A biodegradable film based on cellulose and thiazolidine bearing UV shielding property

Rasha A. Baseer1, Sawsan Dacrory2*, Mohamed A. M. El Gendy3, Ewies F. Ewies4 & Samir Kamel2

The current rationale is exploring new eco-friendly UV-shielding films based on cellulose and thiazolidine. Cellulose was oxidized to dialdehyde cellulose (DAC) and tricarboxy cellulose (TCC) by periodate and TEMPO/periodate/hypochlorite, respectively. While E-3-amino-5-(phenyldiazenyl)-2-thiothiazolidin-4-one (TH) was synthesized by coupling diazonium salt with the 5-methylene of 2-thioxo-4-thiazolidinone. DAC was then coupled with TH via Schiff base reaction and incorporated onto TCC with different ratios to get UV-shielding films. 1HNMR, infrared spectroscopy (FTIR), and thermal gravimetric analysis (TGA) were used to investigate the chemical structure of the synthesized materials. In addition, the films' morphology, thermal, mechanical, and UV-shielding properties were investigated. The UV-shielding studies revealed that the film with 10% DAC-TH has 99.88, 99.99, and 96.19% UV-blocking (UVB), UV-absorbance (UVA), and Ultra-violet protection (UPF), respectively. Moreover, the prepared films demonstrated promising antimicrobial activity against Escherichia coli, S. aureus, P. aeruginosa, and Candida albicans. Finally, the prepared films showed no cytotoxic effects on normal human skin fibroblast's HFB-4 cell line.

For the last decades, polymer films have been widely applied as packaging materials in many primary industries such as food, drugs, and electronic devices for their significant low cost, lightweight, good elasticity, and high transmittance1,2. However, scientists have turned to create biodegradable materials with the mounting voices calling for environmental conservation and the trend to use friendly materials3,4. These materials, obtained from renewable sources, are pure polymer, composite or blended products, and they could be classified as green polymer. Recently, cellulose materials have emerged as a strong alternative to synthetic polymers due to their unique biocompatible, biodegradable, non-toxic, and allergen-free5. Depending on its functional group that can be inserted into its chains backbone via the suitable modification. It looks most promising material and plays an important role in many applications such as drug delivery6,7, conductive materials8,9, Fertilizers agents10, and water treatment11. Dialdehyde cellulose (DAC) is the most widely utilized oxidized cellulose with highly reactive sites. Periodate is widespread to oxidize cellulose to dialdehyde cellulose12,13. It oxidizes the vicinal hydroxyl groups of cellulose at C2 and C312. In recent years, dialdehyde cellulose has received increasing attention as an ideal crosslinking agent whose aldehyde groups can crosslink with NH2 of the amino acid via Schiff’s base interaction12.

On the other hand, the building of UV-block cellulose films became an urgent need for further development and applications as biodegradable and eco-friendly UV-shielding materials13,14. Many approaches have been performed to develop UV-shielding cellulose through thermal treatment technology, presented as a green and straightforward approach for preparing UV-block cellulose. However, this method depends on the yellow discoloration of cellulose fibers during the treatment15,16. Moreover, UV absorbers are considered the dominant technology to achieve high UV protection via incorporating them into cellulose films. In this context, the development of highly efficient cellulose-based UV-shielding films has the scientist’s great attention17. Organic and inorganic UV-absorbers are mostly incorporated into cellulose films to achieve UV protection depending on the type of functional group inserted in its chain backbone18.

On the other hand, heterocyclic compounds can be found in natural and synthetic materials and are mainly known for their significant UV-absorbing property. 3-amino-2-thioxothiazolidin-4-one, commonly known as rhodamine, has a broad spectrum of biological activities demonstrating anti-septic, anti-inflammatory, antiparasitic, antifungal, antidiabetic, antiviral, and antineoplastic activity. Many studies were performed on rhodamine derivatives to prove antimicrobial activity. Also, their azo derivatives are used as a spectrophotometric chemosensor for Fe(III) with optical properties.

