ to $u_{v^+(e)}(p(e, v^+(e)))$.

Counting the weighted order of the moduli spaces of virtual dimension 0, we get

$$m_\Gamma(p_1 \times \cdots \times p_k) = \sum_{q} \# \mathcal{M}_\Gamma(h; p_1, \ldots, p_k, q) \cdot e^{\sum_i \mu(\beta_{n(v)})/2}$$

and

$$m_k = \sum_{\Gamma \in G_k^{\Gamma+1}} T_{E(T)} E_{\Gamma} m_\Gamma.$$ 

For example, we obtain the configuration as in Figure 4 associated to the decorated planar tree $\Gamma$ with inputs $T(p), T(p'), T(p'') \in \chi_T(L)$ as in Figure 4.

This is essentially the configuration introduced in [4]. Note that the first named author [3] took multiple Morse functions to achieve transversality. Here we use one Morse function and apply the argument in section 3 to squeeze the filtered $A_\infty$-algebra structure to the Morse complex. We emphasize that this becomes possible only after working out the chain level intersection theory in detail, which we explained in section 4. To find an appropriate perturbation of $\mathcal{M}_\Gamma(h; p_1, \ldots, p_k, q)$ directly without using the argument in section 4 (or section 30 in [5]) seems extremely difficult.

The use of multiple Morse functions enables to construct the topological (or partial) filtered $A_\infty$-category of Morse functions on $L$ in the case that $m_0 = 0$. Note that, in a topological (or partial) filtered $A_\infty$-category $\mathcal{A}$, the set $\text{Ob}_\mathcal{A}$ of objects is a topological space and the set $\text{Mor}_\mathcal{A}(a, b)$ of morphisms is defined for $(a, b)$ in an open dense subset of $\text{Ob}_\mathcal{A} \times \text{Ob}_\mathcal{A}$. When $\mathcal{A}$ is a filtered $A_\infty$-category, each object $a$ is equipped with the filtered $A_\infty$-algebra $\text{Mor}_\mathcal{A}(a, a)$. In our case, the filtered $A_\infty$-algebra on Morse complex $CM^\bullet(f)$ corresponds to the filtered $A_\infty$-algebra associated to the object $f$. Note that, in the construction of this paper and in Theorem 5.1, we do not need to assume that $m_0 = 0$ in our construction.
For a relative spin pair \((L_0, L_1)\) of Lagrangian submanifolds, which intersect transversely, we obtain the filtered \(A_\infty\)-bimodule over the filtered \(A_\infty\)-algebras on \(CM^\bullet(f_i) \otimes \Lambda_{0,nov}\), where \(f_i : L_i \to \mathbb{R}, i = 0, 1,\) are Morse functions. When \(L_0\) and \(L_1\) are of clean intersection, there exists a certain local system \(\Theta\) on \(L_0 \cap L_1\) and we can reduce the filtered \(A_\infty\)-bimodule structure on \(C^\bullet(L_0 \cap L_1; \Theta) \otimes \Lambda_{0,nov}\) to \(CM^\bullet(h; \Theta) \otimes \Lambda_{0,nov}\) over the filtered \(A_\infty\)-algebras on \(CM^\bullet(f_i) \otimes \Lambda_{0,nov}\). Here \(h\) is a Morse function on \(L_0 \cap L_1\), which may be disconnected with various dimensions. For the canonical models of filtered \(A_\infty\)-bimodules, see [6].
