THE COLORED HOMFLYPT FUNCTION IS $q$-HOLONOMIC

STAVROS GAROUFALIDIS, AARON D. LAUDA, AND THANG T.Q. LÊ

Abstract. We prove that the HOMFLYPT polynomial of a link, colored by partitions with a fixed number of rows is a $q$-holonomic function. Specializing to the case of knots colored by a partition with a single row, it proves the existence of an $(a, q)$ super-polynomial of knots in 3-space, as was conjectured by string theorists. Our proof uses skew Howe duality that reduces the evaluation of web diagrams and their ladders to a Poincare-Birkhoff-Witt computation of an auxiliary quantum group of rank the number of strings of the ladder diagram. The result is a concrete and algorithmic web evaluation algorithm that is manifestly $q$-holonomic.

Key words and phrases: Knots, HOMFLYPT polynomial, colored HOMFLYPT polynomial, MOY graphs, webs, ladders, skew Howe duality, quantum groups, $q$-holonomic, super-polynomial, Chern-Simons theory.
1. Introduction

1.1. The colored Jones polynomial. The best-known quantum invariant of a knot or link $L$ in 3-space is the Jones polynomial $J_L$, which when properly normalized, is a Laurent polynomial in a variable $q$ with integer coefficients. Jones’s discovery of this polynomial marked the birth of quantum topology [Jon87], and shortly afterwards a plethora of quantum invariants of knots and links were discovered by Reshetikhin-Turaev; see [RT90] and also the books [Oht02, Tur94].

Although Jones’s definition of the Jones polynomial came from the von Neumann algebras and their subfactors, a connection of the Jones polynomial with the simplest non-abelian simple Lie algebra, $\mathfrak{sl}_2$, and its representations was soon discovered.

More precisely, given a simple Lie algebra $\mathfrak{g}$ and an irreducible (finite dimensional) representation $V$ (usually called a color, in the physics literature) and a knot $K$, the theory of ribbon category [RT90, Tur94] defines an invariant $J^\mathfrak{g}_K(V) \in \mathbb{Z}[q^{\pm 1}]$. The original construction of this invariant was a rational function in a fractional power of $q$, and a normalization of this invariant was shown in [Le00] to be an element of $\mathbb{Z}[q^{\pm 2}]$. The Reshetikhin-Turaev construction extends to framed oriented links as well, each component of which is colored by an irreducible representation of $\mathfrak{g}$.

Specializing to $\mathfrak{sl}_2$, and using the well-known fact that there is one irreducible representation $\mathfrak{h}_n$ of $\mathfrak{sl}_2$ of dimension $n + 1$ for every natural number $n$, it follows that a knot $K$ gives rise to a sequence of polynomials $J^\mathfrak{sl}_2_K(\mathfrak{h}_n) \in \mathbb{Z}[q^{\pm 1}]$ for $n = 0, 1, 2, \ldots$. This sequence, although infinite, satisfies some finiteness property which in particular implies that it is determined by finitely many initial terms (the number of initial terms depends on the knot though). More precisely, it was proven by two of the authors in [GL05] that for every knot
there exists a recursion
\begin{equation}
  c_d(q^n, q) J^{sl}_K(h_{n+d}) + c_{d-1}(q^n, q) J^{sl}_K(h_{n+d-1}) + \cdots + c_0(q^n, q) J^{sl}_K(h_n) = 0
\end{equation}
for all \( n \in \mathbb{N} \), where \( d \in \mathbb{N} \), \( c_j(u, v) \in \mathbb{Q}[u^\pm 1, v^\pm 1] \) for all \( j = 0, \ldots, d \) and \( c_d \neq 0 \). The recursion depends on the knot, and although it is not unique, it can be chosen canonically.

Aside from the above-mentioned finiteness statement, the importance of this minimal recursion (often called the \( \hat{A} \)-polynomial) is not a priori clear. Keeping in mind that PSL(2, \( \mathbb{C} \)) is the isometry group of orientation preserving isometries of 3-dimensional hyperbolic space, there are at least two connections between the \( \hat{A} \)-polynomial and hyperbolic geometry: (a) specializing the coefficients of the above recursion to \( q = 1 \), is conjectured to recover the defining polynomial for the SL(2, \( \mathbb{C} \))-character variety of the knot complement, restricted to the boundary torus of the knot complement. This so-called AJ Conjecture is one link of the colored Jones polynomial with the geometry of SL(2, \( \mathbb{C} \)) representations; see [Gar04, Lé06].

(b) Such a recursion can be used to numerically several terms of the asymptotics of the colored Jones polynomial at complex roots of unity, a fascinating story that connects quantum topology to hyperbolic geometry and number theory. For a sample of computations, the reader may consult [Garb, GZ].

Converting the above statement into a theorem and a proof requires additional work. To begin with, one needs to consider functions of several variables. For instance the \( sl_3 \)-colored Jones polynomial of a knot, or the \( sl_2 \)-colored Jones polynomial of a 2-component link is a function of two discrete variables. A definition of \( q \)-holonomic functions of several variables was given by Sabbah [Sab93] using the language of homological algebra. Sabbah used a theory of Hilbert dimension for modules over rings generated by \( q \)-commuting variables, and proved a key Bernstein inequality. A survey of Zeilberger’s and Sabbah’s work was given by two of the authors in [GL], where detailed proofs and examples of \( q \)-holonomic functions is discussed. A summary of the main definitions and properties of \( q \)-holonomic functions is given in Section 4.

1.2. The colored HOMFLYPT polynomial. Shortly after the discovery of the Jones polynomial, five groups independently discovered a two-variable polynomial, the HOMFLYPT polynomial \( W \) that takes values in the ring \( \mathbb{Q}(q)[x^\pm 1] \) [FYH+85, PT87]. Turaev [Tur88] showed that the latter unifies the quantum link invariants \( J_{L}^{sl_n}(h_1, \ldots, h_1) \), where \( h_1 = \mathbb{C}^n \) is the defining representation of \( sl_n \), as follows: for every \( n \geq 2 \) and every framed oriented link \( L \) whose components are colored by \( \mathbb{C}^n \), we have:
\[
  \tilde{J}_{L}^{sl_n}(h_1, \ldots, h_1) = W_L|_{x=q^n}.
\]
Here \( \tilde{J}_L \) is a normalized version of \( J_L \), see Section 2.
Let $\mathcal{P}$ denote the set of partitions $\lambda = (\lambda_1, \lambda_2, \ldots)$ where $\lambda_1 \geq \lambda_2 \geq \cdots \geq 0$ is a decreasing sequence of nonnegative natural numbers, all but finitely many zero. As usual, a partition is presented by a Young diagram. Let $\mathcal{P}_{n-1}$ be the set of partitions with at most $n - 1$ rows. Irreducible representations of $\mathfrak{sl}_n$ are parameterized by partitions in $\mathcal{P}_{n-1}$, and we will identify a partition $\lambda \in \mathcal{P}_{n-1}$ with its corresponding irreducible $\mathfrak{sl}_n$-module (which has highest weight $\lambda$, see [FH91]). With this identification, the partition $h_a$, which has one row and $a$ boxes, is the $a$-th highest symmetric power of $h_1$, and the partition $e_a$, which has one column and $a$ boxes, is the $a$-th external power of $h_1 = e_1$.

Wenzl [Wen90], generalizing Turaev’s result, showed that the $\mathfrak{sl}_n$-quantum link invariants interpolate a two-variable function in the following sense. If $L$ is an oriented framed link with $r$ ordered components and $\lambda_i$ are partitions with at most $\ell$ rows for $i = 1, \ldots, r$, then there exists a two-variable colored HOMFLYPT function $W_L(\lambda_1, \ldots, \lambda_r) \in \mathbb{Q}(q)[x^\pm 1]$ such that for all natural numbers $n$ with $n \geq \ell + 1$ we have:

$$\widetilde{J}^\mathfrak{sl}_n(\lambda_1, \ldots, \lambda_r) = W_L(\lambda_1, \ldots, \lambda_r)|_{x=q^n}.$$ 

A detailed definition of the HOMFLYPT polynomial and its colored version in terms of the HOMFLYPT polynomial of cables of the link is given in [ML03, MM08].

1.3. Statement of our results. The set $\mathcal{P}$ of all partitions has an involution defined by $\lambda \mapsto \lambda^\dagger$ which transposes columns and rows of a partition. The map $\iota_\ell : \mathbb{N}^\ell \to \mathcal{P}_\ell$ given by

$$\iota_\ell(n_1, \ldots, n_\ell) = (\lambda_1, \ldots, \lambda_\ell) \in \mathcal{P}_\ell, \quad \text{where} \quad \lambda_i = \sum_{j=1}^{n-i+1} n_j$$

is a bijection, and so is $\iota_\ell^\dagger : \mathbb{N}^\ell \to \mathcal{P}_\ell^\dagger$ (where $\mathcal{P}_\ell^\dagger$ is the set of all partitions with at most $\ell$ columns) defined by $\iota_\ell^\dagger(n_1, \ldots, n_\ell) = (\iota_\ell(n_1, \ldots, n_\ell))^\dagger$.

**Theorem 1.1.** Suppose $L$ is an oriented, framed link with $r$ ordered components and $\ell$ a nonnegative integer. Then, the following functions

$$W_L \circ (\iota_\ell)^r : \mathbb{N}^\ell \to \mathbb{Q}(q)[x^\pm 1], \quad W_L \circ (\iota_\ell^\dagger)^r : \mathbb{N}^\ell \to \mathbb{Q}(q)[x^\pm 1]$$

are $q$-holonomic.

**Corollary 1.2.** For a framed oriented knot $K$ colored with partitions with a single row, the sequence $W_K(h_a)$ for $a = 0, 1, 2, \ldots$ is $q$-holonomic.

Some special cases of the above corollary are known; see Cherednik [Che] for the case of torus knots, Wedrich [Wed] for the case of 2-bridge knots, and Kawagoe [Kaw] for some 2-bridge knots and some pretzel knots.

On the set of all functions from $\mathbb{N}$ to $\mathbb{Q}(x, q)$ define two operators $L, M$ by

$$(Lf)(a) = f(a + 1), \quad (Mf)(a) = q^a f(a).$$

Then $LM = qML$, and a recurrence for $f$ has the form $Pf = 0$, where

$$P = \sum_{j=0}^d c_j(q, x, M)L^j, \quad c_j(q, x, M) \in \mathbb{Z}[q, x, M].$$
When non-zero recurrence for $f$ exists, there are many of them, and there is a unique one, up to sign, such that (i) $d$ is minimal, (ii) the total degree in $q, x, M, L$ is minimal, and (iii) all the integer coefficients of $P$ are co-primes, see [Gar04, Lê06]. For a knot $K$, we denote such a minimal recurrence for $W_K(h_a)$ by $A_K(M, L, x, q)$.

Physicists have conjectured the existence of the 4-variable polynomial (see for instance the works [GSV05a, AV]), and have further conjectured that when we set $q = 1$, the corresponding 3-variable polynomial $A_K(M, L, Q, 1)$ is equal, after some universal (i.e., knot independent) change of variables with a 3-variable polynomial that comes out of knot contact homology [Ng08, AENV14]. In the physics literature, $A_K(M, L, Q, 1)$ is often called the $Q$-deformed $A$-polynomial of a knot and it appears in string theory in geometry of spectral curves, topological strings, matrix models, and M-theory dualities. There is a lot of literature on this polynomial following the pioneering work of Gukov, Fuji, Stosic, Sułkowski and others. For a detailed discussion, see [AV, DG10, DGR06, FGS13, FGSA12, GL05, GS14, GS12, GSV05b].

Remark 1.3. The proof of Theorem 1.1 implies the function $N \times N^{r\ell} \to \mathbb{Z}[q^{\pm 1}]$ defined by

$$(n, \vec{m}) \in N \times N^{r\ell} \mapsto (W_L \circ (u_{e})^r)(\vec{m})|_{x=q^n}$$

is $q$-holonomic in all $r\ell + 1$ variables. The latter was conjectured in [GvdV14].

1.4. An example. Suppose $K$ is the right-hand trefoil, see Figure 6, with 0 framing. Define

$$a_0 = x^4(x^2M^2 - 1)(q^6x^2M^4 - 1)$$
$$a_1 = q^7(q^4x^4M^4 - 1)(q^8x^4M^8 - q^4x^4M^4 + x^4M^4 - q^6x^2M^4 - q^2x^2M^4 - x^2M^2 + 1)$$
$$a_2 = -q^{18}x^2M^6(q^4M^2 - 1)(q^2x^2M^4 - 1).$$

Then for all $m \geq 0$,

(2) $$a_2W_K(h_{m+2}) + a_1W_K(h_{m+1}) + a_0W_K(h_m) = 0.$$

Remark 1.4. In [FGS13], a conjectural formula for the colored HOMFLYPT function $W_K(h_m)$ is given, for the case when $K$ is the left-hand trefoil (and other torus knots). Based on this conjectural formula, the authors of [FGS13], using a computer program of Zeilberger [PWZ96], found a recurrence formula for $W_K(h_m)$, which is different from (2) since another normalization was used. In Appendix C, we will give a proof of (2).

1.5. Plan of the proof. The quantum group invariants require familiarity with category theory, representation theory of quantum groups as well as understanding the accompanying graphical notation.

In Section 2 we discuss three categories $n\text{Rep}_\Lambda$, $n\text{Web}$ and $n\text{Lad}$ which are related to representations of quantum groups as well as to a diagrammatic description of links and their invariants. In Section 3 we discuss how to unify the $\mathfrak{sl}_n$ link invariants to one that is independent of $n$. In Section 4 we discuss the basic definitions, examples and properties of $q$-holonomic functions. In Section 5 we give the proof of Theorem 1.1. The proof is concrete and algorithmic, with a detailed example for the case of the right-handed trefoil given in Section 3.7. We summarize the steps here, using the notation of the proof.
(a) We start with a braid word representative $\beta$ whose closure $\text{cl}(\beta)$ is the link $L$. The corresponding braid has $m$ strands and a fixed number of letters. For the trefoil, this is given in equation (36).

(b) The link is now given by joining to the braid the bottom and top part of the closure consisting of cup/cap diagrams, respectively. We replace the bottom part by a monomial in some operators $E_i$, the braid word by a product of Lusztig braid operators $T_i(b)^{\pm 1}$ defined in section 3.4, and the top part by a monomial in some operators $F_j$. For the trefoil, this is given in equation (37).

(c) Each operator $T_i(b)^{\pm 1}$ is a sum (over the integers) of operators $E_i$ and $F_j$ (see equations (29a)-(29b)).

(d) The operators $E_i$ and $F_j$ satisfy the quantum group $q$-commutation relations given in equations (14a)-(14d), and using those we can sort the above expressions by moving all the $E$’s to the right and all the $F$’s to the left.

(e) The fact that the operators $E_i$ annihilate the last bit $1_\vartheta$, corresponding to the projection onto a highest weight determined from the link diagram, adds a product of delta functions in our sum.

(f) The requirement that all weights appearing in the sum are positive introduces Heaviside functions into the sum as explained in the proof of Proposition 5.2.