Based on this survey herein, we aim to synthesize E-3-amino-5-(phenyl diazenyl)-2-thioxothiazolidin-4-one (TH) and couple it with dialdehyde cellulose (DAC) to exploit the dual π bond of each of the aryl azo group, thioxothiazolidin-4-one, and the aldehyde oxime of DAC resulted from Schiff base beside to the lone pair of nitrogen, sulfur, oxygen which overlap arising to the splitting of the originally degenerate n orbitals to promote high UV absorbance material. It is incorporated with different ratios into tricarboxylic cellulose (TCC) to formulate biodegradable and antibacterial film with UV-shielding and high safety when tested on normal human skin fibroblasts viability. The mechanical, morphology, UV-absorbance and thermal properties of the produced film have been evaluated.

Materials and methods

Materials. Bleached bagasse pulp was supplied from Quena Company of Paper Industry, Egypt, with chemical composition, cellulose (96%), hemicellulose (3%), and lignin (3%). Dulbecco’s modified Eagle’s medium (DMEM), [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide] (MTT), Sodium meta periodate (NaIO₄), NaBr, and 2,2,6,6-tetramethylpiperidine-1-oxyl (TEMPO) were purchased from OXFORD LAB FINE CHEM LLP (Navghar, Vasai East, Maharashtra, India). Penicillin−streptomycin, amphotericin B, trypsin/EDTA solution, L-glutamine, and fetal bovine serum (FBS) were obtained from Invitrogen (Carlsbad, CA, USA). Doxorubicin HCl (Adricin®) was purchased from EBEWE Pharma (Unterach, AUSTRIA). Tissue culture flasks and tissue culture plates were purchased from Cole-Parmer(UK). All chemicals and reagents were used in analytical grade without any purification required before use.

Methods. Synthesis of E-3-amino-5-(phenyl diazenyl)-2-thioxothiazolidin-4-one (TH). In a reaction vessel, 5.1 mmol of sodium nitrite solution was dropped wisely for 10 min to the cooled solution of aniline (5 mmol) and 25 mL of aqueous hydrochloric acid solution (12 M, 32.19 mmol). The produced diazonium chloride was preserved at 0–5 °C; after that, an ethanolic solution (25 mL) of 2-thioxothiazolidinone (5 mmol) and sodium acetate (5 mmol) was added dropwise over 20 min. The resulting sludge mixture was stirred for 2 h at 5 °C before remaining standing overnight. The obtained dark brown precipitate (TH) was filtered, washed with water many times, and recrystallized by hot ethanol as shown in Fig. 2. MS m/z: 252 (81%).

Oxidation of cellulose to dialdehyde cellulose (DAC). Dialdehyde cellulose was prepared by oxidation of cellulose by sodium periodate under the effect of a microwave. Briefly, in 20 mL distilled water 1.5 g of cellulose was dispersed, followed by adding 2 g of sodium periodate, and pH was adjusted to 3. The precursor was transferred to the domestic microwave (power 800 W) for 1.5 min. The oxidized product (dialdehyde cellulose) was filtered, dispersed, followed by adding 2 g of sodium periodate under the effect of a microwave. Briefly, in 20 mL distilled water 1.5 g of cellulose was washed with ethanol several times, and recrystallized by hot ethanol as shown in Fig. 2. MS m/z: 252 (81%).

In the first step; to water-dispersed cellulose (5 g/ 500 mL), 0.08 g (0.5 mmol) of TEMPO reagent and 0.8 g (8 mmol) sodium bromide were added, followed by 50 mL (10%) of sodium hypochlorite solution and adjusting the pH to 10 with stirring overnight. At the end of the reaction, the solution was neutralized and centrifuged at 7000 rpm, and washed with water. Finally, it was dialyzed for 1 week against water to complete the TEMPO-oxidized cellulose purification process. In the second step, sodium periodate was added to suspend TEMPO-oxidized cellulose (1% consistency). To prevent the photo-induced decomposition of the periodate, the reaction container was wrapped with aluminum foil. After 3 h, the reaction was terminated by adding ethylene glycol, washed with distilled water, and filtered, giving dialdehyde carboxy cellulose.

