Abstract: This paper presents a new step in the optimization of the Chambadal model of the Carnot engine. It allows a sequential optimization of a model with internal irreversibilities. The optimization is performed successively with respect to various objectives (e.g., energy, efficiency, or power when introducing the duration of the cycle). New complementary results are reported, generalizing those recently published in the literature. In addition, the new concept of entropy production action is proposed. This concept induces new optimums concerning energy and power in the presence of internal irreversibilities inversely proportional to the cycle or transformation durations. This promising approach is related to applications but also to fundamental aspects.

Keywords: optimization; Carnot engine; Chambadal model; entropy production action; efficiency at maximum power

1. Introduction

Sadi Carnot had a crucial contribution to thermostatics that designated him as a co-founding researcher of equilibrium thermodynamics. He has shown that the efficiency of a thermo-mechanical engine is bounded by the Carnot efficiency $\eta_C$ [1]. Assuming an isothermal source at $T_{HS}$, and an isothermal sink at $T_{CS} < T_{HS}$, and in between the cycle composed by two isothermals in perfect thermal contact with the source and sink, and two isentropics, he obtained:

$$\eta_C = 1 - \frac{T_{CS}}{T_{HS}}.$$  (1)

Since that time, many papers have used the keyword “Carnot engine” (1290 papers from Web of Science on 17 September 2021). That same day on Web of Science, we noted 104 papers related to the keyword “Carnot efficiency”.

Among these papers, some are related to the connection between energy, efficiency, and power optimization. The most cited paper is probably that of Curzon and Ahlborn [2,3]. These authors proposed in 1975 an expression of the efficiency according to the first law of thermodynamics $\eta_1(MaxW)$ at the maximum mechanical energy and at the maximum power $W$ for the endo-reversible configuration of the Carnot cycle (no internal irreversibility for the converter in contact with two isothermal heat reservoirs):

$$\eta_{1,endo}(MaxW) = 1 - \sqrt{\frac{T_{CS}}{T_{HS}}}.$$  (2)

This result is well-known as the nice radical, and it has been recently reconsidered in the previous Special Issue Carnot Cycle and Heat Engine Fundamentals and Applications.
I [3] and particularly in [4]. This last paper reports on the progress in Carnot and Cham-
badal modeling of thermomechanical engines by considering entropy production and heat
transfer entropy in the adiabatic case (without heat losses).

The proposed paper gives back the basis of the modeling and a summary of the
main results obtained recently for an endo-irreversible Carnot engine. Furthermore, the
performance analysis of an extended Chambadal configuration is considered by including
the converter irreversibilities. Emphasis is placed on the entropy production method, which
is preferred over the ratio method.

2. Summary of Obtained Results for Carnot Endo-Irreversible Configuration

The consideration of endo-irreversible Carnot engine modeling was recently devel-
oped [5]. The approach considering as a reference the heat transfer entropy released at the
sink $\Delta S$ (maximum entropy available at the source in the reversible case) [5] confirmed
that the work per cycle results (see Appendix A):

$$W = (T_{HS} - T_{CS})(\Delta S_S - \Delta S_I),$$

where $\Delta S_I$ is the entropy production due to the internal irreversibilities of the cycle through-
out the four thermodynamic transformations (two adiabatic and two isothermal ones).

For an engine without thermal losses, the following expression of the thermal efficiency
was retrieved:

$$\eta_I = \eta_C(1 - d_I),$$

where $d_I = \frac{\Delta S_I}{\Delta S_S}$ is a coefficient of the converter’s internal irreversibility during the cycle.

This parameter was introduced by Novikov [6] and Ibrahim et al. [7] in slightly
different forms.

The reversible limit ($d_I = 0$) in Equation (4) restores the Carnot cycle efficiency associ-
ated with equilibrium thermodynamics.

Since the reversibility is unattainable, it appears that the optimization (maximization)
of the mechanical energy at the given parameters ($\Delta S_S, T_{HS}$, and $T_{CS}$) is related to the
minimization of the entropy production (as was proposed by Gouy [8]).

The assumption that each of the four transformations of the endo-irreversible cycle
takes place with a duration $\tau_i$ ($i = 1–4$), leading to the inverse proportionality to $\tau_i$ of the
corresponding entropy production:

$$\Delta S_{II} = \frac{C_{II}}{\tau_i},$$

where $C_{II}$ represents the irreversibility coefficients, whose unit is Js/K [5].

