A geometric approach to Conn’s linearization theorem

By Marius Crainic and Rui Loja Fernandes

Dedicated to Alan Weinstein

Abstract

We give a soft geometric proof of the classical result due to Conn stating that a Poisson structure is linearizable around a singular point (zero) at which the isotropy Lie algebra is compact and semisimple.

Introduction

Recall that a Poisson bracket on a manifold $M$ is a Lie bracket $\{\cdot,\cdot\}$ on the space $C^\infty(M)$ of smooth functions on $M$, satisfying the derivation property

$$\{fg,h\} = f\{g,h\} + g\{f,h\}, \quad f, g, h \in C^\infty(M).$$

Let us fix a zero of the Poisson bracket, i.e., a point $x_0 \in M$ where $\{f,g\}(x_0) = 0$, for all functions $f, g \in C^\infty(M)$. Then $T^*_{x_0}M$ becomes a Lie algebra with the Lie bracket:

$$[d_{x_0}f, d_{x_0}g] := d_{x_0}\{f,g\}.$$

This Lie algebra is called the isotropy Lie algebra at $x_0$ and will be denoted by $\mathfrak{g}_{x_0}$. Equivalently, the tangent space $T_{x_0}M = \mathfrak{g}_{x_0}^\ast$ carries a canonical linear Poisson bracket called the linear approximation at $x_0$. The linearization problem for $(M,\{\cdot,\cdot\})$ around $x_0$ is the following:

- Is there a Poisson diffeomorphism $\phi : U \to V$ from a neighborhood $U \subset M$ of $x_0$ to a neighborhood $V \subset T_{x_0}M$ of $0$?

When $\phi$ exists, one says that the Poisson structure is linearizable around $x_0$. The deepest known linearization result is the following theorem due to Conn [4]:

**Theorem 1.** Let $(M,\{\cdot,\cdot\})$ be a Poisson manifold with a zero $x_0 \in M$. If the isotropy Lie algebra $\mathfrak{g}_{x_0}$ is semisimple of compact type, then $\{\cdot,\cdot\}$ is linearizable around $x_0$.

MC was supported by the NWO-Vidi Grant 639.032.712 ("Poisson Topology"). RLF was supported in part by FCT/POCTI/FEDER and grant PTDC/MAT/098936/2008.
Note that there exists a simple well-known criterion to decide if $g_{x_0}$ is semisimple of compact type: its Killing form $K$ must be negative definite.

The proof given by Conn in [4] is analytic. He uses a combination of Newton’s method with smoothing operators, as devised by Nash and Moser, to construct a converging change of coordinates. This proof is full of difficult estimates and, in spite of several attempts to find a more geometric argument, it is the only one available up to now. See also the historical comments at the end of this paper.

In this paper we will give a soft geometric proof of this result using Moser’s path method. At the heart of our proof is an integration argument and an averaging argument. The averaging enters into the proof in a similar fashion to the proofs of other linearization theorems, such as Bochner’s Linearization Theorem for actions of compact Lie groups around fixed points. Our proof gives a new geometric insight to the theorem, clarifies the compactness assumption, and should also work in various other situations. More precisely, the proof consists of the following four steps:

**Step 1:** Moser’s path method. Using a Moser’s path method, we prove a Poisson version of Moser’s theorem (see Theorem 2), which is inspired by the work of Ginzburg and Weinstein [14]. It reduces the proof of Conn’s theorem to showing that the 2nd Poisson cohomology around $x_0$ vanishes.

**Step 2:** Reduction to integrability around a fixed point. Using the vanishing of cohomology for proper Lie groupoids and the general Van Est theorem relating groupoid and algebroid cohomology [5], we show that it is enough to prove integrability of the Poisson structure around a fixed point $x_0$.

**Step 3:** Reduction to the existence of symplectic realizations. Using the equivalence of integrability in the Poisson case and the existence of complete symplectic realizations [7], we show that it is enough to construct a symplectic realization of a neighborhood of $x_0$ with the property that the fiber over $x_0$ is 1-connected and compact.

**Step 4:** Existence of symplectic realizations. The same path space used in [6] to determine the precise obstructions to integrate a Lie algebroid and to explicitly construct an integrating Lie groupoid, yields that a neighborhood of $x_0$ admits the desired symplectic realization.

The fact that the tools that we use only became available recently probably explains why it took more than 20 years to find a geometric proof of Conn’s theorem.

The four sections that follow describe each of the steps in the proof. We conclude the paper with two appendices: the first one contains an auxiliary proposition on foliations (which is used in the last step), while in the second we make some historical remarks.
Finally, we would like to mention that our method works in other situations as well. A similar linearization result around symplectic leaves instead of fixed points is being worked out in [18]. The analogue of Conn’s theorem for Lie algebroids (conjectured in [25] and proved in [20]) can also be proved by our method, the only missing step being the proof of the vanishing conjecture of [8] (one must replace the Poisson cohomology of Step 1 by the deformation cohomology of [8]). Details will be given elsewhere. It would also be interesting to find a similar geometric proof of the smooth Levi decomposition theorem of Monnier and Zung [20].

**Step 1: Moser’s path method**

Let us start by recalling that a Poisson bracket \{\cdot, \cdot\} on \(M\) can also be viewed as a bivector field \(\pi \in \Gamma(\wedge^2 TM)\) with zero Schouten bracket \([\pi, \pi] = 0\). One determines the other through the relation
\[
\pi(\mathrm{d}f \wedge \mathrm{d}g) = \{f, g\}, \quad (f, g \in C^\infty(M)).
\]
Recall also that the Poisson cohomology of \(M\) (with trivial coefficients) is the cohomology of the complex \((\mathfrak{X}^k(M), d_\pi)\), where \(\mathfrak{X}^k(M)\) is the space of \(k\)-vector fields, and the differential is defined by
\[
d_\pi \theta := [\pi, \theta].
\]
When \(x_0\) is a zero of \(\pi\), we can consider the local Poisson cohomology groups \(H^k_\pi(M; x_0)\). By this we mean the Poisson cohomology group of the germ of \((M, \pi)\) at \(x_0\), i.e., the group \(\lim_{\to U} H^k_\pi(U)\) obtained by taking the direct limit of the ordinary Poisson cohomology groups of \(U\), when \(U\) runs over the filter of open neighborhoods of \(x_0\).