In the second step, the mixture of acetic acid (20%) and sodium chlorite solution was added slowly to a suspended dialdehydedecarboxy cellulose (4.5% consistency), giving yellowish color and stirring for 48 h at ambient temperature. Eventually, the induced tricarboxy cellulose (TCC) was In the third step, a mixture of acetic acid (20%) and sodium chlorite solution was slowly added to a suspended dialdehydedecarboxy cellulose (4.5%), producing a yellowish colour and stirring for 48 h at room temperature. Eventually, the induced tricarboxy cellulose (TCC) was scrubbed with deionized water and filtered. TCC carboxylate content was calculated using the electric conductivity titration method by merging 50 mg of the dried sample with 0.01 M HCl (15 mL) and deionized water (20 mL). The mixture was stirred to achieve a well-dispersed suspension. Titration with 0.01 M NaOH aqueous...
The inhibition percentages were calculated for the crude antimicrobial material using the serial dilution method via colony formation unit (CFU) technique according to the procedure described by Abdelraof et al.36.

**Preparation of TCC/DAC-TH film.** Different ratios of DAC-TH (2.5, 5, 7, and 10% based on the total weight of the film) were added into an aqueous dispersion TCC solution with drops of the glycerol as a plasticizer followed by sonication for 10 min, 30% P. The resulting TCC/DAC-TH suspension was poured into Teflon dishes and dried at 60 °C for 24 h.

**Characterization.** FTIR spectra were performed on a Beckman infrared spectrophotometer PU 7712 using a KBr disk (United States). The scans recorded were the average of 100 scans and the selected spectral range between 500 and 4000 cm⁻¹. The ¹H NMR spectra were measured on Bruker AVANCE 400 MHz spectrometer (Bruker) with a 5 mm BBFO probe using deuterated dimethyl sulfoxide (DMSO-d6) as the solvent (Germany). Morphological studies have been measured using a scanning electron microscope (SEM) (Hitachi High Technologies America, Schaumburg, IL). The thermal behavior (TGA/DSC) is performed via (Perkin Elmer thermogravimetric analyzer (Waltham, Massachusetts, USA) under nitrogen conditions heating rate was 10 °C/min from 50 to 500 °C.

The mechanical properties of the prepared films were investigated using Universal Testing Machine model 4201 from Instron®. The stress–strain curve of films was tested on 6 cm film bars (width 15 mm; length 20 mm) with a Lloyd instrument (Lloyd Instruments, West Sussex, United Kingdom) with 5-N load cell measurements at ambient temperature.

The UV-blocking properties of the TCC/DAC-TH films were performed by measuring their absorbance and total transmittance with a Shimadzu UV-3600 spectrometer from 200 to 2500 nm (UV–Vis–NIR spectrum, Japan). The T (UVA) and T (UVB) of the TCC/DAC-TH films were calculated using the following equations:

\[
T(UVA)\% = 100 - \frac{\int_{320}^{400} T_\lambda \times d\lambda}{\int_{320}^{400} d\lambda}
\]

\[
T(UVB)\% = 100 - \frac{\int_{280}^{320} T_\lambda \times d\lambda}{\int_{280}^{320} d\lambda}
\]

The UV-protection factors (UPF) of films were measured by the AATCC 183–2010 using a UV–vis spectrophotometer, where \( T_\lambda \) is the light transmittance of TCC/DAC-TH films. The air was used as the control reference. UPF was measured from the transmission spectra of the films in the range of 290–400 nm using the following equation:

\[
UPF = \frac{\sum_{290}^{400} E(\lambda) \cdot S(\lambda) \cdot T(\lambda) \cdot \Delta(\lambda)}{\sum_{290}^{400} E(\lambda) \cdot S(\lambda) \cdot \Delta(\lambda)}
\]

where \( E(\lambda) \) is the relative erythemal spectral effectiveness, \( S(\lambda) \) is the solar spectral irradiance in Wm⁻² nm⁻¹. The values were provided by the National Oceanic and Atmospheric Administration database (NOAA)), \( T(\lambda) \) is the spectral transfer of the data taken from UV spectrophotometric tests, and \( \Delta(\lambda) \) is the variation among observable wavelengths.

**Evaluation of the antibacterial activities.** Using nutrient broth medium, the microbial activity of TCC/DAC-TH films was quantified against I Gram-negative bacteria: Escherichia coli (NCTC-10416); (ii) Gram-positive bacteria: Staphylococcus aureus (NCTC-7447); and (iii) unicellular fungi: Candida albicans (NCCLS 11). according to Hamed et al.35. The inhibition percentages were calculated for the crude antimicrobial material using the serial dilution method via colony formation unite (CFU) technique according to the procedure described by Abdelraof et al.36.