(g) This way, we obtain a multidimensional sum over the integers, whose summand is a product of extended $q$-binomial coefficients of linear forms (with integer coefficients) of the summation variables, times a sign raised to a linear form of the summation variables. These sums are always terminating. For the trefoil, this 6-dimensional sum is given in equation (39).

(h) We show in section 5.1 that such multisums are $q$-holonomic.

Hidden in the above algorithm is the quantum skew Howe duality [CKM14], which allows us to compute colored $\mathfrak{sl}_n$-invariants by evaluating ladder diagrams in $2m$ strands using an auxiliary quantum group based on the Lie algebra $\mathfrak{gl}_{2m}$. Steps (c)-(e) are exactly a Poincare-Birkhoff-Witt computation on $\mathfrak{gl}_{2m}$.

To avoid any confusion or misunderstanding, in an earlier article [Gara] one of the authors reduced the $q$-holonomicity of the colored HOMFLYPT polynomial to the $q$-holonomicity of the evaluation of MOY graphs, and observed that the latter would follow from the existence of a $q$-holonomic evaluation algorithm for MOY graphs. Unfortunately, such an algorithm based on simplifications of MOY graphs or web diagrams has yet to be found.

1.6. Computations and questions. With regards to computation of the 4-variable polynomial of a knot, there are several formulas for the HOMFLYPT polynomial of some links in the literature colored by partitions with one row, see for example [Kaw, NRZS12, IMM12b, IMM12a]. These formulas are manifestly $q$-holonomic, as follows by the fundamental theorem of WZ theory. Using these formulas and Wilf-Zeilberger theory, one can sometimes compute the 4-variable knot polynomial. For sample computations for the case of twist knots and some torus knots, see [NRZS12].

The next question is inaccessible with our methods. A positive answer would be useful in the study of LMOV (also known as BPS) invariants of links [LMV00]. First, using linearity extend the colored HOMFLYPT function to the case when the color of each link component
is a \( \mathbb{Z} \)-linear combination of Young diagrams. Let \( p_a = \sum_{k=0}^{a} (-1)^k (k, 1^{a-k}) \). Note that \((k, 1^{a-k})\) is a hook partition with one row with \( k \) boxes and one column with \( a-k \) boxes.

**Question 1.5.** Is it true that the HOMFLYPT polynomial of a knot colored by \( p_a \) is a \( q \)-holonomic function of \( a \)?

## 2. Categories, links and their invariants

Throughout the paper, \( n \) will denote a natural number greater than or equal to 2. We will denote by \( \mathbb{Q}(q^{1/n}) \) the field of rational functions in an indeterminate \( q^{1/n} \), and \( \mathbb{Q}(q) \) its subfield generated by \( q = (q^{1/n})^n \). Also \( \mathbb{Z}[q^{\pm 1}] \subset \mathbb{Q}(q) \) will denote the ring of Laurent polynomial in \( q \) with integer coefficients.

In this section we will discuss three categories \( n\text{Rep}_\Lambda, n\text{Web} \) and \( n\text{Lad} \) which are connected by functors

\[(3) \quad n\text{Lad} \xrightarrow{\Psi_q} n\text{Web} \xrightarrow{\Gamma_2} n\text{Rep}_\Lambda\]

A ring homomorphism \( f: \mathbb{Q}(q^{1/n}) \to \mathbb{Q}(q^{1/n}) \) (thought of as a homomorphism from the empty set to the empty set), is the multiplication by a scalar, and we denote this scalar by \( \text{ev}(f) \in \mathbb{Q}(q^{1/n}) \).

These categories are intimately related to diagrammatic descriptions of framed tangles and of quantum groups.

### 2.1. The quantized enveloping algebras \( U_q(\mathfrak{gl}_n) \) and \( U_q(\mathfrak{sl}_n) \)

Consider the lattice \( \mathbb{Z}^n \) with the standard Euclidean inner product \( \langle \cdot, \cdot \rangle \), and the root vectors

\[\alpha_i = (0, \ldots, 0, 1, -1, 0, \ldots, 0) \in \mathbb{Z}^n,\]

with 1 on the \( i \)-th position.

The quantized enveloping algebra \( U_q(\mathfrak{gl}_n) \) is the associative algebra over \( \mathbb{Q}(q) \) generated by \( L_i, i = 1, \ldots, n \) and \( E_i, F_i, i = 1, \ldots, n-1 \), subject to the relations

\[L^a L^b = L^{a+b}, \quad L_0 = 1\]
\[L^a E_j = q^{\gamma_j} a_j L_j^a, \quad L^a F_j = q^{-a_j} a_j F_j L^a\]
\[E_i^{(2)} E_{i+1} = E_i E_{i+1} E_i + E_{i+1} E_i^{(2)} = 0 = F_i^{(2)} F_{i+1} - F_i F_{i+1} F_i + F_{i+1} F_i^{(2)}\]
\[E_i F_j - F_j E_i = \delta_{ij} \frac{K_i - K_i^{-1}}{q - q^{-1}}\]
\[E_i E_j = E_j E_i, \quad F_i F_j = F_j F_i \quad \text{for } |i-j| > 1.\]

Here \( L^a = L_1^{a_1} \ldots L_n^{a_n} \) for \( a = (a_1, \ldots, a_n) \in \mathbb{Z}^n \), \( K_i = L_i L_i^{-1} \), and

\[E_i^{(r)} = E_i^r / [r]!, \quad F_i^{(r)} = F_i^r / [r]!, \quad \text{where } [r]! = \prod_{j=1}^{r} \frac{q^j - q^{-j}}{q - q^{-1}}.\]

There is a structure of a Hopf algebra on \( U_q(\mathfrak{gl}_n) \) with the co-product and the antipode, see e.g. [Jan96, CP94, Lus10].
The quantized enveloping algebra $U_q(\mathfrak{sl}_n)$ is the subalgebra of $U_q(\mathfrak{g}l_n)$ generated by $E_i, F_i, K_i^{\pm 1}, i = 1, \ldots, n - 1$. Then $U_q(\mathfrak{sl}_n)$ inherits a Hopf algebra structure from that of $U_q(\mathfrak{g}l_n)$.

A weight of $U_q(\mathfrak{g}l_n)$ (resp., $U_q(\mathfrak{sl}_n)$) is an element $a \in \mathbb{Z}^n$ (resp., an element $a \in \mathbb{Z}^n$ such that $\sum a_i = 0$). A $U_q(\mathfrak{sl}_n)$-module $V$ is called a weight module (or perhaps better, a weighted module) if $V = \bigoplus_a V_{[a]}$, where each $a$ is a $U_q(\mathfrak{sl}_n)$-weight and

$$V_{[a]} = \{v \in V \mid K_i(v) = q^{(a_i, a)}v\}.$$ 

For a partition $\lambda = (l_1, \ldots, l_\ell)$ with $l_1 \geq l_2 \geq \cdots \geq l_\ell > 0$ we call $\ell = \text{length}(\lambda)$ the length of $\lambda$ and $|\lambda| = \sum_i l_i$ the weight of $\lambda$. Denote by $\lambda^\dagger$ the conjugate of $\lambda$, which is the partition whose Young diagram is the transpose of that of $\lambda$. For a thorough treatment of partitions, see [Mac95]. Finite-dimensional irreducible weight $U_q(\mathfrak{sl}_n)$-modules are parameterized by partitions $\lambda \in \mathcal{P}_{n-1}$, i.e. partitions of length $\leq n - 1$, see e.g [CP94, Jan96]. For every $\lambda \in \mathcal{P}_{n-1}$ denote by $V_\lambda$ the corresponding irreducible weight $U_q(\mathfrak{sl}_n)$-module.

2.2. The category of $U_q(\mathfrak{sl}_n)$-modules and link invariants. The category $n\text{Rep}$ of finite-dimensional weight $U_q(\mathfrak{sl}_n)$-modules is a ribbon category [Tur94], where the braiding comes from the universal $R$-matrix. To be precise, one needs to extend the ground field to $\mathbb{Q}(q^{1/n})$ so that the braiding and the ribbon element can be defined.

By the theory of ribbon categories, for a framed oriented link $L$ in 3-space with $r$ ordered components and $r$ objects $V_1, \ldots, V_r$ of $n\text{Rep}$, one can define an invariant

$$J^\mathfrak{sl}_n(V_1, \ldots, V_r) \in \mathbb{Q}(q^{1/n}).$$

If $\lambda_1, \ldots, \lambda_r \in \mathcal{P}_{n-1}$, we use the notation

$$J^\mathfrak{sl}_n(\lambda_1, \ldots, \lambda_r) = J^\mathfrak{sl}_n(V_{\lambda_1}, \ldots, V_{\lambda_r}).$$

It is known that a properly normalized version of $J^\mathfrak{sl}_n(V_1, \ldots, V_r)$ belongs to $\mathbb{Z}[q^{\pm 2}]$, see [MW98, Lê00]. A special case of this integrality phenomenon is the following. Let $\ell_{ij}$ be the linking number between the $i$-th and the $j$-component of $L$, with $\ell_{ii}$ the framing of the $i$-th component. Define

(4) $$J^\mathfrak{sl}_n(\lambda_1, \ldots, \lambda_r) = q^{k_1} \sum_{i,j} \ell_{ij} |\lambda_i| |\lambda_j| J^\mathfrak{sl}_n(\lambda_1, \ldots, \lambda_r).$$

Then we have

(5) $$J^\mathfrak{sl}_n(\lambda_1, \ldots, \lambda_r) \in \mathbb{Z}[q^{\pm 1}].$$

Not only is $J^\mathfrak{sl}_n(\lambda_1, \ldots, \lambda_r)$ a Laurent polynomial in $q$, but it also enjoys the following stability (with respect to the rank $n$) property.

**Proposition 2.1** ([Wen90]). There exists an invariant $W_L(\lambda_1, \ldots, \lambda_r) \in \mathbb{Q}(q)[x^{\pm 1}]$ such that for any $n$ greater than the length of any of $\lambda_j$, we have

$$W_L(\lambda_1, \ldots, \lambda_r)|_{x=q^n} = J^\mathfrak{sl}_n(\lambda_1, \ldots, \lambda_r).$$

$W_L$ is usually called the colored HOMFLYPT function. The theorem was first proved by Wenzl using quantum group theory. For a detailed proof using skein theory see [Luk01, Theorem 11.4.18]. The theorem also follows from our proof of Theorem 1.1 below. For the simplest case, when all partitions have one box, Proposition 2.1 was first proved by Turaev [Tur88].
Remark 2.2. The integrality (5) shows that the polynomial $P = W_L(\lambda_1, \ldots, \lambda_r) \in \mathbb{Q}(q)[x^{\pm 1}]$ has the property that $P|_{x=q^n} \in \mathbb{Z}[q^{\pm 1}]$ for all integer $n > 1$. Such a polynomial $P \in \mathbb{Q}(q)[x^{\pm 1}]$ is called $q$-integral and is studied in [BCL14, Sec. 2.3].

Remark 2.3. Our $W_L(\lambda_1, \ldots, \lambda_r)$ is equal to $P(L^*(Q_{\lambda_1}, \ldots, Q_{\lambda_r}))$ in the notation of [MM08, Section 6], with our $q$ and $x$ equal to respectively $s$ and $v^{-1}$ there.

2.3. Properties of the colored HOMFLYPT polynomial. Let $\Lambda$ be the free $\mathbb{Q}$-vector space with basis the set $\mathcal{P}$ of all Young diagrams, including the empty one. Suppose $L$ is a framed oriented link with $r$ ordered components. The invariant $W_L(\lambda_1, \ldots, \lambda_r)$ can be extended to a $\mathbb{Q}$-multi-linear map $W_L : \Lambda^r \to \mathbb{Q}(q)[x^{\pm 1}]$.

There is a $\mathbb{Q}$-algebra structure on $\Lambda$ which makes it isomorphic to the algebra of symmetric functions, see e.g. [Mac95]. Under this isomorphism, a Young diagram $\lambda$ is mapped to the Schur function $S_\lambda$ corresponding to $\lambda$.

We collect here some well-known properties of the quantum invariant $W_L$.

Proposition 2.4. Let $L$ be a framed oriented link in the 3-space with $k$ ordered components. (a) Suppose $L'$ is the same $L$ with the components renumbered by a permutation $\sigma$ of \{1, $\ldots$, $k$\}. Then

$$W_L'(\lambda_1, \ldots, \lambda_r) = W_L(\lambda_{\sigma 1}, \ldots, \lambda_{\sigma r}).$$

(b) Suppose $\Delta L$ is the result of replacing the first component of $L$ by two copies of its parallel push-off (using the framing). Then

$$W_{\Delta L}(\lambda_1', \lambda_2', \lambda_2, \ldots, \lambda_r) = W_L(\lambda_1, 2, \lambda_2, \ldots, \lambda_r).$$

(c) We have:

$$W_L(\lambda_1, \ldots, \lambda_r) = W_L(\lambda_1^*, \ldots, \lambda_r^*)|_{q \to -q^{-1}}.$$

Parts (a) and (b) follow from the corresponding properties for $J_L$, see [Tur94]. While (a) is trivial, (b) follows from the hexagon equation of the braiding in the braided category. Part (c) is well-known and has been discussed in many papers, see e.g. [LMV00, Equ. 4.41]. For completeness, we give proofs of parts (b) and (c) in Appendix B.

2.4. The category $n\text{Rep}_\Lambda$. Let $e_a$ be the partition whose Young diagram is a column with $a$ boxes, i.e. $e_a = (1^a)$ in the standard notation of partitions. The $U_q(\mathfrak{sl}_n)$-module $V_{e_a}$ with $1 \leq a \leq n - 1$ is called a fundamental $U_q(\mathfrak{sl}_n)$-module. We also use $e_0$ to denote the empty Young diagram, which corresponds to the trivial $U_q(\mathfrak{sl}_n)$-module.

Let $n\text{Rep}_\Lambda$ be the full subcategory of $n\text{Rep}$ whose objects are those isomorphic to tensor products of the fundamental $U_q(\mathfrak{sl}_n)$-modules. Then $n\text{Rep}_\Lambda$ inherits a ribbon category structure from $n\text{Rep}$.

The advantage of $n\text{Rep}_\Lambda$ is that it has a remarkable presentation using planar diagrams called spider webs described in the next section. Since $n\text{Rep}$ is the idempotent completion of $n\text{Rep}_\Lambda$, we don’t loose much working with $n\text{Rep}_\Lambda$. 
2.5. **The category \( n \text{Web} \).** We describe here the category \( n \text{Web} \) of \( \mathfrak{sl}_n \)-webs, following Cautis-Kamnitzer-Morrison [CKM14]. Recall that a pivotal monoidal category is a category with tensor products and a coherent notion of duality in which the double dual functor is naturally isomorphic to the identity. The morphisms and the relations among morphisms of such categories afford a diagrammatic description using planar diagrammatics. They are essentially equivalent to the description of the Temperley-Lieb algebra for \( n = 2 \) and to Kuperberg’s spider webs [Kup96] (for \( n = 3 \)) and the planar algebras of Jones [Jon]. They are also closely related to the MOY graphs of Murakami, Ohtsuki, and Yamada [MOY98]. Standard references for pivotal categories include the books [Tur94, Chpt.XI], [KRT97] as well [EGNO15, Chpt.4.7].