These coefficients are irreversible entropic actions by analogy to the energy (mechanical)
action (Js).

By performing cycle energy optimization using the Lagrange multipliers method with
the constraint of the cycle’s finite time duration $\tau$, one obtains the maximum work per
cycle [5]:

$$\text{Max}_1 W = W_{endo} - \frac{\Delta T_S}{\tau} \left( \sum_i \sqrt{C_{II}} \right)^2,$$

where $\Delta T_S = T_{HS} - T_{CS}$.

The efficiency at the maximum finite time work becomes

$$\eta_I(\text{Max}_1 W) = \eta_C \left( 1 - \frac{\left( \sum_i \sqrt{C_{II}} \right)^2}{\tau \Delta S_S} \right),$$

where $\tau \Delta S_S$ is the available entropic transfer action of the cycle.

The new result provided by Equation (7) gives back the Carnot efficiency limit for
the reversible case ($C_{II} = 0$). These calculations have been pursued for the case of power
optimization, where $\Delta S_S$, $T_{HS}$, and $T_{CS}$ remain parameters. It was shown that a value of the cycle duration $\tau^*$ corresponding to $\text{Max} W$, the mean power output over the cycle, exists, and it is expressed as

$$\tau^* = 8 \frac{C_{li}}{\Delta S'_S},$$

and

$$\text{Max} W = \frac{\Delta T_S \cdot \Delta S_S^2}{16 C_{li}}.$$  

Equation (9) proves that $\text{Max} W$ is a decreasing function of the total entropic action of the cycle and that the associated efficiency with the maximum of the mean power corresponds to half the Carnot efficiency, as appeared repeatedly in some recent works [9–11].

3. Summary of the Obtained Results for the Chambadal Configuration

In the present paper, we intend to reconsider the approach of the Chambadal model of a Carnot engine [12]. This configuration is common for thermomechanical engines, since the cold sink mainly refers to the environment (i.e., the atmosphere or water sink). This corresponds to the Chambadal approach (Figure 1), with a temperature gradient at the hot source ($T_{HS}$, $T_H$) but with perfect thermal contact at the sink ($T_{CS}$ or $T_0$ at ambient temperature).

We propose here to extend the results (Equations (6)–(9)) to enhance the Chambadal configuration modeling. This extension starts from the endo-irreversible case, to which external irreversibilities due to heat transfer between the hot finite source and the converter are added. Thus, the new results obtained complete the endo-irreversible Carnot model [5] and an earlier paper on Chambadal configuration [12].

3.1. The Modified Chambadal Engine

To help understand the extension of the modeling in Section 3, we report here the case with the following hypothesis:
1. Adiabaticity (no thermal losses);
2. Linear heat transfer law at the source such that

$$Q_H = G_H (T_{HS} - T_H),$$

where $G_H$ is the heat transfer conductance expressed by $G_H = K_H \tau$ when we consider the mean value over the cycle duration $\tau$ or $G_H = K_H' \tau_H$ when we consider the mean...
value over the isothermal heat transfer at the hot source (as was performed by Curzon and Ahlborn [2]).

Equation (10) corresponds to the heat expense of the engine.

Note that other heat transfer laws, namely the Stefan–Boltzmann radiation law, the Dulong–Petit law, and another phenomenological heat transfer law can be considered in the maximum power regime search [13];

3. Presence of irreversibility in the converter (internal irreversibility).

Two approaches are proposed in the literature, which introduce the internal irreversibility of the engine by (1) the irreversibility ratio \( I_H \), [6,7], respectively (2) the entropy production over the cycle \( \Delta S_I \), [5].

We preconized this second approach for a long time. We also note that the original model of Chambadal is endo-reversible [14]. Hence, we prefer to name the present model the “modified Chambadal model” due to some other differences that will be specified hereafter.

Note that only the second approach regarding the presence of irreversibilities in the converter will be considered in the following section.

3.2. Optimization of the Work per Cycle of the Modified Chambadal Engine with the Entropy Production Method

The first law of thermodynamics applied to the cycle implies conservation of energy, written as

\[
W = Q_{\text{conv}} - Q_S
\]  
(11)

where \( Q_{\text{conv}} \) and \( Q_S \) are defined in Appendix A.