**Cell culture and determination of cell viability.** Human skin fibroblasts HFB-4 cell line was obtained from the Egyptian National Cancer Institute, Cairo University, Egypt. The cells were maintained in DMEM media supplemented with 10% heat-inactivated FBS, 2 mM L-glutamine, 100 IU/mL penicillin, 100 μg/mL streptomycin, and 0.25 μg/mL amphotericin B. Cultures were grown in 75cm² tissue culture flasks at 37 °C in a humidified incubator with 5% CO2 and subcultured every 3–5 days.

Cells were treated with increasing concentrations of each treatment. As previously described, viability was calculated by monitoring the ability of reducing enzymes existing in viable cells to convert MTT to formazan.
crystals. Briefly, HFB-4 cells were suspended in DMEM media supplemented with 10% heat-inactivated FBS and were plated in 96-well flat-bottom cell culture plates with a density of 3 × 10⁴ cell per well. The plates were incubated for 24 h at 37 °C in a 5% CO₂ humidified incubator till 70% confluency. After that, media were replaced with serum free media containing 12.5, 25, 50, and 100 mcg/mL of each film, TCC, DAC-TH or doxorubicin as a positive control (100 µg/mL) that showed more 75% cytotoxicity, and the plates were incubated at 37 °C in a CO₂ humidified incubator. Twenty-four h later, media were removed, and 100 μL of MTT solution (1.2 mM in PBS) was added to each well. After 4 h incubation, isopropyl alcohol (100 μL) was added to each well, and the plates were placed in a plate shaker for 1 h. Using a BIO-TEK Instruments EL 312e microplate reader (Bio-Tek Instruments, Winooski, VT), the blue color constituted in each well was estimated at 570 nm with a reference wavelength of 690 nm. Results were expressed as a percentage of cell viability relative to DMSO-treated control wells designated as 100% viable cells, and the experiment was repeated 2 times.

Statistical analysis. Cell viability data are summarized as mean ± S.E.M., and statistical analysis for viability bar graphs per each experimental group was performed using one-way ANOVA pursued by Student–Newman–Keuls post hoc test in Sigma Stat 3.5 for Windows, Systat Software Inc. (San Jose, CA).

Ethical approval. The cell experiments were consistent with the protocols adopted by the local ethical committee (Ethical Committee of National Research Centre).

Results and discussion

Chemistry. As presented in Fig. 1, TCC/DAC-TH film was prepared in several steps and evaluated as a UV-shielding, where the assumed synthetic mechanisms of TH, DAC, DAC-TH, and TCC/DAC-TH films are outlined in Figs. 2, 3, 4. TH was synthesized from the reaction of the diazonium salt with the 5-methylene of 2-thioxo-4-thiazolidinone through a coupling reaction (Fig. 2) with a yield of 81%. As apparent in Fig. 3, DAC has successfully synthesized via periodat oxidation with dialdehyde content 60%. As is well known, reactive aldehyde functionalities can exist as hydrates, hemialdals, and hemiacetals. The intra-chain and intra-anhydroglucose unit hemiacetal structure are feasible among C2/C6 and C3/C6 and hemialdal C2/C3. In addi-
tion, DAC-TH was prepared via a Schiff base reaction as presented in Fig. 3. An amine reacted with a carbonyl compound (DAC) via nucleophilic addition, and then dehydration formed hydrated cellulose aldehyde. Also, according to a previous study, Scheme 3 defines the suggested mechanism of formation of TCC with carboxyl contents of 2 ± 0.3 mmol/g\(^30\). In the presence of sodium bromide and sodium hypochlorite, TEMPO performs as a mediator as selectively oxidation of the primary hydroxyl groups (C6). After that, hydroxyl groups in C2 and C3 were oxidized to the aldehyde groups using periodate, which further oxidized to generate TCC.