An \( n \)-web is a compact subset \( Z \) of the horizontal strip \( \mathbb{R} \times [0,1] \) with additional data satisfying (i)-(iii).

(i) Each connected component of \( X \) is either an oriented circle or a directed graph (i.e. a finite 1-dimensional CW-complex) where the degree of each vertex is 1, 2, or 3. Every circle component and every edge is labeled by an integer in \( [1, n-1] \).

(ii) The set \( \partial Z \) of univalent vertices of \( Z \) is in the union of the top and bottom lines of the strip and \( Z \setminus \partial Z \) is in the interior of the strip.

(iii) Up to isotopy there are 2 types of trivalent vertices and 2 types of bivalent vertices as in the following figure (with labeling of edges attached to the vertex):

![Diagram](image)

The third and the fourth graphs depict bivalent vertices but not trivalent vertices, as the small tag there is not officially an edge. The tag provides a distinguished side and makes the bivalent vertices not rotationally symmetric.

We will declare isotopic webs to be equal.

Let \( \partial_- Z = (i_1^{\varepsilon_1}, \ldots, i_k^{\varepsilon_k}) \), where \( i_1, \ldots, i_k \) are the labels of the edges ending on the bottom line listed from left to right, and \( \varepsilon_j = + \) if the orientation at the \( j \)-th ending point is upwards and \( \varepsilon_j = - \) otherwise. One defines \( \partial_+ Z \) exactly the same way, using the top line instead of the bottom line.

The category \( n \text{Web} \) is the pivotal monoidal \( \mathbb{Q}(q^{1/n}) \)-linear category whose objects are sequences in the symbols \( \{1^\pm, \ldots, (n-1)^\pm\} \). Given objects \( a, b \) of \( n \text{Web} \), the set of morphisms \( \text{Hom}_{n \text{Web}}(a, b) \) is the set of \( \mathbb{Q}(q^{1/n}) \)-linear combinations of \( n \)-webs \( Z \) such that \( \partial_- Z = a, \partial_+ Z = b \), subject to certain local relations described in [CKM14, Section 2.2]. In [CKM14], our \( n \text{Web} \) is denoted by \( \text{Sp}( \mathfrak{sl}_n ) \). The tensor product \( Z_1 \otimes Z_2 \) is obtained by placing \( Z_2 \) to the right of \( Z_1 \). The composition \( Z_1 Z_2 \) is the result of placing \( Z_1 \) atop \( Z_2 \), after an isotopy to make the top ends of \( Z_2 \) match the bottom ends of \( Z_1 \).

For example, the first diagram in (7) represents a morphism from \( a^+ \otimes b^+ = (a^+, b^+) \rightarrow (a + b)^+ \), and the second one represents a morphism from \( a^- \otimes b^- \rightarrow (a + b)^- \).

The monoidal unit \( n \text{Web} \) is the empty sequence. The planar isotopy condition implies that the object \( a^+ \) is dual to the object \( a^- \). The cap and cup morphisms
The colored Homflypt function is \( q \)-holonomic \( (8) \),

give rise to maps \( a^+ \otimes a^- \to \emptyset \) and \( \emptyset \to a^- \otimes a^+ \) that realize this duality.

For simplicity we allow diagrams to carry labels of 0 and \( n \) with the understanding that \( n \)-labelled edges connected to a trivalent vertex should be deleted and replaced by a tag as in the cap and cup diagrams:

\[
\begin{align*}
\begin{array}{c}
\text{Diagram 9:} \\
\text{Diagram 9:}
\end{array}
\end{align*}
\]

and the remaining edges and loops labeled 0 or \( n \) should be deleted.

Note that the cap and cup diagrams coming from the duality \( a^+ \) with \( a^- \) arising from the pivotal structure do not require tags.

The followings are consequences of the relations among generators of \( \mathfrak{sl}_n \)-webs:

\[
\begin{align*}
\begin{array}{c}
\text{Diagram 10:} \\
\text{Diagram 10:}
\end{array}
\end{align*}
\]

Remark 2.5. The tags appearing in \( n \)-web (which do not appear in [MOY98]) play an important role keeping track of the fact that while \( (V_{e_a})^* \) is isomorphic to \( V_{e_{n-a}} \), this isomorphism is not canonical. The tags in \( \mathfrak{sl}_n \)-webs keep track of these isomorphisms and contribute signs that would have otherwise been missed by wrongly identifying the dual of \( a^+ \) with \( (n-a)^+ \).

2.6. An equivalence between \( n \text{Web} \) and \( n \text{Rep}_\Lambda \). The main result of [CKM14] is the construction of an equivalence, which is a \( \mathbb{Q}(q^{1/n}) \)-linear pivotal functor,

\[
\Gamma_n : n \text{Web} \to n \text{Rep}_\Lambda
\]

defined on objects by \( \Gamma_n(a^+) = V_{e_n} \) and \( \Gamma_n(a^-) = (V_{e_a})^* \). The ribbon structure of \( n \text{Rep}_\Lambda \) can be pulled back to make \( n \text{Web} \) a ribbon category. In particular, we have a braiding \( X_{a,b} : a \otimes b \to b \otimes a \) for any two objects \( a, b \) of \( n \text{Web} \). For simple objects \( a, b \in [1, n-1] \) we
use the diagrams with crossings as in Figure 1 to denote the braiding \( X_{a,b} \) its inverse \( X_{b,a}^{-1} \). The braiding allows us to introduce crossings in diagrams representing morphisms of \( n\text{Web} \).

\[
\begin{align*}
X_{a,b} &= \begin{array}{c}
\text{Diagram}
\end{array} & X_{b,a}^{-1} &= \begin{array}{c}
\text{Diagram}
\end{array}
\end{align*}
\]

**Figure 1.** The braiding \( X_{a,b} \) (left) and its inverse \( X_{b,a}^{-1} \).

Suppose \( D \) is a link diagram in the plane in general position with respect to the height function, whose components are labeled by integers in \([0, n - 1]\). Then \( D \) defines morphism in the category \( n\text{Web} \) from \( \emptyset \) to \( \emptyset \). Since \( \text{Hom}_{n\text{Web}}(\emptyset, \emptyset) = \mathbb{Q}(q^{1/n}) \), the morphism \( D \) is determined by the scalar \( \text{ev}(D) \in \mathbb{Q}(q^{1/n}) \). The equivalence \( \Gamma_n \) shows that this scalar \( \text{ev}(D) \) is equal to the invariant \( J^{sl_n}(e_{a_1}, \ldots, e_{a_k}) \), i.e.

\[
(12) \quad J^{sl_n}(e_{a_1}, \ldots, e_{a_k}) = \text{ev}(D),
\]

where \( L \) is the framed link whose blackboard diagram is \( D \) and \( a_1, \ldots, a_k \) are the labels of the components of \( L \).

### 2.7. The Ladder Category.

We give the definition of ladder category \( \text{Lad}_m \), which a diagrammatic presentation of Lusztig’s idempotent form \( \tilde{U}_q(\mathfrak{gl}_m) \) of the quantum group \( U_q(\mathfrak{gl}_m) \). Typically, \( \tilde{U}_q(\mathfrak{gl}_m) \) is regarded as a \( \mathbb{Q}(q) \)-algebra where the unit is replaced by a system of mutually orthogonal idempotents \( 1_a \) indexed by the weight lattice of \( \mathfrak{gl}_m \). In [CKM14], using the quantum skew-Howe duality, they showed that there is a braided monoidal functor from the ladder category to the category \( n\text{Web} \). We explain how to use this result to calculate quantum \( U_q(\mathfrak{sl}_n) \)-invariants of links using ladders.

**A ladder \( Z \) with \( m \) sides** is a uni-trivalent graph drawn in the strip \( \mathbb{R} \times [0, 1] \), with

(i) \( m \) parallel vertical lines running from the bottom line to the top line of the strip, oriented upwards,

(ii) some number of oriented horizontal lines in the interior of the strip \( \mathbb{R} \times [0, 1] \), called steps, connecting adjacent sides,

(iii) a labeling of each interval (steps or segments of sides) by integers, such that the signed sum of the labels at each trivalent vertex is zero. Here the sign of each incoming vertex is positive, and the sign of each outgoing vertex is negative.

Let \( \partial_- Z \) (resp. \( \partial_+ Z \)) be the sequence of labels appearing on the bottom (resp. top) edge of the strip. Then \( \partial_- Z, \partial_+ Z \in \mathbb{Z}^m \) are considered as weights of \( U_q(\mathfrak{gl}_m) \).

The category \( \text{Lad}_m \) is the \( \mathbb{Q}(q) \)-linear category whose set of objects is \( \mathbb{Z}^m \). Given two objects \( a, b \), the morphisms \( \text{Hom}_{\text{Lad}_m}(a, b) \) is the set of all \( \mathbb{Q}(q) \)-linear combinations of ladders \( Z \) with \( m \) sides such that \( \partial_- Z = b, \partial_+ Z = a \), subject to the relations described in Equations (14a)-(14e) below.
Composition of morphisms is given by vertical concatenation of ladders. Note that $\textbf{Lad}_m$ does not have dual objects and hence is not pivotal.

For an object $a = (a_1, \ldots, a_m)$ of $\textbf{Lad}_m$ and for $i$ such that $0 \leq i \leq m - 1$, and $r \in \mathbb{N}$ let $E_i^{(r)}1_a$ and $F_i^{(r)}1_a$ denote the following ladders:

\[
E_i^{(r)}1_a := \cdots \quad a_i + r \quad a_{i+1} - r \quad \cdots \in \text{Hom}_{\textbf{Lad}_m}(a, a + r\alpha_i)
\]

\[
F_i^{(r)}1_a := \cdots \quad a_i - r \quad a_{i+1} + r \quad \cdots \in \text{Hom}_{\textbf{Lad}_m}(a, a - r\alpha_i)
\]

Here and in what follows, we draw the steps of a ladder using slightly slanted lines instead of horizontal lines such that the orientation of the step is upwards. With this convention we do not have to mark the orientation in a ladder diagram, since all segments are oriented upwards.

Comparing the sequence at the end of these ladders it is clear that

\[
E_i^{(r)}1_a = 1_{a + r\alpha_i} E_i^{(r)}1_a = 1_{a + r\alpha_i} E_i^{(r)}1_a, \quad F_i^{(r)}1_a = 1_{a - r\alpha_i} F_i^{(r)}1_a = 1_{a - r\alpha_i} F_i^{(r)}1_a,
\]

When the specific weight is clear we will write $E_i$ instead of $E_i1_a$ and $F_i$ instead of $F_i1_a$. For example, $F_i^{(r)} E_j^{(s)}1_a$ means $F_i^{(r)}1_{a + s\alpha_j} E_j^{(s)}1_a$. 

**Figure 2.** A morphism in $\textbf{Lad}_3$. 

---

THE COLORED HOMFLYPT FUNCTION IS $q$-HOLONOMIC 13
With this convention, the relations of the morphisms of $\text{Lad}_m$ are given by

\begin{align*}
(14a) & \quad E_i^{(r)} F_i^{(s)} 1_a = \sum_{t=0}^{\min(r,s)} \left\langle a, \alpha_i \right\rangle + r - s \right\rangle F_i^{(s-t)} E_i^{(r-t)} 1_a \\
(14b) & \quad E_i^{(r)} F_j^{(s)} 1_a = F_j^{(s)} E_i^{(r)} 1_a \quad \text{if } i \neq j \\
(14c) & \quad E_i^{(r)} E_j^{(s)} 1_a = E_j^{(s)} E_i^{(r)} 1_a \quad \text{if } |i - j| > 1, \text{ likewise for } F's \\
(14d) & \quad E_i^{(s)} E_i^{(r)} 1_a = \left[ \frac{r+s}{r} \right] E_i^{(r+s)} 1_a \quad \text{and likewise for } F's \\
(14e) & \quad E_i E_j E_i^{(r)} 1_a = (E_i^{(2)} E_j + E_j E_i^{(2)}) 1_a \quad \text{if } |i - j| = 1, \text{ likewise for } F's.
\end{align*}

for all $r, s \in \mathbb{N}$, $0 \leq i \leq m - 1$ and $a \in \mathbb{Z}^m$.

Recall $\langle a, \alpha_i \rangle = a_i - a_{i+1}$ is the standard inner product on $\mathbb{Z}^m$, and the quantum integers, factorial and binomial coefficients are defined by

\begin{align*}
(15a) & \quad [r] = \frac{q^r - q^{-r}}{q - q^{-1}}, \quad r \in \mathbb{Z} \\
(15b) & \quad [r]! = \prod_{k=1}^{r} [k], \quad r \geq 0 \\
(15c) & \quad \left[ \begin{array}{c} r \\ s \end{array} \right] = \left\{ \begin{array}{ll} \prod_{k=r-s+1}^{r} [k] \\ [s]! \end{array} \right\} \quad r, s \in \mathbb{Z}, \quad s \geq 0 \\
& \quad \left[ \begin{array}{c} r \\ s \end{array} \right] = \left\{ \begin{array}{ll} 0 \\ [s]! \end{array} \right\} \quad s < 0.
\end{align*}

**Remark 2.6.** If $k$ is a field and $C$ is a $k$-linear category, it gives rise to an algebra $A(C)$ whose underlying vector space is the direct sum of all Hom spaces $\oplus_{a,b} \text{Hom}(a, b)$. The product of $x \in \text{Hom}(b, a)$ and $y \in \text{Hom}(b', a')$ defined to be zero unless $b = a'$, in which case the product is defined to be the composite $xy$. $A(C)$ is a $k$-algebra without unit, in general. Since the relations (14a)–(14e) are the defining relations Lusztig’s idempotent algebra $\hat{U}_q(\mathfrak{gl}_m)$, $A(\text{Lad}_m) \cong \hat{U}_q(\mathfrak{gl}_m)$.

### 2.8. The Schur quotient, the highest weight $\vartheta$, and evaluation.

Fix positive integers $m$ and $n$. The Schur quotient $n\text{Lad}_m$ is defined to be the $\mathbb{Q}(q^{1/n})$-linear category with set of objects all $a = (a_1, \ldots, a_m) \in \mathbb{Z}^m$ such that $a \in [0, n]^m$, i.e. $0 \leq a_i \leq n$ for all $i$. The algebra of morphisms of $n\text{Lad}_m$ is the quotient of the algebra of morphisms of $\text{Lad}_m$, with ground field extended to $\mathbb{Q}(q^{1/n})$, by the two-sided ideal generated by all $1_a$ with $a \notin [0, n]^m$.

For example, $E_i^{(r)} 1_a$ is always 0 in $n\text{Lad}_m$ when $r > n$.