**Theorem 2.** Let \((M, \{\cdot, \cdot\})\) be a Poisson manifold with a zero \(x_0\). Assume that the Lie algebra cohomology groups \(H^1(\mathfrak{g}_{x_0})\) and \(H^1(\mathfrak{g}_{x_0}, \mathfrak{g}_{x_0})\) vanish. If \(H^2_\pi(M; x_0) = 0\), then \(\{\cdot, \cdot\}\) is linearizable at \(x_0\).

For the proof, we will apply a Poisson version of Moser’s path method. Since this is a local result, we can assume that \(M = \mathbb{R}^n\) and \(x_0 = 0\). Also, to simplify the notation we denote by \(\mathfrak{g}\) the isotropy Lie algebra at 0. We consider the path of Poisson structures \(\pi_t\) on \(\mathbb{R}^n\) defined by the formula
\[
\pi_t(x) = \frac{1}{t} \pi(tx), \quad (t \in [0, 1]).
\]
Then \(\pi_1 = \pi\), while \(\pi_0 = \pi_{\text{lin}}\) is the linearization of \(\pi\) at the origin. Moser’s method will give us an isotopy \(\{\phi_t\}\), \(0 \leq t \leq 1\), defined in a neighborhood of the origin, and such that
\[
(\phi_t)_* \pi_t = \pi_{\text{lin}}, \quad (t \in [0, 1]).
\]
Therefore $\phi_1$ will be the desired linearization map. To construct $\phi_t$ let us consider the bivector field $\dot{\pi}_t := \frac{d\pi_t}{dt}$.

**Lemma 1.** There exists a vector field $X$ around the origin $0 \in \mathbb{R}^n$, whose first jet at 0 vanishes, such that
\[
(1) \quad \mathcal{L}_X \pi = -\dot{\pi}_1.
\]

**Proof.** Differentiating the equation $[\pi_t, \pi_t] = 0$ with respect to $t$, we obtain
\[
d_{\pi} \dot{\pi}_1 = [\pi, \dot{\pi}_1] = 0,
\]
so $\dot{\pi}_1$ is a Poisson 2-cocycle. Hence its restriction to a ball around the origin will be exact; i.e., we find a vector field $Y$ on the ball such that
\[
\dot{\pi}_1 = d_{\pi} Y.
\]
This relation has two consequences:

(a) Since $\dot{\pi}_1$ vanishes at 0, if we evaluate both sides on a pair of 1-forms and set $x = 0$, we see that $Y_0([\alpha, \beta]) = 0$, for $\alpha, \beta \in g$. Since $H^1(g) = 0$ (i.e. $[g, g] = g$), we conclude that $Y_0 = 0$. Let $Y_{\text{lin}}$ be the linearization of $Y$ at the origin.

(b) Since $\dot{\pi}_1$ has zero linearization at the origin, the linearization at 0 of our equation becomes
\[
d_{\pi_{\text{lin}}} Y_{\text{lin}} = 0.
\]
Note that the complex $X_{\text{lin}}^\bullet(V)$ of linear multi-vector fields on $V = \mathbb{R}^n$, endowed with $d_{\pi_{\text{lin}}}$, identifies canonically with the Eilenberg-Chevalley complex $C^\bullet(g, g)$ with coefficients in the adjoint representation. Hence, $Y_{\text{lin}}$ becomes a 1-cocycle in this complex; since $H^1(g, g) = 0$, $Y_{\text{lin}}$ must be exact, and so $Y_{\text{lin}} = d_{\pi_{\text{lin}}} v$ for some $v \in g = C^0(g, g) \cong X_{\text{lin}}^0(V)$. The vector field $X = Y - d_{\pi} v$ has the desired properties. $\square$

**Proof of Theorem 2.** If $X$ is a vector field as in the lemma, consider the time-dependent vector field $X_t(x) := \frac{1}{t} X(tx)$. From (1) we obtain immediately that
\[
\mathcal{L}_{X_t} \pi_t = -\dot{\pi}_t.
\]
Let $\phi_t$ be the flow of $X_t$. Since $X_t(0) = 0$, we see that $\phi_t$ is defined in some neighborhood $V$ of the origin for $0 \leq t \leq 1$. Also, we compute:
\[
\frac{d}{dt} (\phi_t)_* \pi_t = (\phi_t)_* \left( \mathcal{L}_{X_t} \pi_t + \frac{d\pi_t}{dt} \right) = 0.
\]
We conclude that $\phi_t$ is a diffeomorphism of $V$ with the desired property. $\square$
Step 2: Reduction to integrability around a fixed point

In this section we explain the statement and we prove the following proposition which, when combined with Theorem 2, reduces the proof of Conn’s theorem to integrability around a fixed point:

**Proposition 1.** Let \((M, \pi)\) be a Poisson manifold, \(x_0 \in M\) a fixed point. If some neighborhood of \(x_0\) is integrable by a Hausdorff Lie groupoid with 1-connected \(s\)-fibers, then

\[ H^2_\pi(M, x_0) = 0. \]

More precisely,

(i) There exist arbitrarily small neighborhoods \(V\) of \(x_0\) which are integrable by Hausdorff proper groupoids \(G \rightrightarrows V\) with cohomologically 2-connected fibers.

(ii) For any such \(V\), \(H^1_\pi(V) = H^2_\pi(V) = 0.\)

The geometric object behind the Poisson brackets which provides the bridge between Poisson geometry and Lie-group type techniques is the cotangent Lie algebroid \(\mathcal{A} = T^*M\) and the associated groupoid \(G(\mathcal{A})\) (see \([6], [7]\)). For a Poisson manifold \(M\) we will denote by \(\Sigma(M, \pi) = G(T^*M)\) its associated groupoid. We recall that \(\Sigma(M)\) is defined as the set of cotangent paths in \(M\) modulo cotangent homotopies, and that it is a topological groupoid with 1-simply connected \(s\)-fibers. A Poisson manifold \(M\) is said to be integrable if the associated Lie algebroid \(T^*M\) is integrable. This happens if and only if \(\Sigma(M, \pi)\) is a Lie groupoid. In this case, \(\Sigma(M, \pi)\) carries a natural symplectic structure, that makes it into a symplectic groupoid.