The afforded TH, DAC, and DAC-TH were confirmed by \(^1\)HNMR and FT-IR (Fig. 5). As evident, \(^1\)HNMR of TH reveals the presence of peaks at δ 11.22 (s, 2H, NH\(_2\)), 7–7.36 (m, 5H, Ar–H), and 5.92 (s, 1H, CH thiazole). On the other hand, \(^1\)HNMR of DAC-TH induces the presence of peaks at δ 7.28 (m, 5H, Ar–H), 6.99 (m, CH, hydrazide), 4.99 (m, 1alpha –O from methine), 4.20 (m, Ibeta –O–C from methylene), 3.58 (m, CH\(_2\)), 3.02 (m, CH glucose), and 2.38 (m, 1H, OH). Also, Fig. 5 shows significant FTIR spectra for TH, DAC, DAC-TH, TCC, and TCC/DAC-TH film. FTIR spectra of DAC, TH, and DAC-TH reveal a band at 3320 cm\(^{-1}\) related to (OH) for both DAC and DAC-TH\(^39\), a band at 3300 cm\(^{-1}\) assigned to (NH\(_2\)) of TH\(^40\), a band at 2943 cm\(^{-1}\) corresponding to (C–H vibration), 1680 cm\(^{-1}\) regarding C=O stretching δ-lactam, the band at 1630 cm\(^{-1}\) is due to C=O in DAC, due to hemiacetal bond formation (between aldehyde groups and their adjacent hydroxyl groups OH), so sometimes this peak can be very small and hidden due to presence DAC in the hydrated form\(^41,42\). The band at 1610 cm\(^{-1}\) regarding to both (N=N) and (C=N)\(^43\), 1360 cm\(^{-1}\) for C–N, 1230 cm\(^{-1}\) for C=S\(^43\) and 1030 cm\(^{-1}\) related to –C–O–C pyranose ring skeletal vibration\(^44\). Also, bands at 1733, 1615, 1230, and 1024 cm\(^{-1}\) attributed to stretching δ-lactam, carboxylate groups, C=S, and –C–O–C pyranose ring skeletal vibration, respectively\(^40,44\) (Fig. 5).

Thermogravimetric analysis. The thermogravimetric analysis (TGA) of TCC films with 0, 2.5, and 10% DAC-TH is presented in Fig. 6. As apparent, three stages of degradation are observed for both TCC and TCC/10%DAC-TH. At the first stage of TCC thermal degradation, the wt loss is about 7% at 68–169 \(^\circ\)C, attributed to water evaporation. The second stage is the degradation initiation temperature of TCC, which occurs from 169–330 \(^\circ\)C and the wt loss is 47% due to the formation of CO\(_2\), H\(_2\)O, and CO\(^35\). Finally, the residual solid
is approximately 35% at the final stage ranging from 330–600 °C. In comparison, TCC/10% DAC-TH shows 11% wt loss in the region from 47–179 °C for water evaporation and 53% wt loss at 179–308 °C due to DAC oxime. Finally, the residual solid is approximately 35% at the final stage ranging from 330–600 °C. At the same time, TCC/10% DAC-TH shows 11% wt loss in the region from 47–179 °C for water evaporation and 53% wt loss at 179–308 °C due to DAC oxime and azo degradation besides the formation of CO₂, H₂O, and CO. The final residual solid is approximately 30% in the region from 308–600 °C. Eventually, TCC/2.5% DAC-TH shows four degradation stages despite TCC/10% DAC-TH. That may explain by increasing the crosslinking results from hydrogen bonding between TCC and DAC as DAC concentration increases. Accordingly, TCC/DAC-TH shows high thermal stability at a higher concentration of DAC-TH rather than less concentration. In comparison, TCC/2.5% DAC-TH shows 12% wt loss for water evaporation at a temperature from 64–190 °C and 26% wt loss.

Figure 5. $^1$HNMR of (a) TH and (b) DAC-TH. FTIR Spectra of (c) DA, TH, DA-TH, TCC, and (d) TCC/DAC-TH films.
Figure 5. (continued)

Figure 6. TGA of TCC films with 0, 2.5, and 10% DAC-TH.
Candida albicans showed that the 10% DAC-TH content inhibited 72, 64, and 66% of Escherichia coli, Staphylococcus aureus, and S. aureus respectively against common bacteria and fungi revealed a high inhibition effect\(^5\)\(^3\),\(^4\). Consequently, the thiazolidine have significant UV absorption properties\(^2\),\(^3\)\(^4\),\(^5\)\(^0\). Therefore, TH has been used to graft DAC and incorporated with different ratios of DAC-TH that were investigated at room temperature. As it seems, increasing DAC-TH ratios decreases the tensile strength and elongation of the prepared films. For example, tensile strength and elongation of TCC film were 6.5 MPa and 4 mm and decreased to 2.5 MPa and 2 mm, respectively, with the addition of DAC-TH. It may be attributed to crosslinking formation between TCC and DAC-TH that causes structure deformation; as a result, the crystallinity of the films decreases.