Let

\begin{equation}
\vartheta(n, m) := (n^m, 0^m) \in \mathbb{Z}^{2m}
\end{equation}

often abbreviated by $\vartheta$. Considered as an object of $n\text{Lad}_{2m}$, $\vartheta$ is a highest weight element for $n\text{Lad}_{2m}$, in the sense that for every $i = 1, \ldots, 2m - 1$, we have

\begin{equation}
E_i 1_{\vartheta} = 0 = 1_{\vartheta} F_i 1_{\vartheta + \alpha_i} = 0.
\end{equation}
This is because $\vartheta + \alpha_i$ has entries outside $[0, n]$. It follows that the algebra of endomorphisms of $\vartheta$ is isomorphic to the ground field $\mathbb{Q}(q^{1/n})$. In other words, we have an evaluation map
\begin{equation}
\text{ev}_n : \text{Hom}_{n\text{Lad}_m}(\vartheta, \vartheta) \simeq \mathbb{Q}(q^{1/n}), \quad x = \text{ev}(x)1_\vartheta.
\end{equation}

2.9. **Braiding for ladders.** The category $n\text{Lad}_m$ does not have a tensor product and hence is not a monoidal category. However, $\text{Lad} := \bigoplus_{m=1}^{\infty} n\text{Lad}_m$ is monoidal. This category doesn’t have duals since all webs are directed upwards. But it is a braided monoidal category, as follows. The objects of $n\text{Lad}$ are sequences $a = (a_1, \ldots, a_m)$ of integers $a_i \in [0, n]$. Given two objects $a = (a_1, \ldots, a_m)$ and $b = (b_1, \ldots, b_p)$, $\text{Hom}_{n\text{Lad}}(a, b) = \text{Hom}_{n\text{Lad}_m}(a, b)$ if $p = m$ and $0$ otherwise.

The tensor product of objects $a \otimes b$ is the horizontal concatenation of $a$ and $b$ from left to right, and similarly for morphisms.

In [CKM14, Section 6] it is shown that $n\text{Lad}$ admits a braided monoidal category structure, i.e. it has a braiding, which is a system of natural isomorphisms $X_{a,b} : a \otimes b \to b \otimes a$ satisfying the hexagon equations [RT90, Tur94]. The braiding for $n\text{Lad}$ is constructed using Lusztig’s braid elements [Lus10].

We also use the diagrams with crossings in Figure 1 to denote the braiding $X_{a,b}$ and its inverse $X_{a,b}^{-1}$ in the category $n\text{Lad}_m$.

When $\beta$ is a braid on $m$ strands and $a = (a_1, \ldots, a_m) \in \mathbb{Z}^m$, let $\beta 1_a \in \text{Hom}_{n\text{Lad}_m}(\beta(a), a)$ be the morphism described in Figure 3. Here $\beta(a)$ is obtained from $a$ by applying the permutation corresponding to the braid $\beta$. For example, $\sigma_1 1_a$ and $\sigma_1^{-1} 1_a$, where $\sigma_i, \sigma_i^{-1}$ are the $i$-th standard braid generator and its inverse, are depicted in Figure 3.

![Figure 3](image)

**Figure 3.** The morphisms $\beta 1_a$, $\sigma_1 1_a$, and $\sigma_1^{-1} 1_a$

Then $\sigma_i^{\pm 1} 1_a \in \text{Hom}_{n\text{Lad}_m}(\sigma_i(a), a)$. We record here the formula for the braiding from [CKM14]:
\begin{align}
\sigma_i 1_a &= (-1)^{a_i + a_{i+1}} q^{a_i - a_{i+1}} \sum_{s > 0, r} \frac{s}{s-r} \langle r \rangle F^{(r)}_i F^{(s)}_i 1_a \\
\sigma_i^{-1} 1_a &= (-1)^{a_i + a_{i+1}} q^{-a_i + a_{i+1}} \sum_{s > 0, r} \frac{s}{s-r} \langle r \rangle F^{(r)}_i F^{(s)}_i 1_a
\end{align}
Note that the right hand sides are finite sums, since \( F_i^{(r)} \) and \( E_i^{(r)} \) are 0 for \( r > n \). Also \( \sigma_i^{-1} a \) is obtained from \( \sigma_i a \) by the involution \( q \to q^{-1} \).

**Remark 2.7.** Originally Lusztig [Lus10, 5.2.1] defined the braiding and its inverses using triple product formulas. The simplification of Lusztig’s formula’s to double products in equations (19)–(20) was first observed for \( q = 1 \) by Chuang and Rouquier [CR08]. For general \( q \), a proof of this simplification can be found in [CKM14, Lem.6.1.1].

### 2.10. From ladders to webs.

In [CKM14, Section 5] it is proved that there is a \( \mathbb{Q}(q^{1/n}) \)-linear functor

\[
\Psi_{n,m} : n\text{Lad}_m \to n\text{Web}
\]

defined as follows. For an object \( a = (a_1, \ldots, a_m) \) of \( n\text{Lad}_m \), \( \Psi_{n,m}(a) \) is obtained from \( a \) by deleting 0s and ns from \( a \) and converting \( k \) to \( k^+ \). For a morphism \( f \) of \( n\text{Lad}_m \) which is a ladder, \( \Psi_{n,m}(f) \) is the same \( f \) considered as an \( n \)-web, using the convention about labelings 0 and \( n \). This means edges connected to the label 0 should be deleted from the diagrams and those connected to the label \( n \) should be truncated to the “tags” depicted in the last two diagrams in equation (7) as explained in (9). The existence of \( \Psi_{n,m} \) is a consequence of the quantum skew-Howe duality.

The functors \( \Psi_{n,m} : n\text{Lad}_m \to n\text{Web}, \) with all \( m \), piece together to give a functor \( \Psi_n : n\text{Lad} \to n\text{Web} \). By Theorem [CKM14, Theorem 6.2.1], \( \Psi_n \) is a braided monoidal functor.

---

**Figure 4.** The standard closure of a braid \( \beta \) with 4 strands.

Suppose \( \beta \) is a braid on \( m \) strands. We view \( \beta \) as a diagram with crossings in the standard plane with strands oriented upwards. Let \( \text{cl}(\beta) \) be the link diagram obtained by closing \( \beta \) in the standard way (see Figure 4) and \( L = L(\beta) \) be the corresponding framed link. Assume \( L \) has \( k \) ordered components which are labeled by integers \( a_1, \ldots, a_k \in [1, n - 1] \). Let \( a = (a_1, \ldots, a_k) \). Let \( b_1, \ldots, b_m \) be the induced labeling of strands of \( \beta \) from left to right (at the bottom of \( \beta \)). Of course each \( b_i \) is one of the \( a_j \)’s.
Let $\text{Lcl}(\beta, a)$, called the \textit{ladder closure of $\beta$}, be the endomorphism of $\vartheta(n, m)$ in the category $n\text{Lad}_{2m}$ given by the ladder described in Figure 5. Here the labels of the strands of the braids are $b_1, \ldots, b_m$ which are determined by the labels $a_1, \ldots, a_k$ of the link $L$. All the dashed vertical lines of the $m$ left sides are labeled by $n$ while all the dashed vertical lines of the $m$ right sides are labeled by $0$. Then the remaining labels are uniquely determined by the rule that the signed sum at every trivalent vertex is $0$.

Figure 5. The ladder closure of a braid $\beta$ with 4 strands, with labels. Here $c_i = n - b_i$.

**Proposition 2.8.** We have

$$\text{ev}(\text{Lcl}(\beta, a)) = J_L(e_{a_1}, \ldots, e_{a_k}).$$

**Proof.** Let $L$ denote the closure of $\beta$. $L$ is a link colored by $a$. Identities (10) and (11) show that

$$\Psi_n(L, a) = \text{cl}(\beta, a).$$
Since $\Psi_n$ is a $\mathbb{Q}(q^{1/n})$-linear braided functor, we have
\[
\operatorname{ev}(\text{cl}(\beta, a)) = \operatorname{ev}(\Psi_n(L, a)) = J_L(e_{a_1}, \ldots, e_{a_k}).
\]
where the second identity follows from (12). \qed

3. Introducing the variable $x = q^n$

Proposition 2.8 allows one to calculate the quantum $\mathfrak{sl}_n$-invariant of a link $L$ for each fixed $n \geq 2$. In this section, we introduce an algebra that allows us to unify the quantum $\mathfrak{sl}_n$ invariants of links into Laurent polynomials of a variable $x = q^n$.

3.1. Free associative algebra on $E_i, F_j$. Let
\[
\mathcal{X}_m = \{E_1, \ldots, E_{m-1}, F_1, \ldots, F_{m-1}\}
\]

and $\mathfrak{A}_m$ be the free associative $\mathbb{Q}(q)$-algebra generated by $\mathcal{X}_m$. For $i = 1, \ldots, m - 1$, define the divided powers by
\[
E_i^{(r)} := E_i^r / [r]! \in \mathfrak{A}_m, \quad F_i^{(r)} := F_i^r / [r]! \in \mathfrak{A}_m,
\]
where $[r]!$ is given by equation (15a). A $\mathbb{Q}(q)$-basis of $\mathfrak{A}_m$ can be described as follows. For $Y = (Y_1, \ldots, Y_r) \in (\mathcal{X}_m)^r$ and $k = (k_1, \ldots, k_r) \in \mathbb{N}^r$ define
\[
Y^{(k)} := Y_1^{(k_1)} Y_2^{(k_2)} \cdots Y_r^{(k_r)}.
\]

Then the set of all $Y^{(k)}$, where $Y_i \neq Y_{i+1}$ and $k_i \geq 1$, along with $k = \emptyset$, is a $\mathbb{Q}(q)$-basis of $\mathfrak{A}_m$.

Note that for each $a \in \mathbb{Z}^m$, $Y^{(k)} 1_a$ is a morphism in the category $n\mathbf{Lad}_m$. For $a, b \in \mathbb{Z}^m$ and $n > 1$, define the $\mathbb{Q}(q)$-linear map
\[
p^n_{a,b} : \mathfrak{A}_m \to \operatorname{Hom}_{n\mathbf{Lad}_m}(a, b), \quad p^n_{a,b}(Y^{(k)}) = 1_a Y^{(k)} 1_b.
\]

The algebra $\mathfrak{A}_m$ admits a natural $\mathbb{Z}^m$-grading, called weight, defined by
\[
w(F_i) = -\alpha_i, \quad w(E_i) = \alpha_i.
\]

Observe that $p^n_{a,b}(Y^{(k)}) = 0$ unless $a = b + w(Y^{(k)})$.

Let $I_k$ be the two-sided ideal of $\mathfrak{A}$ generated by $E_i^{(r)}, F_i^{(r)}$, with $i = 1, \ldots, m - 1$ and $r \geq k$. It is clear that $I_{k+1} \subset I_k$. Let $\hat{\mathfrak{A}}_m$ be the completion of $\mathfrak{A}_m$ with respect to the nested sequence of ideals $I_k$. Since $p^n_{a,b}(I_k) = 0$ if $k > n$, we can extend $p^n_{a,b}$ to a map, also denoted by $p^n_{a,b}$,
\[
p^n_{a,b} : \hat{\mathfrak{A}}_m \to \operatorname{Hom}_{n\mathbf{Lad}_m}(a, b).
\]
3.2. Convention on negative powers. The divided powers $E^{(r)}_i$ and $F^{(r)}_i$ are defined for non-negative integers $r$. It is convenient to extend them to negative powers by the following convention. For $r < 0$, $a \in \mathbb{Z}^m$, and $s \in \mathbb{Z}$ we use the following convention

$$E^{(r)}_i = F^{(r)}_i = 0 \quad \text{in } \tilde{A}_m$$

$$E^{(r)}_i 1_a = F^{(r)}_i 1_a = 0 \quad \text{in } \text{Lad}_m$$

With the above convention, Equations (14a), (14b), and (14d) can be rewritten in the following form: For all $r, s \in \mathbb{Z}$ and $i \neq j$, we have the following identities in $\text{Lad}_m$.

(22) \[ E^{(r)}_i F^{(s)}_i 1_a = \sum_{t \in \mathbb{R}} \left[ \langle a, \alpha_t \rangle + r - s \right] F^{(s-t)}_i E^{(r-t)}_i 1_a \]

(23) \[ E^{(r)}_i F^{(s)}_j 1_a = F^{(s)}_j E^{(r)}_i 1_a \]

(24) \[ E^{(s)}_i E^{(r)}_i 1_a = \left[ \frac{r + s}{r} \right] E^{(r+s)}_i 1_a, \quad F^{(s)}_i F^{(r)}_i 1_a = \left[ \frac{r + s}{r} \right] F^{(r+s)}_i 1_a. \]

3.3. Evaluation. Fix positive integers $n, m$. Recall that $\vartheta$ given by (16) is an object of $n\text{Lad}_{2m}$, and recall the evaluation map (18). This gives rise to an evaluation map

(25) \[ \text{ev}_n : \tilde{A}_{2m} \to \mathbb{Q}(q^{1/n}), \quad \text{ev}_n(x) := \text{ev}_{n,m}(p^n_{\vartheta, \vartheta}(x)). \]

Given a monomial $z$ in $E_i, F_j$ the element $\text{ev}_n(z)$ can be calculated by a simple algorithm moving each divided power in $E_i$ appearing in $z$ to the right using equations (22) and (23). Note that we are not moving divided powers of $E_i$ past divided powers of $E_j$. Since the $E_i$’s annihilate the weight $1_{\vartheta}$, all that remains after sliding all $E_i$’s to the right is a sum of products of the quantum binomials produced from the application of (22). For details see the example in Section 3.7 and Proposition 5.2.

Suppose $Y = (Y_1, \ldots, Y_k) \in (X_{2m})^k$ and $b = (b_1, \ldots, b_k) \in \mathbb{Z}^k$. There is an easy case when $\text{ev}_n(Y^{(b)}) = 0$, namely when $1_{\vartheta}Y^{(b)}1_{\vartheta}$ factors through a weight with a negative component. The weight of $Y^{(b)}$ is denoted by

$$w(Y^{(b)}) = (w_1(Y^{(b)}), \ldots, w_{2m}(Y^{(b)})) \in \mathbb{Z}^{2m}.$$  

We say $Y^{(b)}$ has negative weight if $w_j(Y^{(b)}) < 0$ for some $j$ with $m < j \leq 2m$. For an index $i, 1 \leq i \leq k$ define the $i$-th tail Tail$_i(Y, b)$ by

$$\text{Tail}_i(Y, b) = Y^{(b_i)}_i Y^{(b_{i+1})}_{i+1} \ldots Y^{(b_k)}_k.$$  

We say $(Y, b)$ is tail-negative if there is an index $i, 1 \leq i \leq k$, such that Tail$_i(Y, b)$ has negative weight.

**Lemma 3.1.** Suppose $(Y, b)$ is tail-negative. Then $\text{ev}_n(Y^{(b)}) = 0$ for all $n$.

**Proof.** Note that $Y^{(b)}1_{\vartheta}$ factors through Tail$_i(Y, b)1_{\vartheta} \in \text{Hom}_{\text{Lad}_{2m}}(\mu, \vartheta)$, where

$$\mu = w(\text{Tail}_i(Y, b)) + \vartheta.$$
Suppose \( w_j(\text{Tail}_i(Y, b)) < 0 \) for some \( j > m \) and \( 1 \leq i \leq k \). We have \( \mu_j = w(\text{Tail}_i(Y, b)) + \nu_j = w_j(\text{Tail}_i(Y, b)) < 0 \). By definition, \( \text{Tail}_i(Y, b)1_\emptyset = 0 \) in \( \text{Lad}_m^n \). Hence \( Y^{(i)}1_\emptyset = 0 \) in \( \text{Lad}_m^n \).

