INTRODUCTION
Hypercholesterolemia is one of the leading causes of death in the developed countries. It is a chronic progressive disease which commonly predisposes to various ailments such as coronary artery disease, myocardial infarction and cerebrovascular disease [1, 2].

The relationship between hypercholesterolemia and cardiovascular mortality has been known for decades. Hypercholesterolemia which is a risk factor in the progression of atherosclerosis is characterized by an increase in the levels of low-density lipoprotein cholesterol (LDL-c), very low-density lipoprotein cholesterol (VLDL-c) and a decrease in high-density lipoprotein cholesterol (HDL-c) [3]. Moreover, several experimental studies have demonstrated that, in addition to its well-known proatherogenic effect in the vasculature, hypercholesterolemia may directly affect the heart causing contractile dysfunction [4].

Accumulating evidence has shown that reactive oxygen species (ROS) generated during hypercholesterolemia are involved in key processes in the development and progression of atherosclerosis, including endothelial dysfunction and oxidative modification of low-density lipoprotein [5]. In general, lipid metabolism imbalance results from the interaction between genetics and environmental factors, such as eating habits, especially high lipid consumption. Therefore, diet lipid content has been investigated as a key factor in preventing cardiovascular disease, including hypercholesterolemia. Experimental studies with high-fat diets have used very high contents of dietary fat, in short-period protocols, without finding serum lipid impairment. On the other hand, lipid structure, composition, configuration, in addition to excessive fat and cholesterol consumption are also believed to affect the lipid profile in the plasma.

Several studies were investigated, inducing hypercholesterolemia in rats is often through a high fat, high cholesterol diet, with the fat source varying from lard, coconut, soybean or palm oil only or in association with other factors [6]. Therefore, it was of great interest to understand the antioxidant activity of A. digitata aqueous extract on hypercholesterolemia. The present study was designed to evaluate the antihypercholesterolemic and anti-atherosclerotic effects of the aqueous extract of Adansonia digitata in rats.

MATERIALS AND METHODS

Chemicals and reagents

Cholesterol, highly Purified obtained from Calbiochem 1-800-222-0342 (U. S. and Canada); 2,2-diphenyl-1-picrylhydrazyl radical-scavenging (DPPH); Folin-Ciocalteu reagent (Sigma chemical Co., St.

ABSTRACT

Objective: Poor control of hypercholesterolemia which mediated by overproduction of reactive oxygen species and endothelial dysfunction leads to atherosclerosis. The present study aimed to investigate the antihypercholesterolemic and anti-atherogenic effects of Adansonia digitata (AD) in heated palm oil/cholesterol supplemented with egg yolk in rat.

Methods: Quantitative phytochemical screening of aqueous extract of A. digitata was carried out to identify the phytoconstituents. In vitro and in vivo antioxidant potential was evaluated. The antihypercholesterolemic and anti-atherosclerosis activity of A. digitata was evaluated by inducing hypercholesterolemia in rats with heated palm oil/cholesterol diet supplemented with egg yolk for 10 w. At the end of the induction period, animals were divided into 5 groups of 8 rats each after 6 w of induction: Group I (normocholesterolemic rat, NCR), Group II (hypercholesterolemia rat, HCR), Group III (Atorvastatin 2 mg/kg), Groups IV (AD. 100 mg/kg) and V (AD. 200 mg/kg). Hemodynamic parameters, lipid profile, atherogenic indices and oxidative stress markers were evaluated.

Results: Adansonia digitata significantly reduced the systolic arterial blood pressure (SBP), diastolic arterial blood pressure (DBP), pulsatile pressure (PP) and heart rate compared to the hypercholesterolemic group. Plant extract reveal important flavonoids and phenolic contents and has high-density lipoprotein cholesterol (HDL-c) [3]. Moreover, several studies were investigated, inducing hypercholesterolemia in rats is often through a high fat, high cholesterol diet, with the fat source varying from lard, coconut, soybean or palm oil only or in associated [6]. Therefore, it was of great interest to understand the antioxidant activity of A. digitata aqueous extract on hypercholesterolemia. The present study was designed to evaluate the antihypercholesterolemic and anti-atherosclerotic effects of the aqueous extract stem bark of A. digitata in rats.

Conclusion: The aqueous extract of A. digitata possessed antihypercholesterolemic and anti-atherogenic effects via modulation overproduction of reactive oxygen species and endothelial dysfunction.