**Proof of Proposition 1.** Let us assume that \(U\) is a neighborhood of \(x_0\) which is integrable by a Hausdorff Lie groupoid \(G \rightrightarrows U\). The fiber of the source map \(s : G \to U\) above \(x_0\) is a Lie group integrating \(\mathfrak{g}_{x_0}\), so it is compact and 1-connected. Hence, by Reeb stability, there exists a neighborhood \(V_0\) of \(x_0\) such that \(s^{-1}(V_0)\) is diffeomorphic to the product \(V_0 \times G\). If we let \(V = t(s^{-1}(V_0)) \subset U\) be the saturation of \(V_0\), the restriction \(G_V\) of \(G\) to \(V\) will be a groupoid whose source map has compact, 1-connected, fibers; using right translations, each fiber will be diffeomorphic to \(s^{-1}(x_0) \simeq G\). Moreover, a compact Lie group has the same rational homology type as a product of odd dimensional spheres, so \(G\) is automatically cohomologically 2-connected, and so the \(s\)-fibers are also cohomologically 2-connected.

The proof of the second part is a combination of two classical results on Lie groups which have been extended to Lie groupoids. The first result states that the differentiable cohomology (defined using groups cocycles which are smooth) vanishes for compact groups, which follows immediately by averaging. This result extends immediately to groupoids, i.e. \(H^*_{\text{diff}}(G) = 0\) for any proper groupoid \(G\) (\([5, \text{Prop. 1}]\)).
The second result is the Van Est isomorphism. As explained in [5], differentiable group(oid) cocycles can be differentiated and they give rise to Lie algebra(oid) cocycles. The resulting map \( \Phi : H^k_{\text{diff}}(G) \to H^k(A) \), called also the Van Est map, is an isomorphism for degree \( k \leq n \) provided the \( s \)-fibers of \( G \) are cohomologically \( n \)-connected ([5, Th. 3]). Again, the proof is just an extension of the classical proof of Van Est.

If we apply these two results to our groupoid \( G \rightrightarrows V \), the second part of the proposition follows since the Poisson cohomology of \( V \) coincides with the Lie algebroid cohomology of \( A = T^*V \).

\[ \square \]

**Step 3: Reduction to the existence of symplectic realizations**

In the previous step, we reduced the proof of Conn’s theorem to integrability around a fixed point. The integrability of a Poisson manifold \( (M, \pi) \) is strongly related to the existence of symplectic realizations.

Recall that a symplectic realization of \( (M, \pi) \) consists of a symplectic manifold \( S \) together with a Poisson map \( \nu : S \to M \) which is a surjective submersion. One calls it complete if, for any complete Hamiltonian vector field \( X_f \) on \( M \), the vector field \( X_{\nu^*(f)} \) is complete. It is known that the existence of complete symplectic realizations is equivalent to integrability (Theorem 8 in [7]). However, that depends on subtleties regarding the (required) Hausdorff conditions on \( S \) which are not relevant for us since we are interested in Hausdorff Lie groupoids. Instead, in this paper we do require \( S \) to be Hausdorff and we extract from [7] the following result. In the statement we use the following conventions: for a symplectic realization \( \nu : S \to M \) we denote by \( F(\nu) \) the foliation of \( S \) by the (connected components of the) fibers of \( \nu \), and \( F(\nu)^\perp \) is its symplectic orthogonal. Also, we recall that a foliation is simple if it is induced by a submersion.

**Theorem 3.** A Poisson manifold \( (M, \pi) \) is integrable by a Hausdorff Lie groupoid with 1-connected \( s \)-fibers if and only if it admits a complete symplectic realization \( \nu : S \to M \) with the property that the foliation \( F(\nu)^\perp \) is simple and has simply connected leaves.

**Proof.** One direction is clear: the source map of a Lie groupoid as in the statement provides the desired symplectic integration (the symplectic orthogonal of the \( s \)-fibers are the \( t \)-fibers). Assume now that \( \nu : S \to M \) is a symplectic integration as in the statement. Theorem 8 in [7] insures that \( \Sigma = \Sigma(M, \pi) \) is smooth (but possibly non-Hausdorff). A simple remark on the proof of the cited theorem implies that, under our hypothesis, \( \Sigma \) is actually Hausdorff. Recall the main steps of the proof: the assignment \( X_f \mapsto X_{\nu^*(f)} \) induces an action of the Lie algebroid \( T^*M \) on \( S \) which integrates to an action of the Lie groupoid \( \Sigma \) on \( S \); the associated action groupoid is homeomorphic.
to the monodromy groupoid of $\mathcal{F}(\nu)^\perp$, which we denote by $\mathcal{G}(\mathcal{F}^\perp)$. In other words, we have
\[ \Sigma \times_M S \cong \mathcal{G}(\mathcal{F}^\perp), \]
where the fibered product is over $s$ and $\nu$. Since the right-hand side is smooth, it follows easily [7] that $\Sigma$ is smooth as well and the previous homeomorphism is a diffeomorphism. Finally, note that $\mathcal{F}^\perp$ is induced by a submersion $\pi : S \to B$, for some manifold $B$, and that its leaves are simply connected. Therefore, we see that $\mathcal{G}(\mathcal{F}^\perp) = S \times_B S$ is Hausdorff. We conclude that $\Sigma$ is Hausdorff as well. □

**Remark 1.** The proof actually shows that the conditions on $\mathcal{F}^\perp$ can be replaced by the condition that $\mathcal{F}^\perp$ has no vanishing cycles.

The following corollary reduces the proof of Conn’s theorem to the existence of symplectic realizations around a fixed point:

**Corollary 1.** Let $(M, \pi)$ be a Poisson manifold, $x_0 \in M$ a fixed point, and assume that a neighborhood $U$ of $x_0$ admits a symplectic realization $\nu : S \to U$ with the property that $\nu^{-1}(x_0)$ is simply connected and compact. Then there exists a neighborhood of $x_0$ which is integrable by a Hausdorff Lie groupoid with 1-connected $s$-fibers.

**Proof.** Note that $\nu^{-1}(x_0)$ is a Lagrangian submanifold of $S$. Therefore, $\nu^{-1}(x_0)$ is a compact, 1-connected, leaf of $\mathcal{F}^\perp(\nu)$. By Reeb stability, nearby leaves are compact, 1-connected and $\mathcal{F}^\perp(\nu)$ is simple. Hence we can apply Theorem 3. □

**Step 4: Existence of symplectic realizations**

The proof of Conn’s theorem can now be concluded by proving:

**Theorem 4.** Let $(M, \pi)$ be a Poisson manifold, $x_0 \in M$ a fixed point, and assume that the isotropy Lie algebra $\mathfrak{g}$ at $x_0$ is semi-simple of compact type, with associated simply connected Lie group $G$. Then there exists a symplectic realization $\nu : S \to U$ of some open neighborhood $U$ of $x_0$ such that $\nu^{-1}(x_0) = G$.