The tail-negative condition can be characterized by the following function

\[
(26) \quad \mathcal{H}(Y, b) := \prod_{j=m+1}^{2m} \prod_{i=1}^k \text{He}(w_j(\text{Tail}_i(Y, b))].
\]

where

\[
(27) \quad \text{He}(x) = \begin{cases} 
1 & \text{if } x \geq 0 \\
0 & \text{if } x < 0.
\end{cases}
\]

denotes the Heaviside function. Note that

\[
(28) \quad \mathcal{H}(Y, b) = \begin{cases} 
0 & \text{if } (Y, b) \text{ is tail-negative} \\
1 & \text{otherwise}.
\end{cases}
\]

3.4. **Braiding in \( \hat{A} \).** Suppose \( a = (a_1, \ldots, a_m) \in \mathbb{Z}^m \) and \( 0 \leq i \leq m - 1 \). Let

\[
(29a) \quad T_i(a) = (-1)^{a_i+a_{i+1}}q^{a_i} \sum_{s \in \mathbb{Z}} (-q)^{-s} E_i^{(s+a_{i+1}-a_i)} F_i^{(s)} \in \hat{A}
\]
\[
(29b) \quad T_i^{-1}(a) = (-1)^{a_i+a_{i+1}}q^{-a_i} \sum_{s \in \mathbb{Z}} (-q)^{s} E_i^{(s+a_{i+1}-a_i)} F_i^{(s)} \in \hat{A}
\]

Recall that we use the convention \( E_i^{(r)} = F_i^{(r)} = 0 \) if \( r < 0 \). Note that \( T_i^{-1}(a) \) is obtained from \( T_i(a) \) by the involution \( q \to q^{-1} \). From equation (19) and (20) it follows that for \( \varepsilon = \pm 1 \),

\[
(30) \quad \sigma_i^\varepsilon 1_a = q^{\varepsilon a_{i+1}} T_i^\varepsilon (a) 1_a \quad \text{in } n\text{Lad}_m.
\]

3.5. **Special functions.** Let \( Y = (Y_1, \ldots, Y_k) \in (\mathcal{X}_m)^k \). A function \( H : \mathbb{Z}^r \to \hat{A}_m \) is called a \( Y \)-special if

\[
(31) \quad H(a) = \sum_{s \in \mathbb{Z}} (-1)^{g_1(a, s)} q^{g_2(a, s)} Y^{(f(a, s))},
\]

where \( g_1, g_2 : \mathbb{Z}^{r+t} \to \mathbb{Z} \) are linear and \( f : \mathbb{Z}^{r+t} \to \mathbb{Z}^k \) is affine such that \( f(a, \cdot) : \mathbb{Z}^t \to \mathbb{Z}^k \) is injective for every \( a \in \mathbb{Z}^k \). The injectivity property ensures that the right hand side of (31) defines an element in \( \hat{A}_m \). The next lemma is easy to verify.

**Lemma 3.2.** (a) The function \( T_i, T_i^{-1} : \mathbb{Z}^m \to \hat{A}_m \) given by Equations (29a) and (29b) are \( (E_i, F_i) \)-special.

(b) Suppose \( f : \mathbb{Z}^k \to \mathbb{Z}^r \) is a linear function. Then the function \( H : \mathbb{Z}^k \to \hat{A}_m \) given by

\[
H(a) = Y^{(f(a))}
\]

is \( Y \)-special.

(c) If \( H' \) is \( Y' \)-special and \( H'' \) is \( Y'' \)-special, then \( H'H'' \) is \( Y' \cup Y'' \)-special.
Remark 3.3. A function \( g : \mathbb{Z}^s \to \mathbb{Z} \) is \textit{quadratic} if there is a \( s \times s \) matrix \( A \) with integer entries such that \( g(a) = a^T A a \). If \( g : \mathbb{Z}^s \to \mathbb{Z} \) is quadratic, then there is a linear \( f : \mathbb{Z}^s \to \mathbb{Z} \) such that \(-1)^g(a) = (-1)^f(a)\) for all \( a \in \mathbb{Z}^s \). Indeed, suppose \( g(a) = a^T A a \), where \( A \) is a \( s \times s \) matrix \( A \) with integer entries. Let \( B \) be the \( s \times s \) diagonal matrix defined by \( B_{ii} = A_{ii} \) and \( f(a) = Ba \). Then we have \((-1)^g = (-1)^f\).

3.6. Unifying the \( sl_n \)-link invariant. For \( a = (a_1, \ldots, a_r) \in \mathbb{Z}^r \) let \( \|a\|_\infty \) be the usual norm defined by \( \|a\|_\infty = \max_i |a_i| \).

Proposition 3.4. Suppose \( L \) is framed oriented link in the 3-space with \( r \) ordered components which is the closure of a braid with \( n \) strands. Then there is a \( Y \)-special function \( H : \mathbb{Z}^r \to \hat{\mathfrak{g}}_{2m} \) such that for all integers \( a_1, \ldots, a_r \in [0, n - 1] \), we have

\[
\hat{J}_L^\mathfrak{sl}_n(a_1, \ldots, a_r) = \text{ev}_n(H(a_1, \ldots, a_r)).
\]

Moreover, \((Y, f(a, s))\) is tail-negative whenever \( \|s\|_\infty > \|a\|_\infty \). Here \( f(a, s) \) is the function appearing in the presentation (31) of \( H \).

Proof. Let \( L \) be the closure of a braid \( \beta \in B_{2m} \) as in Figure 4, and \( a = (a_1, \ldots, a_r) \in \mathbb{N}^r \). Here \( \beta \) is a braid which is non-trivial only on the right \( m \) strands, and has a presentation

\[
\beta = \sigma_{i_1}^{\varepsilon_1} \cdots \sigma_{i_t}^{\varepsilon_t}, \quad i_j \in \{m + 1, \ldots, 2m - 1\} \text{ and } \varepsilon_j \in \{\pm 1\} \text{ for } j = 1, \ldots, t,
\]

where \( \sigma_i \) is the \( i \)-th standard generator of the braid group (see Figure 1).

Let \( \text{Lcl}(\beta, a) \), with labels coming from the labels \( a_i \) of \( L \), be the ladder closure of \( \beta \) as in Figure 5. Recall that the labelings \( b_i \) of the strands of \( \beta \) come from the labelings of \( L \), and \( c_i = n - b_i \). Let \( b = (b_1, \ldots, b_m) \) and \( c = (c_m, c_{m-1}, \ldots, c_1) \). Then each \( b_i \) is one of \((a_1, \ldots, a_r)\).

The horizontal lines at the bottom and the top of the braid \( \beta \) decomposes \( \text{Lcl}(\beta) \) into 3 morphisms in \( \text{Lad}^n_{2m} \):

\[
\text{Lcl}(\beta, a) = \text{Cap}_m(a) (\beta 1_{c \otimes b}) \text{Cup}_m(a).
\]

Each part can be written in a form that does not depend on \( n \).

Indeed, the lower morphism \( \text{Cup}_m(a) \) is a composition of \( F_i^{(b_j)} \) for various \( i, j \). Hence

\[
\text{Cup}_m(a) = \text{V}_m(a) 1_{\delta(n,m)},
\]

where \( \text{V}_m(a) \in \mathfrak{g}_{2m} \) is the product of several \( F_i^{(b_j)} \). Explicitly,

\[
\text{V}_m(a) = \prod_{k \in [1,m]} \left[ \left( \prod_{i \in [1,k-1]} \left( F_{m+k}^{(b_k)} F_{m-k}^{(b_k)} \right) \right) F_i^{(b_k)} \right],
\]

where

\[
\prod_{i \in [1,k]} x_i := x_1 x_2 \cdots x_k, \quad \prod_{i \in [1,k]} x_i := x_k x_{k-1} \cdots x_1.
\]

Then \( \text{V}_m(a) \), as a function of \( a \) is a special function, see Lemma 3.2.

Similarly, the top morphism

\[
\text{Cap}_m(a) = \Lambda_m(a) 1_{c \otimes b} = 1_{\delta(n,m)} \Lambda_m(a) 1_{c \otimes b}
\]
is a special function. Explicitly,
\[
\Lambda_m(a) = \prod_{k \in [1, m]} \left[ E_m^{(b_k)} \prod_{i \in [1, k-1]} \left( E_{m+k}^{(b_k)} E_{m-k}^{(b_k)} \right) \right].
\]

Now consider the middle morphism $\beta_{1_{\otimes b}}$. Using (33) and (30), we have
\[
\beta_{1_{\otimes b}} = z_1(a)z_2(a) \ldots z_l(a)1_{\otimes b},
\]
where
\[
z_j(a) = T_{ij}^{\sigma_j}(\sigma_{j+1} \ldots \sigma_{l}(c, b)).
\]
Using equation (29a) and (29b) for $T_{i}^{\pm 1}(b)$, we see that $z_j$ is a special function. Let
\[
H(a) = \Lambda_m(a)\tau(\beta(a)V_m(a)) = \Lambda_m(a)z_1(a)z_2(a) \ldots z_l(a)V_m(a).
\]
Then $H: \mathbb{Z}^k \to \hat{\mathbb{A}}_{2m}$, is a product of special functions, hence is a special function (see Lemma 3.2). By (30), we have
\[
\text{Lcl}(\beta, a) = q^\frac{1}{2} \sum_{i \in [m]} \ell_i |a_i| |a_j| 1_{\theta} H(a) 1_{\theta}.
\]
Applying the evaluation map $ev_n$ to both sides, using Proposition 2.8 and the normalization of $J_L$ for the left hand side, we obtain that
\[
J_L(e_{a_1}, \ldots, e_{a_k}) = ev_n(H(a)).
\]
This proves (32).

Let us have a closer look at the formula of $H$. By (29a) and (29b), $z_j$ has the form
\[
z_j = \sum_{s_j \in \mathbb{Z}} (-1)^g_j(a, s_j)q^{e_j}h_j(a, s_j)E_{f_j(a, s_j)} F_{i_j}^{(s_j)},
\]
where $g_j$ is a quadratic function, and $h_j, f_j$ are linear functions. From (34), it follows that $H$ has a presentation (31), where $s = (s_1, \ldots, s_l)$, and
\[
Y(f(a, s)) = \Lambda_m(a) \left( \prod_{j \in [1, l]} E_{i_j}^{(f_j(a, s_j))} F_{i_j}^{(s_j)} \right) V_m(a).
\]
Assume $\|s\|_\infty > \|a\|_\infty$, i.e. there is $l$ such that $|s_l| > \|a\|_\infty$. We can assume that $s_l > 0$, since other wise $s_l < 0$ and the factor $F_{i_l}^{(s_l)}$ on the right hand side of (35) is 0. We will show that the $(i_l + 1)$-th component of the weight of $F_{i_l}^{(s_l)}$ is negative, where
\[
z = \left( \prod_{j \in [l+1, t]} E_{i_j}^{(f_j(a, s_j))} F_{i_j}^{(s_j)} \right) V_m(a).
\]
This will prove that $(Y, f(a, s))$ is tail negative, since $i_l + 1 > m$. Note that
\[
w(z) = w(z_{l+1}(a) \ldots z_l(a) V_m(a)) = (c_1 - n, \ldots, c_m - n, b'),
\]
where $b'$ is a permutation of $b$. Since $\|b'\|_\infty = \|b\|_\infty = \|a\|_\infty$, we have
\[
w_{i_l+1}(F_{i_l}^{(s_l)} z) = -s_l + (b')_{i_l+1} < 0,
\]
which completes the proof of the proposition.  \qed

Remark 3.5. Our evaluation algorithm should be closely related to the variant of skew Howe duality defined for so-called doubled Schur algebras in [QSb, QSa].
3.7. **An example: the trefoil knot.** Before we proceed further, let us illustrate Proposition 3.4 by computing the invariant of the trefoil, and draw some useful conclusions regarding $q$-holonomicity of the invariant.

We take

\[(36) \quad \beta = \sigma_1^3 = \sigma_1 \sigma_1 \sigma_1, \quad m = 2, \quad \vartheta = (n, n, 0, 0).\]

The link $L = \text{cl}(\beta)$ is the right-handed trefoil knot, colored by one $a \in \mathbb{N} \cap [0, n-1]$, and $b = (a, a)$ (see Figure 6).

![Figure 6. The ladder closure of braid $\beta = \sigma_1^3$.](image)

By Proposition 3.4, and equation (34) we obtain that $\tilde{J}_{31}^{sl_n}(e_a) = \text{ev}_n(H(a))$, where

\[(37) \quad H(a) = q^{3a} E_2^{(a)} E_1^{(a)} E_3^{(a)} E_2^{(a)} (T_3(b))^3 F_2^{(a)} F_3^{(a)} F_1^{(a)} F_2^{(a)}.\]

Using Equation (29a), we replace each occurrence of $T_3(b)$ by a sum over the integers, and obtain the following triple sum formula

\[(38) \quad q^{-3a} H(a) = \sum_{s_1, s_2, s_3 \in \mathbb{Z}} (-q)^{s_1+s_2+s_3} E_2^{(a)} E_1^{(a)} E_3^{(a)} E_2^{(a)} (E_3^{(s_1)} E_2^{(s_2)} E_3^{(s_3)}) F_2^{(a)} F_3^{(a)} F_1^{(a)} F_2^{(a)}.\]

This is an explicit form of special function for $H$.

Next, we use the commutation rules given in equations (22)–(24) to sort the expression of $H(a) \vartheta$, moving all the $E$’s to the right and all the $F$’s to the left. Every time we move $E_i^{(r)}$ (from the left) past an $F_j^{(s)}$ (from the right), we obtain a 1-dimensional sum over the integers. Then, use equation (17a) to add some delta functions in the sum. Finally, Equ. (53), which is explained later in the proof of Proposition 5.2, tells us to add Heaviside functions $\text{He}(k)$ (see Section 4). Doing so, we eventually get the following formula for the quantum $\mathfrak{sl}_n$-invariant of the trefoil colored by $e_a$ (the details are given in the appendix).
\[ \tilde{J}^{4\lambda_t}_L (e_a) = q^{na} \sum_{s \in \mathbb{Z}^6} \sum_{\tau \in \mathbb{Z}} \frac{(-q)^{s_1 + s_2 + s_3} \text{He}(a - s_1) \text{He}(a - s_2) \text{He}(a - s_3) \text{He}(a + s_1 + s_2 - s_4) \text{He}(a + s_2 + s_3 - s_5) \text{He}(\tau) \text{He}(a - \tau) \sum_{s_i \in \mathbb{Z}} (-q)^{s_i}}{s_2 + s_3 + \tau} \left[ \begin{array}{c} s_2 + s_3 + \tau \\ s_2 + s_3 - s_5 \end{array} \right] \left[ \begin{array}{c} s_1 + s_2 - s_4 \\ s_2 + s_3 - s_5 \end{array} \right] \left[ \begin{array}{c} s_2 + s_3 + \tau \\ s_2 + s_3 - s_5 \end{array} \right] \left[ \begin{array}{c} s_1 + s_2 - s_4 \\ s_2 + s_3 - s_5 \end{array} \right] \left[ \begin{array}{c} \tau \\ s_2 + s_3 - s_5 \end{array} \right] \left[ \begin{array}{c} \tau \\ s_2 + s_3 - s_5 \end{array} \right] \left[ \begin{array}{c} \tau \\ s_2 + s_3 - s_5 \end{array} \right] \right] \]

where \( \tau = s_1 + s_2 + s_3 - s_4 - s_5 - s_6 \) and \( s = (s_1, \ldots, s_6) \in \mathbb{Z}^6 \). Keep in mind the convention that \( \left[ \begin{array}{c} \tau \\ s \end{array} \right] = 0 \) if \( s < 0 \).