**Morphology and energy-dispersive X-ray spectroscopy (SEM/EDX) analysis.** The morphological structure of DAC fiber, TCC, and TCC/DAC-TH films are characterized via scanning electron spectroscopy (SEM). As presented in Fig. 7, DAC fiber seems like a hair cluster structure, while TCC film showed a smooth surface. Furthermore, TCC/DAC-TH film showed a rough, thick layer of DAC-TH with semi-uniform dispersion. On the other side, the existence of DAC-TH was confirmed by Energy Dispersive X-ray spectroscopic analysis (EDX). EDX ensures the significant elements of DAC-TH, where the EDX analysis of TCC showed two signals related to N and S opposite what TCC/DAC-TH film presents.

**Mechanical properties.** The ability of films to withstand external stress is one of the essential features of films, and mechanical properties control this ability Fig. 8 shows the stress/strain curves of TCC/DAC-TH films with different ratios of DAC-TH that were investigated at room temperature. As it seems, increasing DAC-TH ratios decreases the tensile strength and elongation of the prepared films. For example, tensile strength and elongation of TCC film were 6.5 MPa and 4 mm and decreased to 2.5 MPa and 2 mm, respectively, with the addition of DAC-TH. It may be attributed to crosslinking formation between TCC and DAC-TH that causes structure deformation; as a result, the crystallinity of the films decreases.

**UV-shielding performance.** UV absorbers have been widely used for UV-shielding improvement of films as the indispensable demand in several packaging industries\(^4\)\(^7\)\(^-\)\(^9\). As previously known, heterocyclic compounds such as the indispensable demand in several packaging industries\(^4\)\(^7\)\(^-\)\(^9\). As previously known, heterocyclic compounds show no cytotoxicity up to 100 mcg/mL when incubated with HFB-4 cells for 24 h. In contrast, DAC-TH showed no toxicity up to 100 mcg/mL when incubated with HFB-4 cells for 24 h. In contrast, DAC-TH showed no toxicity up to 100 mcg/mL when incubated with HFB-4 cells for 24 h. In contrast, DAC-TH showed no toxicity up to 100 mcg/mL when incubated with HFB-4 cells for 24 h. In contrast, DAC-TH showed no toxicity up to 100 mcg/mL when incubated with HFB-4 cells for 24 h. In contrast, DAC-TH showed moderate cytotoxicity that was statistically significant compared to vehicle-treated cells starting from 25 mcg/mL (Fig. 7a). Photographs were captured for all treatments at 100 mcg/mL, and the positive control, doxorubicin, after 24 h incubation period that reflected the safety of all the prepared film formulations (Fig. 11b).

Conclusion

In conclusion, a new antimicrobial/UV protection film based on cellulose and \( E-3\text{-amino-5-}(\text{phenyldiazenyl})-2\text{-thioxothiazolidin-4-one} \) was successively prepared. In addition to film preparation, the properties of the films, such as UV protection, mechanical, thermal, and biological, were studied. A high degree of UV protection appeared with 10% dialdehyde cellulose. The prepared films have demonstrated significant antibacterial activities and did not affect the cell viability of human skin fibroblasts. Thus, this product is synthetically important and possesses a wide range of promising applications like food packaging, skincare materials, and electronic device coating.

Acknowledgements
The authors thank the National Research Centre for the financial support. Also, they thank Dr. Mohamed Hasa-
nin, Department of Cellulose and Paper, National Research Centre, Egypt, for carrying out the antimicrobial
screening experiment.

Author contributions
The manuscript was written through the contributions of all authors. All authors have approved the final version
of the manuscript.

Funding
Open access funding provided by The Science, Technology & Innovation Funding Authority (STDF) in coopera-
tion with The Egyptian Knowledge Bank (EKB). Open access funding is provided by The Science, Technology &
Innovation Funding Authority (STDF) in cooperation with The Egyptian Knowledge Bank (EKB).

Competing interests
The authors declare no competing interests.