We first recall some of the general properties of $\Sigma(M)$ (see [6]). To construct it as a topological space and possibly as a smooth manifold (in the integrable case), we consider the Banach manifold $P(T^*M)$ consisting of paths $a : I \to T^*M$ of class $C^2$, with the topology of uniform convergence of a map together with its derivatives. Inside this Banach manifold we have the space of cotangent paths:
\[ X := \{ a \in P(T^*M) : \pi^a(a(t)) = \frac{d}{dt}p(a(t)) \}, \]
where $p : T^*M \to M$ is the bundle projection. Then $X$ is a submanifold of $P(T^*M)$ which carries a canonical foliation $\mathcal{F}$; two cotangent paths $a_0$ and $a_1$ belong to the same leaf if they are cotangent homotopic. This foliation has finite codimension and its leaf space is precisely $\Sigma(M)$. Concatenation of paths makes $\Sigma(M)$ into a topological groupoid which is smooth precisely when $M$ is integrable.

The symplectic structure on $\Sigma(M)$ is a consequence of the following general property: the restriction of the canonical symplectic form of $P(T^*M) \simeq T^*P(M)$ to $X$ has kernel $\mathcal{F}$ and is invariant under the holonomy of $\mathcal{F}$. We also conclude that any transversal to $\mathcal{F}$ carries a symplectic structure invariant under the (induced) holonomy action. Therefore, the quotient of such a transversal by the holonomy action gives a symplectic manifold, provided the quotient is smooth. Unfortunately, achieving smoothness is difficult (and it would imply integrability directly). Instead, we will perform a quotient modulo only some holonomy transformations, so that the result is smooth, and we will see that this is enough for our purposes.

**Proof.** First of all, we consider the source map $s : X \to M$ which sends a cotangent path $a(t)$ to its initial base point $p(a(0))$. This is a smooth submersion, and we look at the fiber $Y = s^{-1}(x_0)$. Since $x_0$ is a zero of $\pi$, $Y$ is saturated by leaves of $\mathcal{F}$ and we set $\mathcal{F}_Y = \mathcal{F}|_Y$. The quotient $G = Y/\mathcal{F}_Y$ is the 1-connected Lie group integrating the isotropy Lie algebra $\mathfrak{g}_{x_0}$, and so it is compact. Moreover, note that we can canonically identify $Y$ with paths in the Lie group $G$ which start at the origin, so that the quotient map $Y \to Y/\mathcal{F}_Y = G$ sends a path to its end point. Also, two points in $Y$ belong to the same leaf of $\mathcal{F}_Y$ if the corresponding paths are homotopic relative to the end points. Since the first and second homotopy groups of $G$ vanish, the leaves of $\mathcal{F}_Y$ are 1-connected fibers of a locally trivial fibration $Y \to G$ with compact base. For the local triviality, using right translations by contracting homotopies, one finds even that the restriction of our bundle to any contractible open is trivializable. By the proposition proven in the appendix, one can find:

(i) a transversal $T_X \subset X$ to the foliation $\mathcal{F}$ such that $T_Y := Y \cap T_X$ is a complete transversal to $\mathcal{F}_Y$ (i.e., intersects each leaf of $\mathcal{F}_Y$ at least once);
(ii) a retraction $r : T_X \to T_Y$;
(iii) an action of the holonomy of $\mathcal{F}_Y$ on $r : T_X \to T_Y$ along $\mathcal{F}$.

Moreover, the orbit space $S := T_X / \text{Hol}_{T_Y}(\mathcal{F}_Y)$ is a smooth (Hausdorff) manifold. Notice that the source map induces a map $\nu : S \to U$, where $U$ is an open neighborhood of $x_0$. Also, $\nu^{-1}(x_0) = Y/\mathcal{F}_Y = G$ is compact. It follows that $S$ carries a symplectic form and that $\nu : S \to U$ is a Poisson map, so it satisfies all the properties in the statement of the theorem. □
Appendix 1: A technical result on foliations

The aim of this section is to prove the proposition below which was used in the proof of Theorem 4. This proposition concerns the “transversal geometry” of a foliation of finite codimension so, in spite of being a result about foliations of Banach manifolds, it is essentially of a finite dimensional nature. We follow the approach first proposed by Haefliger [16] which consists of giving a meaning to “transversal geometry” by using the language of étale groupoids (the holonomy groupoid of the foliation restricted to a complete transversal).

**Proposition 2.** Let $\mathcal{F}$ be a foliation of finite codimension on a Banach manifold $X$ and let $Y \subset X$ be a submanifold which is saturated with respect to $\mathcal{F}$ (i.e., each leaf of $\mathcal{F}$ which hits $Y$ is contained in $Y$). Assume that:

1. **(H0)** The holonomy of $\mathcal{F}$ at all points in $Y$ is trivial.
2. **(H1)** The foliation $\mathcal{F}_Y := \mathcal{F}|_Y$ is simple; i.e., its leaves are the fibers of a submersion $p : Y \to B$ into a compact manifold $B$.
3. **(H2)** The fibration $p : Y \to B$ is locally trivial.

Then one can find:

1. **(i)** a transversal $T_X \subset X$ to the foliation $\mathcal{F}$ such that $T_Y := Y \cap T_X$ is a complete transversal to $\mathcal{F}_Y$ (i.e., intersects each leaf of $\mathcal{F}_Y$ at least once);
2. **(ii)** a retraction $r : T_X \to T_Y$;
3. **(iii)** an action of the holonomy of $\mathcal{F}_Y$ on $r : T_X \to T_Y$ along $\mathcal{F}$.

Moreover, the orbit space $T_X / \text{Hol}_{T_Y}(\mathcal{F}_Y)$ is a smooth (Hausdorff) manifold.

**Remark 2.** The proposition states that under some conditions one can lift germ-wise actions to actual actions. A similar, more familiar, situation occurs with group actions: given a discrete group $\Gamma$ and a group homomorphism from $\Gamma$ to the group of germs of diffeomorphisms of some Euclidean space $\mathbb{R}^k$, preserving the origin, one can promote this germ-wise action to an actual action of $\Gamma$ on some open neighborhood of the origin. The proposition can be seen as an instance of a more general phenomenon of this type, where one considers actions of (proper) étale groupoids instead of (finite) discrete ones. Even in the case of finite groups, although the proof is straightforward, the details are somewhat tedious.