One supposes here that \( \Delta S_I \) is a parameter representing the total production of entropy over the cycle composed by four irreversible transformations. Thus, the entropy balance corresponds to

\[
\frac{Q_{\text{conv}}}{T_H} + \Delta S_I = \frac{Q_S}{T_0}.
\]  
(12)

By combining Equations (11) and (12), we easily obtained

\[
W = Q_{\text{conv}} \left(1 - \frac{T_0}{T_H}\right) - T_0 \Delta S_I.
\]  
(13)

If \( Q_{\text{conv}} (\Delta S_{\text{conv}}) \) is a given parameter, we retrieve the Gouy-Stodola theorem stating that \( \text{Max } W \) corresponds to \( \min \Delta S_I \) with the known consequences reported in Section 4.1.

3.3. Optimization of the Work per Cycle of the Modified Chambadal Engine with the Heat Transfer Constraint

In this case, the energy balance between the source and isothermal transformation implies the combination of Equations (13) and (A1):

\[
W = (Q_H - T_H \Delta S_{I\text{H}}) \left(1 - \frac{T_0}{T_H}\right) - T_0 \Delta S_I.
\]  
(14)

Knowing \( Q_H \) from Equation (10), one obtains

\[
W = G_H (T_{HS} - T_H) \left(1 - \frac{T_0}{T_H}\right) - T_H \Delta S_{I\text{H}} - T_0 \Delta S_{I}'
\]  
(15)

where \( \Delta S_{I}' = \Delta S_{I\text{Ex}} + \Delta S_{I\text{C}} + \Delta S_{I\text{Co}} \).

The maximum of \( W \) with respect to \( T_H \) is obtained for

\[
T_H^* = \sqrt{\frac{T_{HS} T_0}{1 + s_I}}
\]  
(16)
where \( s_I = \frac{\Delta S_{IH}}{T_H} \), a specific ratio relative to the irreversible isothermal transformation \( T_H \).

Finally, the expression of \( \text{Max}_1 W \) yields

\[
\text{Max}_1 W = G_H \left( \sqrt{T_{HS}} - \sqrt{(1 + s_I)T_0} \right)^2 - T_0 \Delta S_I.
\]

(17)

4. Complement to the Previous Results

Now, we will consider the time variable related to entropy production for each thermodynamic transformation, defined as \( \Delta S_{Ii} = C_{Ii} \tau_i \). This form of the entropy production satisfying the second law induces that the entropy production method is well adapted to subsequent optimizations of energy and power as well.

4.1. Work Optimization Relative to the Time Variables

The expression of \( \text{Max}_1 W \) with \( G_H \) as an extensive parameter (Equation (17)) shows that \( \text{Max}_1 W \) is always the optimum in the endo-reversible case. Nevertheless, if there are separate irreversibilities for each cycle transformation (as is the case with finite entropic actions), the irreversibility on the high temperature isotherm possesses a specific role (see Equation (17) and the \( s_I \) ratio).

The constraint on the transformation duration or preferably frequencies \( f_i \) (finite cycle duration) allows one to seek for the optimal transformation duration allocation (see Appendix B for the derivation).

We obtained \( \text{Max}_2 W \) for the following optimal durations:

\[
\tau_{H}^* = \sqrt{\frac{T_0 C_{IH}}{\lambda}},
\]

(18)

and

\[
\tau_{i}^* = \sqrt{\frac{T_0 C_{Ii}}{\lambda}},
\]

(19)

where \( \lambda \) is given in Appendix B and \( i = \text{Ex}, \text{C}, \text{Co} \).

Thus, the second optimization of \( W \) (see Appendix B) leads to

\[
\text{Max}_2 W \approx W_{\text{endo}} - \frac{T_0 N^2}{\tau}. \]

(20)

Furthermore, a third sequential optimization could be performed by considering the finite entropic action as a new constraint. This case is not developed here for brevity reasons.

4.2. Power Optimization in the Case of a Finite Heat Source (When \( G_H \) Is the Parameter)

The mean power of the modified Chambadal cycle for the condition of maximum work \( \text{Max}_2 W \) is defined by

\[
\overline{W}(\text{Max}_2 W) = \frac{W_{\text{endo}}}{\tau} \frac{T_0}{\tau^2} N^2,
\]

(21)

where \( W_{\text{endo}} = G_H \left( \sqrt{T_{HS}} - \sqrt{T_0} \right)^2 \) is the mechanical work output of the endo-reversible engine.