Let us end this example with some observation. The above formula has the form

\[ \tilde{J}^{4\lambda_t}_L (e_a) = \sum_{s \in \mathbb{Z}^6} F(a, s), \]

where \( F(a, s) \) is a finite product of factors of the following shape

(i) \( (\pm q)^{A(a,s)}, \)
(ii) \( \text{He}(A(a,s)), \)
(iii) quantum binomial \( \left[ \begin{array}{c} A(a,s) \\ B(a,s) \end{array} \right] \)
(iv) quantum binomial \( \left[ \begin{array}{c} n + A(a,s) \\ B(a,s) \end{array} \right] = \left[ \begin{array}{c} q^n A(a,s) \\ B(a,s) \end{array} \right] \), where for \( s, l \in \mathbb{Z} \) we define

\[ \left[ \begin{array}{c} x; s \\ l \end{array} \right] = \begin{cases} 0 & \text{if } l < 0 \\ \prod_{j=1}^l x^{q^j - j + 1} - x^{-1} q^{-s+j-1} & \text{if } l \geq 0. \end{cases} \]

Here \( A(a,s) \) and \( B(a,s) \) are \( \mathbb{Z} \)-linear functions. Moreover, for each integer value of \( a \) and \( n \), the sum on the right hand side of (40) is terminating in the sense that only a finite number of terms are non-zero. The number of terms are bounded by a polynomial function of \( a \).

We will show that a similar formula exists for any framed oriented link colored with \( e_a \). But before we do so, let us recall what is a \( q \)-holonomic function.

4. \( q \)-Holonomic Functions

\( q \)-holonomic functions of one variable were introduced by the seminal paper of Zeilberger [Zei90]. The class of \( q \)-holonomic functions resembles in several ways and the class of holonomic \( D \)-modules, as is acknowledged by conversations of Zeilberger and Bernstein prior to the introduction of holonomic functions, [Zei90]. An extension of the definition to \( q \)-holonomic functions with several variables was given by Sabbah [Sab93] using the language of homological algebra. In this section we will review the definition of \( q \)-holonomic functions of several variables, give examples, and list the closure properties of this class under some operations. Our exposition follows Zeilberger and Sabbah, and the survey paper of two of the authors [GL].

We should point out, however, that the precise definition of \( q \)-holonomic functions is not used in the proof of Theorem 1.1. If the reader wishes to take as a black box the examples of \( q \)-holonomic functions given below, and their closure properties, then they can skip this section altogether and still deduce the proof of Theorem 1.1.

4.1. The Quantum Weyl Algebra. Let \( V \) denote a fixed (not necessarily finitely generated) \( \mathcal{A} \)-module, where \( \mathcal{A} = \mathbb{Z}[q^{\pm 1}] \). For a natural number \( r \), let \( S_r(V) \) be the set of all functions
The filtration \( f : \mathbb{Z}^r \to V \) and \( S_r(V) \) the set of functions \( f : \mathbb{N}^r \to V \). For \( i = 1, \ldots, r \) consider the operators \( L_i \) and \( M_i \) which act on functions \( f \in S_r(V) \) by

\[
(L_i f)(n_1, \ldots, n_i, \ldots, n_r) = f(n_1, \ldots, n_i + 1, \ldots, n_r) \tag{42}
\]

\[
(M_i f)(n_1, \ldots, n_r) = q^{n_i} f(n_1, \ldots, n_r). \tag{43}
\]

It is clear that \( L_i, M_j \) are invertible operators that satisfy the \( q \)-commutation relations

\[
M_i M_j = M_j M_i \tag{44a}
\]

\[
L_i L_j = L_j L_i \tag{44b}
\]

\[
L_i M_j = q^{\delta_{i,j}} M_j L_i \tag{44c}
\]

for all \( i, j = 1, \ldots, r \).

**Definition 4.1.** The \( r \)-dimensional quantum Weyl algebra \( \mathbb{W}_r \) is the \( \mathcal{A} \)-algebra generated by \( L_1^{\pm 1}, \ldots, L_r^{\pm 1}, M_1^{\pm 1}, \ldots, M_r^{\pm 1} \) subject to the relations (44a)–(44c). Let \( \mathbb{W}_{r,+} \) be the subalgebra of \( \mathbb{W}_r \) generated by the non-negative powers of \( M_j, L_j \).

Given \( f \in S_r(V) \), the annihilator \( \text{Ann}(f) \) (a left \( \mathbb{W}_r \) module) is defined by

\[
\text{Ann}(f) = \{ P \in \mathbb{W}_r \mid P f = 0 \} \tag{45}
\]

This gives rise to a cyclic \( \mathbb{W}_r \)-module \( M_f \), defined by \( M_f = \mathbb{W}_r f \subset S_r(V) \), and isomorphic to \( \mathbb{W}_r / \text{Ann}(f) \).

### 4.2. Definition of \( q \)-holonomic functions.

In this section we follow closely the work of Sabbah [Sab93]. Let \( N \) be a finitely-generated \( \mathbb{W}_{r,+} \)-module. Consider the increasing filtration \( \mathcal{F} \) on \( \mathcal{T}_{r,+} \) given

\[
\mathcal{F}_n \mathcal{T}_{r,+} = \{ \mathcal{A} \text{-span of all monomials } M^\alpha L^\beta \text{ with } \alpha, \beta \in \mathbb{N}^r \text{ with total degree } \leq n \}. \tag{46}
\]

The filtration \( \mathcal{F} \) on \( \mathbb{W}_{r,+} \) induces an increasing filtration on \( N \), defined by \( \mathcal{F}_n N = \mathcal{F}_n \mathbb{W}_{r,+} N \). Note that \( \mathcal{F}_n \mathbb{W}_{r,+} \), and consequently \( \mathcal{F}_n N \), are finitely-generated \( \mathcal{A} \)-modules for all natural numbers \( n \). An analog of Hilbert’s theorem for this non-commutative setting holds: the dimension of the \( \mathbb{Q}(q) \)-vector space \( \mathbb{Q}(q) \otimes_{\mathcal{A}} \mathcal{F}_n N \) is a polynomial in \( n \), for big enough \( n \). The degree of this polynomial is called the dimension of \( N \), and is denoted by \( d(N) \).

In [Sab93, Theorem 1.5.3] Sabbah proved that \( d(N) = 2r - \text{codim}(N) \), where

\[
\text{codim}(N) = \min \{ j \in \mathbb{N} \mid \text{Ext}_{\mathbb{W}_{r,+}}^j(N, \mathbb{W}_{r,+}) \neq 0 \}.
\]

Sabbah also proved that \( d(N) \geq r \) if \( N \) is a non-zero and does not have monomial torsion. Here a monomial torsion is a monomial \( P \) in \( \mathbb{W}_{r,+} \) such that \( Px = 0 \) for a certain non-zero \( x \in N \). It is easy to see that \( N \) embeds in the \( \mathbb{W}_r \)-module \( \mathbb{W}_r \otimes_{\mathbb{W}_{r,+}} N \) if and only if \( N \) has no monomial torsion. Throughout the paper, we will assume that all \( \mathbb{W}_{r,+} \)-modules do not have monomial torsion.

**Definition 4.2.** (a) A \( \mathbb{W}_{r,+} \)-module \( N \) is \( q \)-holonomic if \( N = 0 \) or \( N \) is finitely-generated, does not have monomial torsion, and \( d(N) = r \).

(b) An element \( f \in N \), where \( N \) is a \( \mathbb{W}_{r,+} \)-module, is \( q \)-holonomic over \( \mathbb{W}_{r,+} \) if \( \mathbb{W}_{r,+} f \) is a \( q \)-holonomic \( \mathbb{W}_{r,+} \)-module.
The above definition defines $q$-holonomic $\mathbb{W}_{r,+}$ modules, and our next task is to define $q$-holonomic $\mathbb{W}_r$ modules. Let $M$ be a non-zero finitely-generated left $\mathcal{T}_r$-module. Following [Sab93, Section 2.1], the codimension and dimension of $M$ are defined in terms of homological algebra by

$$\text{codim}(M) = \min\{j \in \mathbb{N} \mid \text{Ext}^j_{\mathbb{W}_r}(M, \mathcal{T}_r) \neq 0\}, \quad \dim(M) = 2r - \text{codim}(M).$$

The key Bernstein inequality (proved by Sabbah [Sab93, Thm.2.1.1] in the $q$-case) asserts that if $M \neq 0$ is a finitely generated $\mathbb{W}_r$-module, then $\dim(M) \geq r$.

**Definition 4.3.** (a) A $\mathbb{W}_r$-module $M$ is $q$-holonomic if either $M = 0$ or $M$ is finitely-generated and $\dim(M) = r$.

(b) An element $f \in M$, where $M$ is a $\mathbb{W}_r$-module, is $q$-holonomic over $\mathbb{W}_r$ if $\mathbb{W}_r \cdot f$ is a $q$-holonomic $\mathbb{W}_r$-module.

Next we compare $q$-holonomic modules over $\mathbb{W}_r$ versus over $\mathbb{W}_{r,+}$. The following proposition was proven in [GL, Sec.3]. Next we compare $q$-holonomic modules over $\mathbb{W}_r$ versus over $\mathbb{W}_{r,+}$ using Sabbah [Sab93, Cor.2.1.4].

**Proposition 4.4.** Suppose $f \in M$, where $M$ is a $\mathbb{W}_r$-module. Then $f$ is $q$-holonomic over $\mathbb{W}_r$ if and only if it is $q$-holonomic over $\mathbb{W}_{r,+}$.

The next corollary is taken from [GL, Sec.3].

**Corollary 4.5.** If $f \in S_r(V)$ is $q$-holonomic and $g \in S_{r,+}(V)$ is its restriction to $\mathbb{N}^r$, then $g$ is $q$-holonomic.

**Remark 4.6.** The definition of $q$-holonomic $\mathcal{A}$-modules can be extended to $q$-holonomic $\mathcal{R}$-modules where $\mathcal{R}$ is the ring (and also an $\mathcal{A}$-module)

$$\mathcal{R} = Q(q)[x^{\pm 1}].$$

Proposition 4.4 and Theorems 4.7 and 4.8 below hold after replacing $\mathcal{A}$ by $\mathcal{R}$.

4.3. Properties of $q$-holonomic functions. In this section we summarize some closure properties of $q$-holonomic functions, whose proofs can be found in [GL, Sec.5].

**Theorem 4.7.** Suppose $f, g \in S_r(V)$ are $q$-holonomic functions. Then,

(a) $f + g$ is $q$-holonomic.

(b) $fg$ is $q$-holonomic.

(c) Restriction. For a fixed $a \in \mathbb{Z}$, the function $g \in S_{r-1}(V)$ defined by

$$g(n_1, \ldots, n_{r-1}) = f(n_1, \ldots, n_{r-1}, a)$$

is $q$-holonomic.

(d) Extension. The function $h \in S_{r+1}(V)$ defined by

$$h(n_1, \ldots, n_{r+1}) = f(n_1, \ldots, n_r)$$

is $q$-holonomic.

(e) Linear substitution. If $A \in \text{GL}(r, \mathbb{Z})$ and $f \in S_r(V)$ is $q$-holonomic, so is the composition $A \circ f \in S_r(V)$. 
Let $S_{r-1,1}(V)$ denote set of all functions $f : \mathbb{Z}^r \to V$ such that for every $(n_1, \ldots, n_{r-1}) \in \mathbb{Z}^{r-1}$, $f(n_1, \ldots, n_r) = 0$ for all but a finite number of $n_r$.

**Theorem 4.8.** (a) Suppose $f \in S_{r-1,1}(V)$ is $q$-holonomic. Then, $g \in S_{r-1}(V)$, defined by

$$g(n_1, \ldots, n_r) = \sum_{n_r \in \mathbb{Z}} f(n_1, \ldots, n_r),$$

is $q$-holonomic.

(b) Suppose $f \in S_r(V)$ is $q$-holonomic. Then $h \in S_{r+1}(V)$ defined by

$$h(n_1, \ldots, n_{r-1}, a, b) = \sum_{n_r = a}^{b} f(n_1, n_2, \ldots, n_r)$$

is $q$-holonomic.

### 4.4. Elementary $q$-holonomic functions.

A function $g : \mathbb{Z}^s \to \mathbb{Z}^r$ is *affine* if there is an $r \times s$ matrix $A$ with integer entries and $b \in \mathbb{Z}^r$ such that $g(a) = Aa + b$. If $b = 0$, such a function is called *linear*.

A function $f : \mathbb{Z}^r \to \mathbb{Q}(q)[x^{\pm 1}]$ is called an *elementary block* if $f$ is a finite product of a composition of a linear function $\mathbb{Z}^r \to \mathbb{Z}^s$ (for $s = 1, 2$) with one of one of the following functions:

(i) $\mathbb{Z} \to \mathbb{Z}[q^{\pm 1}]$, $k \to (-1)^k$, or $k \to q^k$, or $k \to \text{He}(k)$,

(ii) $\mathbb{Z}^2 \to \mathbb{Z}[q^{\pm 1}]$, $(k, l) \to \delta_{k,l}$, or $(k, l) \to \begin{bmatrix} k \\ l \end{bmatrix}$, or $(k, l) \to \begin{bmatrix} x; k \\ l \end{bmatrix}$.

Observe that functions of the form (i) or (ii) above are $q$-holonomic [GL].

A function $f : \mathbb{Z}^r \to \mathbb{Q}(q)[x^{\pm 1}]$ is called *elementary* if can be presented by a terminating sum

$$f(a) = \sum_{b \in \mathbb{Z}^l} g(a, b),$$

where $g : \mathbb{Z}^{k+l} \to \mathbb{Q}(q)[x^{\pm 1}]$ is an elementary block. Here the sum is terminating means for each $a$ there are only a finite number of $b$ such that $g(a, b) \neq 0$. Theorems 4.7 and 4.8 imply the following.

**Corollary 4.9.** Every elementary block and every elementary function is $q$-holonomic.

### 5. Proof of Theorem 1.1

#### 5.1. Evaluation of monomials is $q$-holonomic.

For $n \in \mathbb{Z}$ let $\text{eval}_n : \mathbb{Q}(q)[x^{\pm 1}] \to \mathbb{Q}(q)$ be the $\mathbb{Q}(q)$-algebra homomorphism defined by

$$\text{eval}_n(f) = f|_{x=q^n}.\quad(49)$$

The next lemma recovers an element of $\mathbb{Q}(q)[x^{\pm 1}]$ from its evaluations.

**Lemma 5.1.** Suppose that $f, g \in \mathbb{Q}(q)[x^{\pm 1}]$ satisfy $\text{eval}_n(f) = \text{eval}_n(g)$ for infinitely many $n$. Then $f = g$.