**Remark 3.** In this proposition, by an action of the holonomy of $\mathcal{F}_Y$ on $r : T_X \to T_Y$ we mean an action of the holonomy groupoid of $\mathcal{F}_Y$ restricted to $T_Y$, denoted $\text{Hol}_{T_Y}(\mathcal{F}_Y)$, on the map $r : T_X \to T_Y$ (recall that groupoids act on smooth maps over the space of units). Also, when we say “along the leaves” we mean that the orbits of the action lie inside the leaves of $\mathcal{F}$.

In the situation described by the proposition, $\mathcal{F}_Y$ is simple and the action can be made more explicit in the following way. The action is given by a smooth
family of diffeomorphisms $h_{x,y} : r^{-1}(x) \to r^{-1}(y)$ defined for any $x, y \in T_Y$ with $p(x) = p(y)$, satisfying $h_{y,z} \circ h_{x,y} = h_{x,z}$ and $h_{x,x} = I$. Also, the action being along the leaves of $\mathcal{F}$ means that $h_{x,y}(u)$ and $u$ are in the same leaf of $\mathcal{F}$, for any $u \in r^{-1}(x)$.

Remark 4. In a preliminary version of this paper, we stated the proposition without (H0) and requiring instead in condition (H1) the leaves of $(Y, \mathcal{F}_Y)$ to be simply connected. This would be enough for this paper since the fibers of our fibration $p$ are 1-connected, a consequence of the fact that $\pi_2(G) = 0$ for any Lie group $G$. This improved version resulted from a question of Ezra Getzler, who asked if one could use the much simpler fact that $H^2(G) = 0$ (for a proof of this, see e.g. [12]). Indeed, the condition $H^2(G) = 0$ does imply (H0) for our fibration.

We now turn to the (straightforward but tedious) detailed proof of Proposition 2. We will consider cross-sections of the fibration $p : Y \to B$ whose fibers are the leaves of $\mathcal{F}_Y$. A cross-section $\sigma : U \to Y$, defined over an open set $U \subset B$, can be identified with its image $\sigma(U) \subset Y$, which is a transversal to $\mathcal{F}_Y$.

Given a cross-section $\sigma : U \to Y$, by a transversal tubular neighborhood of $\sigma$ we mean

$$
\begin{diagram}
E & \overset{\tilde{\sigma}}{\rightharpoonup} & X \\
\downarrow{r} & & \downarrow{\sigma} \\
U
\end{diagram}
$$

where $r : E \to U$ is a vector bundle and $\tilde{\sigma} : E \to X$ is an embedding defining a tubular neighborhood of $\sigma(U)$ in some transversal $T$ to $\mathcal{F}$ containing $\sigma(U)$. Hence $\tilde{\sigma}|_U = \sigma$, and $\tilde{\sigma}(E)$ is an open subset of $T$. We will assume that the vector bundle comes equipped with a norm $||\cdot||$. The proof of existence of transversal tubular neighborhoods can be found in [17]. Similarly, one can talk about a transversal partial tubular neighborhood of $\sigma$ (loc. cit. p. 109); in this case $\tilde{\sigma}$ is only defined on an open neighborhood of the zero-section in $E$. Any such transversal partial neighborhood contains a transversal tubular neighborhood (loc. cit.). By abuse of notation we write $\tilde{\sigma} : E \to T$ for a transversal partial tubular neighborhood, even if it is only defined in a open neighborhood of the zero section in $E$. Also, we have the following extension property which follows from general properties of tubular neighborhoods (see, e.g., Exercise 3, p. 118 in [17]).

Lemma 2. Let $\sigma : U \to Y$ be a cross-section and let $V$ and $W$ be opens in $U$ such that $\overline{V} \subset W \subset \overline{W} \subset U$ (where the closures are in $B$). Also let $T$ be a transversal to $\mathcal{F}$ containing $\sigma(U)$. Assume that $\tilde{\sigma}_W : E_W \to T$ is a transversal tubular neighborhood of $\sigma|_W$. Then there exists a transversal
tubular neighborhood $\tilde{\sigma} : E \to T$ of $\sigma$, defined on some vector bundle $E$ over $U$, such that $E_W|_V = E|_V$ (as vector bundles) and $\tilde{\sigma} = \tilde{\sigma}_W$ on $E|_V$.

A homotopy of two cross-sections $\sigma_0, \sigma_1 : U \to Y$, defined over the same open set $U \subset B$, is a smooth family $\{\sigma_t : t \in [0,1]\}$ of cross-sections over $U$ connecting $\sigma_0$ and $\sigma_1$. Since the fibration $p : Y \to B$ is locally trivial with connected fibers, it follows that any two cross-sections over a small enough contractible open set are homotopic.

Let $\sigma = \{\sigma_t\}$ be a homotopy between two cross-sections $\sigma_0, \sigma_1 : U \to Y$. Two transversal partial tubular neighborhoods $\tilde{\sigma}_i : E \to X$ of $\sigma_i$ ($i \in \{0,1\}$) are said to be $\sigma$-compatible if the map

$$\tilde{\sigma}_0(e) \mapsto h \tilde{\sigma}_1(e)$$

(defined for $e \in E$ in the intersection of the domains of $\tilde{\sigma}_i$) has the following properties:

(a) $x$ and $h(x)$ are in the same leaf of $F$ for all $x$;
(b) the germ of $h$ at each point $\sigma_0(u)$, where $u \in U$, coincides with the holonomy germ of the foliation $F$ along the path $t \mapsto \sigma_t(u)$.

**Lemma 3.** Let $\sigma_0, \sigma_1 : U \to Y$ be two cross-sections over an open $U \subset B$ connected by a homotopy $\sigma = \{\sigma_t\}$. Let $\tilde{\sigma}_0 : E \to X$ be a transversal partial tubular neighborhood above $\sigma_0$ and let $T$ be a transversal to $F$ containing $\sigma_1(U)$. Then, for any $V \subset B$ open with $\overline{V} \subset U$, there exists

(i) an open subset $F \subset E|_V$ containing $V$ (hence $\tilde{\sigma}_0|_F$ is a transversal partial tubular neighborhood of $\sigma_0|_V$);
(ii) a transversal partial tubular neighborhood $\tilde{\sigma}_1 : F \to T$ of $\sigma_1|_V$,

such that $\tilde{\sigma}_0|_F$ and $\tilde{\sigma}_1$ are $\sigma|_V = \{\sigma_t|_V\}$-compatible.