The power is maximized with respect to the cycle period \( \tau \). Thus, the expression of the optimum period is

\[
\tau^* = \frac{2T_0 N^2}{W_{\text{endo}}}. \]

(22)

This expression is analogous to the similar results obtained in [5], leading to

\[
\text{Max} W = \frac{W_{\text{endo}}^2}{4T_0 N^2}.
\]

(23)
The action of entropy production appearing in $N$ diminishes the mean power of the engine. At the given endo-reversible work, the maximum power corresponds to the minimum of the $N$ function, depending on the four entropy actions of the cycle, such that

$$N = \sqrt{\frac{T_0}{T_{HS}}} C_{IH} + \sqrt{C_{IEx}} + \sqrt{C_{IC}} + \sqrt{C_{ICO}}.$$ (24)

The main difference between Equation (23) and the previous results [5] comes from the imperfect heat transfer between the source and the converter in the Chambadal model.

5. Discussion

This paper proposed that the Special Issue Carnot Cycle and Heat Engine Fundamentals and Applications II completes the previous paper [12] published in Special Issue 1 and adds new results to a recently published paper [5].

Whatever variable is chosen for the modified Chambadal model work optimization ($T_H$ or $\Delta S$), the same optimum for the work per cycle is obtained with parameters $G_H$, $T_{HS}$, and $T_0$.

It appears that by introducing the duration of each transformation $\tau_i$ and the period of the cycle $\tau$, the modified Chambadal model satisfies the Gouy-Stodola theorem. At the minimum of entropy production, the optimal durations are dependent on the transformation entropy actions. This result is new to our knowledge.

This new concept [5] allows a new subsequent sequential optimization. The optimal allocation of the entropy action coefficients is slightly different from the equipartition (a new form of the equipartition theorem [15,16]).

Thus, the fundamental aspect related to irreversibilities through the new concept of entropy production action seems promising. Furthermore, this new concept could contribute to the improvement of the global system analysis by conducting optimal dimension allocation. In this respect, finite physical dimensions analysis could be a complementary way to correlate with exergy analysis.

Further extensions of this work are foreseen in the near future.

6. Conclusions

Similarities and differences present in the literature regarding the optimization of energy, first law efficiency, and power of the modified Chambadal engine have been resituated and summarized since the publication of [12].

This approach allows for highlighting the evolution of the obtained results from the reversible Carnot engine case (thermostatics) to the endo-irreversible models related to the approaches of Novikov [6] and Ibrahim et al. [7] or to the entropy production method that we promote.

By generalizing a proposal from Esposito et al. [9] and defining the new concept of entropic action through a coefficient $C_I$ (Js/K) for the entropy production of transformations all along the cycle, we achieved a new form of power optimization different from the one of Curzon and Ahlborn, since the internal converter irreversibilities and the heat transfer irreversibility between the heat source and converter were accounted for.

The maximum work per cycle was obtained for the irreversible cycle case. It depended on the entropic action coefficient of the four transformations of the cycle $C_{IH}$, after which the power of the engine was sequentially optimized.

An optimal period of the cycle $\tau^*$ appeared, corresponding to the maximum mean power of the cycle. It generalized the recent published results [5] for a modified Chambadal engine.

This research continues to be developed by our team to obtain more general results.
Appendix A. Work per Cycle of the Modified Chambadal Engine with the Entropy Production Method

Figure A1. Carnot engine cycle with internal irreversibilities along the four transformations of the cycle, illustrated in a T-S diagram.

It results from Figure A1 that the various heats exchanged over the irreversible cycle (1–2–3–4) are expressed as follows:

- \( Q_H = T_H \Delta S_H \) is the heat received by the cycled medium from the hot source (energy expense), corresponding to the heat transfer at the hot side;
- \( Q_{conv} = T_H \Delta S_{conv} \), heat converted in mechanical energy during the isothermal process at \( T_H \), with corresponding production of entropy \( \Delta S_{IH} \) such that:
  \[
  Q_{conv} = T_H (\Delta S_H - \Delta S_{IH}).
  \]
- \( Q_C = T_0 \Delta S_C \), where \( \Delta S_C = \Delta S_S - \Delta S_{IC} \).
  Note that \( \Delta S_{IC} \) is the entropy production during the irreversible isotherm at \( T_0 \) and \( \Delta S_S \) is the entropy rejected to the sink such that \( Q_S = T_0 \Delta S_S \).
  Thus, the entropy balance over the cycle is
  \[
  \Delta S_{conv} + \Delta S_I = \Delta S_S \quad (A2)
  \]
  The total entropy production over the cycle \( \Delta S_I \) is represented by
  \[
  \Delta S_I = \Delta S_{IH} + \Delta S_{IEx} + \Delta S_{IC} + \Delta S_{ICo},
  \]
  where
\[ \Delta S_{\text{IH}} \] is the entropy production during the isothermal transformation at \( T_H \), \( \Delta S_{\text{IE}} \) is the entropy production during the adiabatic expansion from \( T_H \) to \( T_0 \), \( \Delta S_{\text{IC}} \) is the entropy production during the isothermal transformation at \( T_0 \), and \( \Delta S_{\text{ICO}} \) is the entropy production during the adiabatic compression from \( T_0 \) to \( T_H \).