**Proof.** This follows from the fact that a Laurent polynomial in $x$ has at most $k$ roots, where $k$ is the difference between the highest order and the lowest order in $x$. \qed
Let $X = (X_1, \ldots, X_k)$ be a sequence of elements of the set $X_{2m}$ from equation (21). Recall that for $b = (b_1, \ldots, b_k) \in \mathbb{Z}^k$, the monomial $X(b) \in A_{2m}$ and its weight are defined in Section 3.1. By convention, $X(b) = 0$ if one of $b_i$ is negative. The goal of this subsection is to calculate

$$ev_n(X(b)) = ev(1_{\vartheta}X(b)1_{\vartheta})$$

where $\vartheta = (n^m, 0^m) \in \mathbb{Z}^{2m}$.

**Proposition 5.2.** Suppose $X = (X_1, \ldots, X_k)$ is a sequence of elements of the set $X_{2m}$. There exists a unique function

$$Q_X : \mathbb{Z}^k \rightarrow Q(q)[x^{\pm 1}]$$

such that for all $b \in \mathbb{Z}^k$,

$$ev_n(X(b)) = \text{eval}_n(Q_X(b)).$$

Moreover, $Q_X$ is an elementary function given by

$$Q_X(b) = \sum_{j \in \mathbb{Z}^l} F_X(b, j)$$

for certain $l \in \mathbb{N}$ and elementary block $F_X : \mathbb{Z}^{k+l} \rightarrow Q(q)[x^{\pm 1}]$. In addition,

(i) $F_X(b, j) = 0$ if $\|j\|_{\infty} > \|b\|_{\infty}$ (which implies the sum (51) is terminating), and

(ii) $F_X(b, j) = 0$ if $(X, b)$ is tail-negative if one of the component of $b$ is negative.

**Proof.** The uniqueness follows from Lemma 5.1. Let us prove the existence.

The idea is to move the $E_i$ to the right of $F_j$ using Equations (22) and (23) (this creates a sum of a product of $q$-binomials) and then use Equation (17a), which creates a product of $\delta$-functions. Besides, we insert Heaviside functions to make the sum terminating. The result is an elementary function. Now we give the details of the proof.

Let $l \leq k$ be the maximal index such that $X_l \in \{E_1, \ldots, E_{2m-1}\}$. We use induction on $k$, then induction on $l$. If $k = 0$ the statement is obvious.

For fixed $k$, we use induction on $l$, beginning with $l = k$ and going down.

(a) Suppose $l = k$. Recall that $\vartheta = (n^m, 0^m)$. Using (17a), we have

$$X(b)1_{\vartheta} = \delta_{b_k, 0}Y(b)1_{\vartheta},$$

where $Y = (X_1, \ldots, X_{k-1})$ and $b' = (b_1, \ldots, b_{k-1})$. For $Y$ the statement holds. Define

$$F_X(b, j) := F_Y(b', j)\delta_{b_k, 0}, \quad Q_X(b) = \sum_{j \in \mathbb{Z}^l} F_X(b, j)$$

Then $F_X(b, j)$ is an elementary summand. Both statements (i) and (ii) for $F_X(b, j)$ follow immediately from those for $F_Y(b', j)$. Then $Q_X$ is an elementary $q$-holonomic function, and (50) holds.

(b) Suppose $l < k$. Assume that $X_l = E_r$ and $X_{l+1} = F_s$. Let $Y = (Y_1, \ldots, Y_k)$ be the sequence defined by $Y_i = X_i$ for all $i$ except $Y_l = X_{l+1}$ and $Y_{l+1} = X_l$. By induction, the statement holds for $Y$, and we can define elementary summand $F_Y(b, j)$ for $(b, j) \in \mathbb{Z}^{k+l}$. Consider two cases.

Case 1: $r \neq s$. Because $E_rF_s = F_sE_r$, we have $X(b) = Y(b')$ where $b'$ is obtained from $b$ by swapping the $l$-th and $(l+1)$-components. This case is reduced to the case of $Y$ by defining $F_X(b, j) = F_Y(b', j)$.
Case 2: $r = s$. We have

$$X^{(b)} = X_{\text{left}} \left( E_{r}^{(b_{r})} F_{r}^{(b_{r+1})} \right) X_{\text{right}}$$

where

$$X_{\text{left}} = \prod_{j \in [1,l-1]} X_{j}^{(b_{j})}, \quad X_{\text{right}} = \prod_{j \in [l+2,k]} X_{j}^{(b_{j})}.$$ 

We have $X_{\text{right}} 1_{\vartheta} \in \text{Hom}_{\text{Lad}_{2m}}(\mu, \vartheta)$, where

$$\mu = \vartheta + w(X_{\text{right}}) = \vartheta - \sum_{j=l+2}^{k} b_{j} \alpha_{j}.$$ 

Here the index $i_{j}$ is defined so that $X_{j} = F_{b_{j}}$ for $j > l$. Using (14a), we have

$$X^{(b)} 1_{\vartheta} = \sum_{t \in \mathbb{Z}} \left[ \langle \mu, \alpha_{r} \rangle + b_{l} - b_{l+1} \right] X_{\text{left}} F_{r}^{(b_{r+1} - t)} E_{r}^{(b_{r} - t)} X_{\text{right}} 1_{\vartheta}$$

$$= \sum_{t \in \mathbb{Z}} \left[ \langle \mu, \alpha_{r} \rangle + b_{l} - b_{l+1} \right] Y^{(b')} 1_{\vartheta},$$

where $b' = (b'_{1}, \ldots, b'_{l})$ such that $b'_{i} = a_{i}$ for all $i$ except for $i = l, l+1$, with $b'_{l} = b_{l+1} - t, b'_{l+1} = b_{l} - t$. Clearly $b'$ is a linear function of $(b, t)$.

Note that $\langle \vartheta, \alpha_{r} \rangle = n \delta(r, m)$. From the definition of $\mu$,

$$\langle \mu, \alpha_{r} \rangle + b_{l} - b_{l+1} = n \delta(r, m) + \text{Lin}(b)$$

where $\text{Lin}(b) = \langle w(X_{\text{right}}), \alpha_{r} \rangle + b_{l} - b_{l+1}$ is a $\mathbb{Z}$-linear form of $b$. For $j \in \mathbb{Z}^{l+1}$ we write $j = (j', t)$, i.e. $t$ is the last component of $j$. For $b \in \mathbb{Z}^{k}$ and $j \in \mathbb{Z}^{l+1}$, define

$$F_{X}(b, j) = \begin{cases} \left[ \begin{array}{c} x; \text{Lin}(b) \vspace{1em} \\ t \end{array} \right] F_{Y}(b', j') \mathcal{H}(X, b) & \text{if } r = m \\ \text{Lin}(b) \vspace{1em} \\ t \end{cases}$$

(53)

where $\mathcal{H}(X, b)$, defined by (26), is an elementary function of $b$.

Then $F_{X}(b, j)$ is an elementary function. Let us prove (i) and (ii), which claim $F_{X}(b, j) = 0$ under certain conditions. If $t < 0$, then the first factor on the right hand sides of (53) is 0. Hence we will assume $t \geq 0$ in what follows.

(i) Suppose $\|j\|_{\infty} > \|b\|_{\infty}$. Then either $\|j'\|_{\infty} > \|b\|_{\infty}$ or $|t| > \|b\|_{\infty}$. In the first case, $\|j'\|_{\infty} > \|b\|_{\infty} \geq \|b'\|_{\infty}$, and $F_{Y}(b', j') = 0$. In the latter case, the $l$-th component of $b'$ is negative. By (ii) we have $F_{Y}(b', j') = 0$. Hence $F_{X}(b, j) = 0$.

(ii) First assume that one of the component of $b$ is negative. Then one of the component of $b'$ is negative. Hence $F_{Y}(b', j') = 0$, implying $F_{X}(b, j) = 0$.

Now assume that $(X, b)$ is tail-negative. Then the third factor in the right hand sides of (53) is 0. Hence $F_{X}(b, j) = 0$.

Let us prove (50). If $(X, b)$ is tail-negative, then both sides of (50) are 0, by Lemma 3.1 and the property of $\mathcal{H}(X, b)$. Assume now $(X, b)$ is not tail-negative. Then $\mathcal{H}(X, b) = 1$, and (50) follows from (52), (53), and the identity (50) applicable to $Y$. 

THE COLORED HOMFLYPT FUNCTION IS q-HOLONOMIC 29
This completes the proof of the proposition. \qed

5.2. Coloring with partitions with one column.

**Theorem 5.3.** Suppose $L$ is an oriented, framed link with $r$ ordered components. There exists a unique function 
\[ Q_L : \mathbb{N}^r \to \mathbb{Q}(q)[x^{\pm 1}] \]
such that for any integer $n \geq 2$ and $a = (a_1, \ldots, a_r) \in \mathbb{N}^r \cap [0, n-1]^r$,
\[ \bar{J}^n_L(e_{a_1}, \ldots, e_{a_r}) = \text{eval}_n(Q_L(a)). \tag{54} \]
Moreover, $Q_L$ is elementary, hence a $q$-holonomic function.

**Proof.** The uniqueness follows from Lemma 5.1. Let us prove the existence. Suppose $L$ is the closure of a braid $\beta$ on $m$ strands, as in Section 3.5. By Proposition 3.4, there exists a sequence $X = (X_1, \ldots, X_k)$ of elements from $E_i, F_i$ with $i = 1, \ldots, 2m-1$ and linear functions $g_1, g_2 : \mathbb{Z}^{r+t} \to \mathbb{Z}$ and $f : \mathbb{Z}^{r+t} \to \mathbb{Z}^k$ such that 
\[ \bar{J}^n_L(e_{a_1}, \ldots, e_{a_r}) = \sum_{s \in \mathbb{Z}^t} (-1)^{g_1(a,s)} q^{g_2(a,s)} \text{eval}_n \left(X(f(a,s))\right). \]

By Proposition (5.2), there exists elementary summand function $F_X : \mathbb{Z}^{k+l} \to \mathbb{Q}(q)[x^{\pm 1}]$ such that 
\[ \bar{J}^n_L(e_{a_1}, \ldots, e_{a_r}) = \sum_{s \in \mathbb{Z}^t} (-1)^{g_1(a,s)} q^{g_2(a,s)} \text{eval}_n \left( \sum_{j \in \mathbb{Z}^l} F_X(f(a,s), j) \right). \]

By (i) of Proposition 5.2,
\[ F_X(f(a,s), j) = 0 \quad \text{if} \quad \|j\|_\infty > \|f(a,s)\|_\infty. \tag{55} \]

When $\|s\|_\infty > \|a\|_\infty$, $(X, f(a,s))$ is tail-negative, see Proposition 3.4. Hence, by (ii) of Proposition 5.2,
\[ F_X(f(a,s), j) = 0 \quad \text{if} \quad \|s\|_\infty > \|a\|_\infty. \tag{56} \]

Equations (55) and (56) imply that the sum 
\[ Q_L(a) := \sum_{s \in \mathbb{Z}^t} \sum_{j \in \mathbb{Z}^r} (-1)^{g_1(a,s)} q^{g_2(a,s)} F_X(f(a,s), j) \]
is terminating for each $a \in \mathbb{Z}^k$.

Then $Q_L$ is elementary $q$-holonomic, and equation (54) holds. \qed

**Remark 5.4.** By our construction, $Q_L$ vanishes in $\mathbb{Z}^r \setminus \mathbb{N}^r$.

**Remark 5.5.** Theorem 5.3 gives an alternative construction of the colored HOMFLYPT polynomial $W_L$ of a framed, oriented link colored by partitions with one column. By the uniqueness,
\[ Q_L(a_1, \ldots, a_r) = W_L(e_{a_1}, \ldots, e_{a_r}). \]
5.3. The Jacobi-Trudi formula. In this section we explain how to extend the \( q \)-holonomicity of the HOMFLYPT polynomial of a link colored by partitions with one row to the case of partitions with a fixed number of rows. The key idea is the Jacobi-Trudi formula which expresses the Schur function \( s_\lambda \) of a partition \( \lambda \in \mathcal{P}_\ell \), considered as an element of the algebra \( \Lambda \), as a determinant of a matrix whose entries are partitions with one row. Observe that for partitions with one row (resp. one column) we have \( s_\lambda = h_\lambda \) (resp., \( s_\lambda = e_\lambda \)).

The Jacobi-Trudi formula \cite{Mac95} states that if \( \lambda = (\lambda_1, \ldots, \lambda_\ell) \in \mathcal{P}_\ell \), then in \( \Lambda \),

\[
s_\lambda = \det \left( (e_{\lambda_i+j-1})_{i,j=1}^{\ell} \right)
\]

where the right hand side is an \( \ell \times \ell \) determinant, with the convention \( e_0 = 1 \) and \( e_n = 0 \) for \( n < 0 \). For example, if \( \lambda \) is a partition with three rows with \( \lambda_1, \lambda_2 \) and \( \lambda_3 \) boxes, then we have

\[
s_{\lambda_1,\lambda_2,\lambda_3} = -e_{\lambda_1+2}e_{\lambda_2}e_{\lambda_3-2} + e_{\lambda_1+1}e_{\lambda_2+1}e_{\lambda_3-2} + e_{\lambda_1+2}e_{\lambda_2-1}e_{\lambda_3-1} - e_{\lambda_1}e_{\lambda_2+1}e_{\lambda_3-1} - e_{\lambda_1+1}e_{\lambda_2-1}e_{\lambda_3} + h_{\lambda_1}e_{\lambda_2}e_{\lambda_3}.
\]

Let \( L \) denote a framed, oriented link \( L \) with \( r \) ordered components, and choose a partition \( \lambda \in \mathcal{P}_\ell \), and partitions \( \mu_2, \ldots, \mu_r \). Then, part (c) of Proposition 2.4 implies that

\[
W_{L}(\lambda, \mu_1, \ldots, \mu_r) = \sum_{\sigma \in \text{Sym}_r} \text{sgn}(\sigma)W_{L'}(e_{\lambda_{1}+\sigma(1)-1}, \ldots, e_{\lambda_\ell+\sigma(\ell)-\ell}, \mu_1, \ldots, \mu_r).
\]

where \( L' \) is the link obtain from \( L \) by replacing the first framed component of \( L \) by \( \ell \) of its parallels.