**Proof.** Fix $\sigma_0, \sigma_1, \tilde{\sigma}_0 : E \to X$ and $T$ as in the statement. As a temporary terminology, we say that an open subset $V \subset U$ is good if $\overline{V} \subset U$ and the conclusion of the lemma holds for $V$. An open subset of a good open set is also good.

We first show that any $u \in U$ admits a good open neighborhood. Consider the holonomy transformation along the path $\sigma^u(t) := \sigma(t, u)$ from the transversal $\tilde{\sigma}_0(E)$ to the transversal $T$. This is the germ of a diffeomorphism $h_u$, defined in some neighborhood of $\sigma_0(u)$, which can be taken of the form $\tilde{\sigma}_0(F)$ for some open set $F \subset E$ containing $u$. Choosing $F$ a small enough open ball (relative to $|| ||$) and setting $\tilde{\sigma}_1 := h_u \circ \tilde{\sigma}_0|_F$, we conclude that $V$ is a good open set.

Let $V$ be an arbitrary open set with $\overline{V} \subset U$. We can find a cover of $\overline{V}$ by good open sets, so we can extract a finite subcover $\{U_i : 1 \leq i \leq p\}$ of $\overline{V}$ in which each $U_i$ is good. We prove by induction on $p$ that $V$ must be a good
open set. The result clearly holds if \( p = 1 \). For the induction step, assume
the assertion is true for \( p - 1 \) and assume that \( \mathcal{V} \) is covered by \( p \) good open
sets \( U_1 \subset U \). Choose another cover \( \{ V_i \} \) of \( V \) with \( \mathcal{V}_i \subset U_i \). Then, by
the induction hypothesis, \( U_1 = V_1 \) and \( U_2 := V_2 \cup \cdots \cup V_p \) will be good open sets.
Moreover, \( \mathcal{V} \subset U_1 \cup U_2 \), so all that remains to show is the case \( p = 2 \).

Let \( U_1, U_2 \subset U \) be good open sets and \( \mathcal{V} \subset U_1 \cup U_2 \subset U \). We need to
show that \( V \) is a good open set. Let \( F_i \subset E \), \( \tilde{\sigma}_i : F_i \to T \) be the associated
transversal partial tubular neighborhoods. Consider also the induced maps
\( h_i : \tilde{\sigma}_0(F_i) \to \tilde{\sigma}_i(F_i) \). We consider two new open sets \( V_i \) such that \( \mathcal{V} \subset V_1 \cup V_2 \)
and \( \mathcal{V}_i \subset U_i \). Compactness of \( \mathcal{V}_i \) implies that we can find \( R > 0 \) such that:
\[
x \in E|V_i, ||x|| < R \implies x \in F_i.
\]
Due to the properties of \( h_i \) (properties (a) and (b) above), we see that \( h_1 \) and
\( h_2 \) coincide in a neighborhood of \( \sigma_0(u) \) in \( \sigma_0(U) \). Hence, choosing eventually
a smaller \( R \), we may assume that
\[
x \in E|V_1 \cap V_2, ||x|| < R \implies \tilde{\sigma}_1(x) = \tilde{\sigma}_2(x).
\]
It follows that \( \tilde{\sigma}_1 \) and \( \tilde{\sigma}_2 \) will glue on
\[
F = \{ x \in E_{V_1 \cup V_2} : ||x|| < R \}
\]
and the resulting transversal partial tubular neighborhood will have the desired
properties. Hence \( V \) is a good open set. \( \square \)

For the next lemma, we introduce the following notation. An \( \mathcal{F} \)-data is a
tuple
\[
(2) \quad \{ U_i, \sigma_i, \tilde{\sigma}_i, \sigma_{(i,j)}, E : 1 \leq i, j \leq k \}
\]
consisting of the following:
(a) \( \{ U_i : i = 1, \ldots, k \} \) is a family of open sets in \( B \) and \( E \) is a vector bundle
over \( U = U_1 \cup \cdots \cup U_k \).
(b) \( \sigma_i : U_i \to Y \) are cross-sections and \( \sigma_{(i,j)} \) are homotopies between \( \sigma_i|U_i \cap U_j \)
and \( \sigma_j|U_i \cap U_j \).
(c) \( \tilde{\sigma}_i : E|U_i \to X \) are transversal tubular neighborhoods over \( \sigma_i \) such that the
restrictions of \( \tilde{\sigma}_i \) and \( \tilde{\sigma}_j \) to \( E|U_i \cap U_j \) are \( \sigma_{i,j} \)-compatible for all \( i \) and \( j \).

Assume now that:
(i) \( U_{k+1} \subset B \) is another open set, \( \sigma_{k+1} : U_{k+1} \to Y \) is a cross-section above
\( U_{k+1} \) and \( T \) is a transversal to \( \mathcal{F} \) containing \( \sigma_{k+1}(U_{k+1}) \).
(ii) For each \( 1 \leq i \leq k \) we have a homotopy \( \sigma_{(i,k+1)} \) between \( \sigma_i|U_i \cap U_{k+1} \)
and \( \sigma_{k+1}|U_i \cap U_{k+1} \).
Let \( V_i \subset B \) be open sets with
\[
\mathcal{V}_i \subset U_i \quad (1 \leq i \leq k+1)
\]
and set \( V = V_1 \cup \cdots V_k \), \( V' = V \cup V_{k+1} \). Then:
Lemma 4. Under the above assumptions, there is a vector bundle $E'$ over $V'$ together with an embedding $\phi : E'|_V \hookrightarrow E|_V$ of bundles, as well as a map $\tilde{\sigma}_{k+1} : E'|_{V_{k+1}} \to X$ which is a transversal tubular neighborhood of $\sigma_{k+1}|_{V_{k+1}}$ inside $T$ such that

$$\{V_i, \sigma, \tilde{\sigma} \circ \phi, \sigma_{(i,j)}|_{V_i \cap V_j}, E' : 1 \leq i, j \leq k + 1\}$$

is an $F$-data.