The energy balance over the cycle for the system comprising the converter, the heat source, and the sink (with the source and sink as perfect thermostats) provides

\[ W = Q_{\text{conv}} - Q_S. \]  

(A4)

Various forms of mechanical energy are obtainable from this point by combining the preceding relations. Thus, one may express \( W \) as follows:

1. With \( \Delta S_{\text{conv}} \) as the reference entropy:

\[ W = T_H \Delta S_{\text{conv}} - T_0 \Delta S_S, \]  

(A5)

\[ W = (T_H - T_0) \Delta S_{\text{conv}} - T_0 \Delta S_I. \]  

(A6)

2. With \( \Delta S_S \) as the reference entropy:

\[ W = (T_H - T_0) \Delta S_S - T_H \Delta S_I. \]  

(A7)

3. With \( \Delta S_S \) or \( \Delta S_S \) as the reference entropy:

\[ W = T_H (\Delta S_H - \Delta S_{\text{IH}}) - T_C (\Delta S_C + \Delta S_{\text{ICO}}). \]  

(A8)

We prefer to choose between Equations (A6) and (A7). Note that Equation (A7) was the one used by Esposito et al. [9].

We use Equation (A6) here because it gave back known results, particularly the Gouy-Stodola theorem, with \( \Delta S_{\text{conv}} \) being a parameter. Thus, the maximum energy occurs when \( \Delta S_I = 0 \) such that

\[ W_{\text{endo}} = (T_H - T_0) \Delta S_{\text{conv}}. \]  

(A9)

This corresponds to the endo-reversible model of Chambadal.

In Section 3, we proposed a complete Chambadal model taking account entropy production all along the cycle.

**Appendix B. Work Optimization Relative to Time (Frequency)**

Using the Lagrange multipliers method with the frequencies \( f_i = \frac{1}{\tau_i} \) as variables, we get the following function:

\[
L(f_i) = \left( \sqrt{G_H T_{HS}} - \sqrt{(G_H + C_{IH}f_H) T_0} \right)^2
- T_0 (C_{IH}f_H + C_{IE}f_{IE} + C_{IC}f_C + C_{ICO}f_{ICO})
- \lambda \left( \frac{1}{f_H} + \frac{1}{f_{IE}} + \frac{1}{f_C} + \frac{1}{f_{ICO}} - \tau \right). \]

(A10)

The vector of optimal values is

\[ f_{\text{Ex}}^* = \sqrt{\frac{\lambda}{T_0 C_{IE}}} ; \quad f_C^* = \sqrt{\frac{\lambda}{T_0 C_{IC}}} ; \quad f_{ICO}^* = \sqrt{\frac{\lambda}{T_0 C_{ICO}}}, \]

(A11)

Additionally, the following is a non-linear equation to solve numerically for \( f_H^* \):

\[ f_H^2 = \lambda \sqrt{\frac{G_H + C_{IH}f_H}{G_H}} \frac{1}{\sqrt{T_{HS} T_0 C_{IH}}}. \]

(A12)
In the reasonable case of low irreversibility on the $T_H$ isotherm ($C_{IH} f_H \ll G_H$), a good approximation of $f_H^*$ is

$$f_H^* = \sqrt{\frac{\lambda}{\sqrt{T_HS T_0 C_{IH}}}}. \quad (A13)$$

The finitude constraint on $\tau_i$ allows for determining the $\sqrt{\lambda}$ expression as

$$\sqrt{\lambda} = \frac{N \sqrt{T_0}}{\tau}, \quad (A14)$$

where

$$N = \sqrt{\frac{T_0}{T_HS} C_{IH} + \sqrt{C_{IEx} \cdot \sqrt{C_{IC} + \sqrt{C_{ICO}}}}}. \quad (A15)$$

Finally, we get

$$\text{Max}_2 W \approx W_{\text{endo}} - T_0 \frac{N^2}{\tau}. \quad (A16)$$