5.4. Proof of Theorem 1.1. Fix a framed oriented link \( L \) with \( r \) ordered components. Using the symmetry of the HOMFLYPT polynomial from part (c) of Proposition 2.4, it suffices to show that the colored HOMFLYPT polynomial of \( L \), colored by partitions with at most \( \ell \) rows, is \( q \)-holonomic. Said differently, it suffices to show that the function \( W_L \circ (t_\ell^r)^r : \mathbb{N}^{r\ell} \to \mathbb{Q}(q)[x^{\pm 1}] \) is \( q \)-holonomic. Let \( \lambda = (\lambda_1, \ldots, \lambda_{r\ell}) \in \mathbb{N}^{r\ell} \). Using Equation (57), we have

\[
(W_L \circ (t_\ell^r)^r)(\lambda) = \sum_{\sigma} \text{sgn}(\sigma)W_{\Delta L}(e_{f_{\sigma,1}(\lambda)}, \ldots, e_{f_{\sigma,r\ell}(\lambda)})
\]

where the sum is over \( \sigma = (\sigma_1, \ldots, \sigma_r) \in (\text{Sym}_r)^r \), \( \text{sgn}(\sigma) = \text{sgn}(\sigma_1) \ldots \text{sgn}(\sigma_r) \) and \( \Delta L \) is the link with \( r\ell \) components obtained from \( L \) by replacing each component with its \( \ell \)-th parallel and \( f_{\sigma,i} : \mathbb{Z}^{r\ell} \to \mathbb{Z} \) are affine. Parts (a) and (e) of Theorem 4.7 together with Theorem 5.3 imply that \( W_L \circ (t_\ell^r)^r \) is a sum of \( q \)-holonomic functions, thus is \( q \)-holonomic. This concludes the proof of Theorem 1.1. \( \square \)

APPENDIX A. THE FORMULA FOR THE INVARIANT OF THE TREFOIL

In this section we give the omitted details of how equation (38) implies equation (39). We start with equation (38), and observe that

\[
\sum_{s_1, s_2, s_3 \in \mathbb{Z}} (-q)^{s_1 + s_2 + s_3} E_2^{(a)} E_3^{(a)} E_2^{(a)} E_3^{(s_1)} E_3^{(s_2)} E_3^{(s_3)} F_2^{(a)} F_2^{(a)} F_2^{(a)} 1_{(n,n,0)}
\]

\[
= \sum_{s_1, s_2, s_3 \in \mathbb{Z}} (-q)^{s_1 + s_2 + s_3} E_2^{(a)} E_3^{(a)} E_2^{(a)} E_3^{(s_1)} E_3^{(s_2)} E_3^{(s_3)} E_3^{(1-n-a-n-a-a,0)} F_2^{(a)} F_2^{(a)} F_2^{(a)} 1_{(n,n,0)}
\]

where we used (13) to include the idempotent in the middle term (and the fact that \((n, n, 0) - a\alpha_1 - 2a\alpha_2 - a\alpha_3 = (n - a, n - a, a)\). The term in parenthesis can be simplified as follows.

\[
E_3^{(s_1)} E_3^{(s_2)} E_3^{(s_3)} F_2^{(a)} F_2^{(a)} F_2^{(a)} 1_{(n-n-a, a, a)}
\]

\[(13) \quad \Rightarrow \quad H(a-s_1)H(a-s_2)H(a-s_3)E_3^{(s_1)} E_3^{(s_2)} E_3^{(s_3)} F_2^{(a)} F_2^{(a)} F_2^{(a)} 1_{(n-n-a, a, a)}
\]

\[(14a) \quad \Rightarrow \quad H(a-s_1)H(a-s_2)H(a-s_3) \sum_{s_4, s_5} [s_2 + s_3] [s_4] E_3^{(s_1)} E_3^{(s_2)} E_3^{(s_3)} F_2^{(a)} F_2^{(a)} F_2^{(a)} 1_{(n-n-a, a, a)}
\]

\[(13) \quad \Rightarrow \quad H(a-s_1)H(a-s_2)H(a-s_3) \sum_{s_4, s_5} [s_2 + s_3] [s_4] E_3^{(s_1)} E_3^{(s_2)} E_3^{(s_3)} F_2^{(a)} F_2^{(a)} F_2^{(a)} 1_{(n-n-a, a, a)}
\]

\[(14a) \quad \Rightarrow \quad H(a-s_1)H(a-s_2)H(a-s_3) \sum_{s_4, s_5} [s_2 + s_3] [s_4] E_3^{(s_1)} E_3^{(s_2)} E_3^{(s_3)} F_2^{(a)} F_2^{(a)} F_2^{(a)} 1_{(n-n-a, a, a)}
\]
\[ \sum_{s_4,s_5,s_6} \left[ s_2 + s_1 \left[ s_2 + s_1 \left[ s_1 + s_2 + s_3 - s_4 - s_5 \left[ s_1 + s_2 - s_4 \right] \right] \right] \right] \times \left[ s_2 + s_3 - s_5 \right] \left[ s_1 + s_2 + s_3 - s_4 - s_5 - s_6 \right] P_{s_3}^{(s_1 + s_2 + s_3 - s_4 - s_5 - s_6)} 1_{(n-a,n-a,a,a)} \]

Then to complete the computation of \( Y_0(a) 1_{\vartheta} \) from equation (58), set \( \tau = s_1 + s_2 + s_3 - s_4 - s_5 - s_6 \) for simplicity and use the above computation to simplify each term in the sum from (58)
and the relation that a disjoint trivial knot can be removed from a diagram at the expense of multiplication with $x = \frac{x-1}{q-q^{-1}}$. The product $L_1 L_2$ of two links diagrams is the obtained by
placing $L_1$ atop $L_2$. When $\Sigma$ is a disk, $S(\Sigma) \cong \mathbb{Q}(q, x)$ via a map $L \to \langle L \rangle$, where $\langle L \rangle$ is a framed version of the HOMFLYPT polynomial.

The HOMFLYPT skein algebra of the annulus contains the subalgebra $\mathcal{C}^+$ generated by the closure of all braids. It is known that $\mathcal{C}^+$ is isomorphic to the algebra of symmetric functions (with ground ring $\mathbb{Q}(q, x)$). Under this isomorphism, the Schur function $s_\lambda$ of a partition $\lambda$ corresponds to a certain skein element $Q_\lambda$ which will be recalled later. The relation with the colored HOMFLYPT polynomial is as follows. For an oriented link diagram $L$ on the disk with $r$ ordered components, and for partitions $\lambda_i$ for $i = 1, \ldots, r$ we have:

\begin{equation}
W_L(\lambda_1, \ldots, \lambda_r) = \langle L \ast (Q_{\lambda_1}, \ldots, Q_{\lambda_r}) \rangle
\end{equation}

Here, $L \ast (Q_{\lambda_1}, \ldots, Q_{\lambda_r})$ is the $\mathbb{Q}(q, x)$-linear combination of link diagrams on the disk obtained by replacing the $i$th component of $L$ by $Q_{\lambda_i}$. The above equality implies part (b) of Proposition 2.4.

Let $\sigma : \mathbb{Q}(x, q) \to \mathbb{Q}(x, q)$ denote the $\mathbb{Q}$-algebra automorphism given by $\sigma(x) = x$, $\sigma(q) = -q^{-1}$. One can easily check that $\sigma$ extends to a $\mathbb{Q}$-linear automorphism of $S(\Sigma)$ for any $\Sigma$ by setting $\sigma(L) := L$ for any link diagram $L$ on $\Sigma$. It is easy to see that $y$ is an element of the HOMFLYPT skein algebra of the disk, then

\begin{equation}
\sigma(\langle y \rangle) = \langle \sigma(y) \rangle.
\end{equation}

**Lemma B.1.** For any partition $\lambda$ one has

\begin{equation}
\sigma(Q_\lambda) = Q_{\lambda^t}.
\end{equation}

**Proof.** In [AM98], Morton-Aiston gave a geometric description of $Q_\lambda$ in terms of closures of braids. Let us recall this formula for partitions with one row $h_a = (a)$ or one column $e_a = (1^a)$ from [AM98, p.11]:

\begin{equation}
Q_{(a)} = \frac{1}{\alpha(a)} \sum_{\pi \in \text{Sym}_a} q^{l(\pi)} \tilde{\omega}_\pi, \quad Q_{(1^a)} = \frac{1}{\alpha(1^a)} \sum_{\pi \in \text{Sym}_a} (-q^{-1})^{l(\pi)} \tilde{\omega}_\pi.
\end{equation}

Here, for a permutation $\pi$ of $\text{Sym}_n$, $\omega_\pi$ denotes the positive braid corresponding to $\pi$, and $\tilde{\omega}_\pi \in \mathcal{C}$ denotes the closure of $\omega_\pi$. Moreover, $\alpha_\lambda$ is given by [AM98, p.14]

\begin{equation}
\alpha_\lambda = \prod_{(i,j) \in \lambda} q^{j-i \text{hook}(ij)}
\end{equation}

where hook$(ij)$ is the hook-length of the cell $(i, j)$ of the partition $\lambda$.

From Equations (64) and (65) one can readily check that $\sigma(Q_{(a)}) = Q_{(1^a)}$, proving the lemma for the case $\lambda = h_a = (a)$. The case of general $\lambda$ can be proved similarly, using explicit formulas of $Q_\lambda$ as described in [AM98]. Alternatively, one can reduce the general case to the case of one row as follows. The two Jacobi-Trudy formulas

\begin{equation}
s_\lambda = \det \left( (h_{\lambda_i+j-1})_{i,j=1}^\ell \right), \quad s_{\lambda^t} = \det \left( (e_{\lambda_i+j-1})_{i,j=1}^\ell \right),
\end{equation}

together with the case $\lambda = h_a$ implies the lemma for general partitions.
Suppose $L$ is an oriented link diagram $L$ on the disk with $r$ ordered components, and $\lambda_i$ for $i = 1, \ldots, r$ are partitions. We have

\[
\sigma(W_L(\lambda_1, \ldots, \lambda_r)) = \sigma(\langle L^*(Q_{\lambda_1}, \ldots, Q_{\lambda_r}) \rangle) \quad \text{by (61)}
\]

\[
= \langle L^*(Q_{\lambda_1}, \ldots, \sigma(Q_{\lambda_r})) \rangle \quad \text{by (62)}
\]

\[
= \langle L^*(\sigma(Q_{\lambda_1}^\dagger), \ldots, Q_{\lambda_r}^\dagger) \rangle \quad \text{by (63)}
\]

\[
= W_L(\lambda_1^\dagger, \ldots, \lambda_r^\dagger).
\]

This concludes the proof of part (c). \hfill \Box

### Appendix C. The recursion for the colored HOMFLYPT of the trefoil

Let $\lambda \in \mathcal{P}_{n-1}$ be a partition of length $\leq n - 1$. We also use $\lambda$ to denote the corresponding $U_q(sl_n)$-module. For every positive integer $k$, the theory of ribbon categories gives a representation $J : \mathcal{B}_k \to \text{Aut}(\lambda^\otimes k)$, where $\mathcal{B}_k$ is the braid group on $k$ strands and $\text{Aut}(\lambda^\otimes k)$ is the group of $U_q(sl_n)$-linear automorphisms of $\lambda^\otimes k$.

Suppose $\beta \in B_m$ is a braid on $m$ strands, and $L = \text{cl}(\beta)$ is the oriented framed link obtained by closing $\beta$ in the standard way, with blackboard framing. Then

\[
J_L(\lambda, \lambda, \ldots) = \text{tr}_{q}^{\lambda^\otimes m}(J(\beta)),
\]

where for a $U_q(sl_n)$-linear map $f : V \to V$,

\[
\text{tr}_V^f(f) = \text{tr}(fg, V).
\]

Here the right hand side is the usual trace of $fg$ acting on $V$, and $g \in U_q(sl_n)$ is the so-called charm element whose exact formula is not needed here. In particular, for a finite-dimensional weight a $U_q(sl_n)$-module $V$, the quantum dimension $\dim_q(V) := J_U(V)$ (where $U$ is the unknot) is

\[
\dim_q(V) := \text{tr}_{q}^V(\text{id}) = \text{tr}(g, V).
\]

Let $\sigma$ be the standard generator of $\mathcal{B}_2$ (see $X_{a,b}$ of Figure 1). Then $J(\sigma)$ is defined by the universal $R$-matrix and the action of $J(\sigma)$ on $h_m^\otimes 2$ can be calculated as follows. The decomposition of $h_m^\otimes 2$ into irreducible $U_q(sl_n)$-modules has the form

\[
h_m^\otimes 2 = \bigoplus_{k=0}^{m} \mu_{m,k},
\]

where $\mu_{m,k}$ is the partition $(2m - k, k)$. Since $J(\sigma)$ is $U_q(sl_n)$-linear, Schur lemma shows that there are scalars $c_{m,k} \in \mathbb{Q}(q^{1/n})$ such that on $h_m^\otimes 2$,

\[
J(\sigma)|_{h_m^\otimes 2} = \bigoplus_{k=0}^{m} c_{m,k} \text{id}_{\mu_{m,k}}.
\]

One of the axioms of the ribbon structure of $U_q(sl_n)$ is that

\[
J(\sigma^2)|_{V^\otimes W} = (r_V^{-1} \otimes r_W^{-1})r_V^\otimes W,
\]
where \( r \) is the ribbon element, which belongs to the center of a certain completion of \( U_q(\mathfrak{sl}_n) \) and acts on any finite-dimensional weight \( U_q(\mathfrak{sl}_n) \)-module, see [Tur94, Oht02]. Geometrically, \( r = J_T \), where \( T \) is the trivial 1-1 tangle with framing 1, and its action on \( \lambda \) is known (see e.g. [Lë00, Equ 1.7]):

\[
(69) \quad r|_{V_\lambda} = r(\lambda)\text{id}_\lambda, \quad \text{where } r(\lambda) = q^{\langle \lambda, \lambda + 2\rho \rangle}.
\]

Here \( \langle \cdot, \cdot \rangle \) is the inner product on the weight space of \( U_q(\mathfrak{sl}_n) \) normalized such that each root has square length 2, and \( 2\rho \) is the sum of all positive roots.

Using (68) in the square of (67), we get

\[
(c_{m,k})^2 = r(\mu_{m,k}) r(h_m)^{-2}.
\]

Taking the square root and using (69), one gets the value of \( (c_{m,k}) \), up to sign \( \pm 1 \). The sign can be determined by noting that when \( q = 1 \), \( J(\sigma) \) is the permutation, \( J(\sigma)(x_1 \otimes x_2) = x_2 \otimes x_1 \). Eventually, we get

\[
(70) \quad c_{m,k} = (-1)^k q^{-m^2/n} q^{m^2-2mk+k^2-k}.
\]

Suppose \( T_s \) is the link closure of \( \sigma^s \), which is a torus link of type \((2, s)\). By (66) and the decomposition (67),

\[
(71) \quad W_{T_s}(h_m) = q^{sm^2/n} J_{T_s}(h_m) = q^{sm^2/n} \sum_{k=0}^m (c_{m,k})^s \dim(q(\mu_{m,k}))
\]

where \( x = q^n \). In the last equality we use the well-known formula for the quantum dimension, see e.g. [ML03, Equ. (11)], which was first established by Reshetikhin. The right hand side of (71) gives a formula for \( W_{T_s}(h_m) \). When \( s = 3 \), we get another formula of \( W_{T_3} \) for the trefoil, which is simpler than the one given in Section 3.7, since it is a one-dimensional sum.

For odd \( s \), let \( T_s \) be the torus knot \( T_s \) with 0 framing. Then, adjusting the framing, from (71) we get

\[
(72) \quad W_{T_s}(h_m) = \sum_{k=0}^m (-1)^k q^{s(-m-2mk+k^2-k)} \left[ x; 2m-k-1 \atop 2m-k \right] [2m-2k+1][2m-k+1].
\]

Using the Zeilberger algorithm [PWZ96], we get the recurrence relation for \( W_{T_3}(h_m) \) as described in Section 1.4.