Proof. For $1 \leq i \leq k + 1$, choose open sets $\nabla_i \subset V'_i \subset \nabla'_i \subset U_i$. We can apply Lemma 3 to:

- the restrictions of $\sigma_i$ and $\sigma_{k+1}$ to $U_i \cap U_{k+1}$ and the homotopy $\sigma_{(i,k+1)}$;
- the transversal tubular neighborhood to $\sigma_i|U_i \cap U_{k+1}$ which is the restriction of $\tilde{\sigma}_i$ to $E|U_i \cap U_{k+1}$;
- the open set $V'_i \cap V'_{k+1}$ whose closure is inside $U_i \cap U_{k+1}$.

This gives a transversal tubular neighborhood of $\sigma_{k+1}|_{V'_i \cap V'_{k+1}}$, denoted

$$\tilde{\sigma}_{k+1}^{(i)} : E'_{i,k+1} \to T$$

defined on some $E'_{i,k+1} \subset E|_{V'_i \cap V'_{k+1}}$, an open set containing $V'_i \cap V'_{k+1}$.

Now choose open sets $\nabla_i \subset V''_i \subset \nabla''_i \subset V'_i$. Since the closure of $V''_i \cap V''_{k+1}$ is compact, we find $R_i > 0$ such that

$$x \in E|_{V''_i \cap V''_{k+1}}, ||x|| < R_i \implies x \in E'_{i,k+1}.$$

Next, for each $1 \leq i, j \leq k$, the restrictions of $\tilde{\sigma}_{k+1}^{(i)}$ and $\tilde{\sigma}_{k+1}^{(j)}$ to $E'_{i,k+1} \cap E'_{j,k+1}$ are transversal partial tubular neighborhoods above the same cross-section $\sigma_{k+1}|_{V'_i \cap V'_j}$. Moreover, they are $\sigma$-compatible, where $\sigma$ is the concatenation of the homotopies $\sigma_{(i,k+1)}$, $\sigma_{(j,i)}$ and $\sigma_{(k+1,1)}$. Since all paths $\sigma^u (\cdot) = \sigma(u, \cdot)$ induced by the homotopy $\sigma$ are inside leaves of $F_Y$ and the holonomy of $F$ along loops inside $Y$ is trivial (the first assumption in the statement), the holonomy germs induced by the closed loops $\sigma^u_{(k+1,j)} \circ \sigma^u_{(j,i)} \circ \sigma^u_{(i,k+1)}$ are trivial. We conclude that

$$\{x \in E'_{i,k+1} \cap E'_{j,k+1} : \tilde{\sigma}_{k+1}^{(i)}(x) = \tilde{\sigma}_{k+1}^{(j)}(x)\}$$

contains an open subset in $E'_{i,k+1} \cap E'_{j,k+1}$ containing $V'_i \cap V'_j \cap V'_{k+1}$. Again, we can find constants $R_{i,j}$ such that

$$x \in E'_{i,k+1}|_V \cap V''_j \cap V''_{k+1}|_V \cap E'_{j,k+1}|_V \cap V''_i \cap V''_{k+1}|_V, ||x|| < R_{i,j} \implies \tilde{\sigma}_{k+1}^{(i)}(x) = \tilde{\sigma}_{k+1}^{(j)}(x).$$

Let us set

$$R = \min\{R_i, R_{i,j} : 1 \leq i, j \leq k\}, \quad E'' = \{x \in E : ||x|| < R\}.$$
The maps $\tilde{\sigma}_{k+1}^i$ glue together to give a smooth map defined on $E^\prime\prime|_{V''\cap V''_{k+1}}$ where

$$V'' = V''_1 \cup \cdots \cup V''_k.$$ 

Denote this map by $\tilde{\sigma}_{k+1}''$. Consider now $\lambda : [0, \infty) \to [0, 1)$ to be a diffeomorphism equal to the identity near 0 and define the embedding

$$\phi : E \to E^\prime\prime, h(x) = R^{\frac{\lambda(||x||)}{||x||}}x.$$ 

Composing the last two maps, we obtain $\tilde{\sigma}_{k+1}'' : E|_{V''_{k+1}\cap V''} \to T$ which is a transversal tubular neighborhood of $\sigma_{k+1}|_{V''_{k+1}\cap V''}$. We can now apply Lemma 2 to find:

1. a vector bundle $E_{k+1}$ over $V_{k+1}$ such that $E_{k+1}|_{V_{k+1}\cap V} = E|_{V_{k+1}\cap V}$;
2. a transversal tubular neighborhood $\tilde{\sigma}_{k+1}'$ of $\sigma_{k+1}|_{V_{k+1}}$ which is defined on the entire $E_{k+1}$ and which coincides with $\tilde{\sigma}_{k+1}''$ on $E|_{V_{k+1}\cap V}$.

Finally, if we let $E'$ be the vector bundle over $V' = V \cup V_{k+1}$ obtained by gluing $E|_V$ (over $V$) and $E_{k+1}$ (over $V_{k+1}$), we have obtained the desired $F$-data.

Proof of Proposition 2. Let $U^{(1)} = \{U^{(1)}_1, \ldots, U^{(1)}_n\}$ be a finite good cover of $B$ in the sense of [2]. Since $B$ is compact, good covers exist; actually, any cover can be refined by a finite good cover (see loc. cit.). Hence, refining covers consisting of opens over which $p : Y \to B$ is trivial, we may assume that there are cross-sections $\sigma_i : U^{(1)}_i \to Y$, where the image of each $\sigma_i$ is inside some transversal $T_i$ of $F$. Since all intersections $U^{(1)}_i \cap U^{(1)}_j$ are contractible and the fibers of $p : Y \to B$ are connected, there are homotopies $\sigma_{(i,j)}$ between $\sigma_i|_{U_i \cap U_j}$ and $\sigma_j|_{U_i \cap U_j}$. Finally, we choose new good covers $U^{(k)} = \{U^{(k)}_1, \ldots, U^{(k)}_n\}$, $k = 1, \ldots, n$, with the property

$$\overline{U^{(k+1)}_i} \subset U^{(k)}_i \quad (i, k = 1, \ldots, n).$$ 

We then apply Lemma 4 inductively: at each step one gets a vector bundle over $U^{(k)}_1 \cup \cdots \cup U^{(k)}_n$ and an $F$-data. For $k = n$, we obtain a vector bundle over $B$, a complete transversal to $F_Y$ (the images of the $U^{(n)}_i$'s by the cross sections) and the transversal to $F$ (the transversal tubular neighborhoods of the final $F$-data).

It remains only to show that $T_X/H\text{ol}_T_Y(F_Y)$ is a Hausdorff manifold. This can be checked directly (for instance, if the starting transversals $T_i$ are chosen so that their closures are disjoint, then the quotient is just the resulting vector bundle $E$ over $B$). Here we indicate a more conceptual argument which is based on general properties of groupoids and their representations (in the sense of spaces on which the groupoids act). For Morita equivalences, we
refer to [19]. First of all, representations can be transported along Morita
equivalences and, provided the groupoids and the Morita equivalences used
are Hausdorff, the Hausdorff property of representations is preserved by this
transport. Secondly, since $\mathcal{F}_Y$ is induced by the submersion $p : Y \to B$, the
groupoid $\text{Hol}_{T_Y}(\mathcal{F}_Y) \Rightarrow T_Y$ is Morita equivalent to the trivial groupoid $B \rightrightarrows B$,
via the bimodule $T_Y \xleftarrow{\text{id}} \xrightarrow{p} B$. Finally, one just remarks that under this
equivalence, $T_X / \text{Hol}_{T_Y}(\mathcal{F}_Y)$ is the representation of $B \rightrightarrows B$ which corresponds
to the representation $T_X$ of $\text{Hol}_{T_Y}(\mathcal{F}_Y)$. \hfill \square

Appendix 2: Historical remarks

The study of the linearization problem for Poisson brackets was initiated
by Alan Weinstein in the foundational paper [23]. There, he states the problem
and shows that the formal linearization problem can be reduced to a cohomol-
ogy obstruction. If the isotropy Lie algebra is semisimple, this obstruction
vanishes. For analytic linearization he conjectured that, provided the isotropy
Lie algebra is semisimple, this can always be achieved, a result later proved by
Conn [3].

In [23], Alan Weinstein also considers the smooth linearization prob-
lem. He gives an example of a smooth, nonlinearizable, Poisson bracket with
isotropy Lie algebra $\mathfrak{sl}(2,\mathbb{R})$. The situation is remarkably similar to the case of
Lie algebra actions, and this counter-example is analogous to the example of
a nonlinearizable smooth action of $\mathfrak{sl}(2,\mathbb{R})$, given by Guillemin and Sternberg
in [15]. By contrast, he suggests that linearization when the isotropy is
could be proved as follows (see [23, p. 539]):

The first step would be to use the theorems of Reeb and Moussu
to “linearize” the foliation by symplectic areas. Next, a “volume
preserving Morse lemma” would be used to put in standard form
the function which measures the symplectic area of the leaves.
Finally, the deformation method of Moser and Weinstein
would have to be applied to each symplectic leaf, with care taken to
assure regularity at the origin.

The proof sketched was actually implemented by Dazord in [9]; it is less known
that this result and a proof of it can be traced back to the thesis of Reeb [21]
(but in the dual language of completely integrable Pfaffian forms, which, in
dimension 3, correspond to bivectors which are Poisson). Weinstein goes on to
conjecture that smooth linearization can be achieved for compact semisimple
isotropy. This, again, was proved to be so by Conn in [4].

Conn’s proof of smooth linearization is a highly nontrivial analytic argu-
ment. He views the effect of changes of coordinates upon the Poisson tensor as
a nonlinear partial differential operator. A combination of Newton’s method
with smoothing operators, as devised by J. Nash and J. Moser, is used to construct successive approximations to the desired linearizing coordinates. The linearized equations that need to be solved at each step are nondegenerate and overdetermined (the operator differentiates only along the symplectic foliation). However, by working at the level of Lie algebra cohomology of \( \mathfrak{g} \) with coefficients in the space of smooth functions on \( \mathfrak{g}^* \), Conn is able to find accurate solutions to the linearized equations. This involves many estimates on the Sobolev norms, which are defined from the Killing form, and so take advantage of its invariance, nondegeneracy and definiteness.

After Conn’s work was completed, attention turned to other Lie algebras. In [24], Weinstein showed that semisimple Lie algebras of real rank greater than one are nonlinearizable, in general. The case of real rank 1, with the exception of \( \mathfrak{sl}(2, \mathbb{R}) \), remains open. In [10], Dufour studied linearization when the isotropy belongs to a certain class of Lie algebras, called nonresonant, which allowed him to classify all the 3-dimensional Lie algebras that entail linearizability. Dufour and Zung proved formal and analytic linearization for the Lie algebra of affine transformations \( \mathfrak{aff}(n) \) [11]. There are also examples of Poisson structures for which linearization can be decided only from knowledge of its higher order jets (see [1]). More recently, a Levi decomposition for Poisson brackets, generalizing linearization, has been introduced by Wade ([22], formal category), Zung ([27], analytic category), and Zung and Monnier ([20], smooth category). The methods are very similar to the ones of Weinstein and Conn. A survey of these results can be found in [13].

In spite of Conn’s master work, the question remained if a simple, more geometric proof of smooth linearization would be possible. In the introduction of [25], Alan Weinstein writes:

*Why is it so hard to prove the linearizability of Poisson structures with semisimple linear part? Conn published proofs about 15 years ago in a pair of papers full of elaborate estimates (…) no simplification of Conn’s proofs has appeared.*

*This is a mystery to me, because analogous theorems about linearizability of actions of semisimple groups near their fixed points were proven (…) using a simple averaging.*

In this paper he goes on to propose to use Lie algebroid/groupoid theory to tackle this and other linearization problems. After this work, it become clear that this would indeed be the proper setup for a geometric proof of linearization. However, his attempt would not be successful because some of the techniques needed were not available yet. Some basic results on proper groupoids, as well as a full understanding of the integrability problem for Poisson manifolds and Lie algebroids was missing, and this was done later by us in [5], [6], [7].
In the end, the geometric proof we have given here is really a combination of classical results on Lie groups extended to the groupoid context. Once the groupoid is brought into the picture, one has the usual differential geometric machinery at hand, and hence also all the standard techniques to deal with linearization problems one finds in different contexts (Moser trick, Van Est argument, Reeb stability, averaging). It is curious that the methods used are so close to the proof suggested by Alan Weinstein for the case of $\mathfrak{so}(3)$, that we have quoted above. A general setup to discuss linearization problems and their relation to deformation problems will be given elsewhere (work in progress).

Finally, note that it would be possible to combine our Proposition 1 with the linearization theorem for proper groupoids around fixed points (see [26], [28]) to obtain another proof of Conn’s theorem (this would be a geometric-analytic proof, since the linearization of proper groupoids also involves some estimates.)