Keywords: Adansonia digitata, Lipid profile, Antioxidant potential, Atherogenic indices
Louis, Mo); 2,4,6-tripryridyl-triazine (TPTZ) and Ferric ion Reducing Antioxidant Parameter (FRAP) obtained from Sigma (U. S.). All other chemicals and reagents used, including (catechin, aluminium chloride, potassium acetate, acetate buffer, chloroform, glacial acetic acid, urethane) in the present study were obtained commercially and were of analytical grade.

Animals

The antihypercholesterolemic activity was carried out on fifty healthy male albino Wistar rats aged 6-8 w and weighing 180-200 g prior to the experiment. Animals were housed in standard environmental conditions under a 12/12 h light/dark natural cycle in the animal house of the Laboratory of Animal Physiology of the University of Yaoundé I. Animals had free access to standard diet and tap water ad libitum. All animals treatment procedures used in the present study were approved by the Cameroon National Ethical Committee (Ref. N° FWIRB 00001954).

Source and preparation of diets

Commercially purchased palm oil local used was five-times-heated, according to the modified method as described by Owu et al. [7-9]. Briefly, 2.5 L of palm oil was heated in a metal wok at 150 °C for 10 min. To prepare five-tim-es-heated oil, the whole heating process was repeated four more times with a fresh batch and five hours cooling interval. No fresh oil was added between batches to replace oil absorbed by the heating. The test diets were formulated by mixing 15% (w/w) of five-heated palm oil with ground 0.5 % cholesterol diet supplemented with egg yolk.

Preparation of the aqueous extract

Samples of A. digitata were collected in the town of Maroua, Dàmaré, Far North Region (Cameroon), in November 2017. A sample was dried, authenticated, and stored (Cameroon National Herbarium Specimen No42417/HNC, Yaoundé). The stem bark peels were air-dried at room temperature to avoid possible degradation or denaturation of their putative compounds. The air-dried stem bark of A. digitata was blended to powder using an electric blender and stored in a glass container. About 100 g of the powder stem materials were extracted with 1000 ml of distilled water for 24 h. The macerate obtained was filtered using a Wattman No. 3 paper then, the resultant extract was dried in the oven at 45 °C. A solid mass of the aqueous stem bark extract was obtained and stored at 4 °C until use.

Quantitative estimation of phytoconstituents

The quantitative phytochemical screening of aqueous extract of stem bark of A. digitata was carried out to determine total phenolic and total flavonoids content using standard test.

Determination of polyphenolic concentration

The polyphenolic contents in the extract were measured using the Folin-Ciocalteu reagent (Sigma chemical Co., St. Louis, Mo), according to the method of Gabriel et al. [10]. Plant extract (60 μl) was mixed with 2 ml of Folin-Ciocalteu reagent diluted 10 times for the determination of free polyphenolic content. The extract concentrations were from 0.05 to 4 mg/ml (seven different concentrations). The absorbance was read at 750 nm after 30 min using a spectrophotometer (UV-Shimadzu). Catechin (Sigma) was used as standard and each concentration was replicated three times. The catechin concentrations were from 10 to 200 μg/ml.

Total flavonoids content

The aluminum chloride colorimetric method was used to determine the flavonoid content of plant extracts. 0.5 mg/ml of extract solution was added into 1.5 ml of methanol 0.1 ml of 10 % aluminium chloride was added followed by incubation for 5 min after which 0.1 ml potassium acetate (1 M). Finally, 2.8 ml distilled water was added and shaken and kept at room temperature for 30 min. Absorbance of the sample was noted at 420 nm with UV spectrophotometer. Quercetin was used as the standard for the calibration curve. Flavonoid contents were expressed as mg/g quercetin equivalent dry weight. A yellow color indicated the presence of flavonoids.

From the standard graph, the amount of total flavonoids content in the sample as per absorbance values was calculated and expressed as quercetin equivalents (mg/g).

In vitro antioxidant activity

A. digitata antioxidant activity was assessed using different assays in vitro: 2,2-diphenyl-1-picrylhydrazyl radical-scavenging (DPPH) and Ferric ion Reducing Antioxidant Parameter (FRAP). Each test was done with three replicates.

DPPH radical scavenging activity

The hydrogen-donating ability of each extract was examined according to the method previously described by Bender et al. [11] in the presence of a DPPH stable radical. Gallic acid at various concentrations (5-200 μg/ml) was used as standard. The antioxidant activity was calculated as % inhibition using the formula:

\[
\% \text{inhibition} = \left( \frac{A_{\text{blank}} - A_{\text{sample}}}{A_{\text{blank}}} \right) \times 100
\]

A blank = absorbance of the control
A sample = absorbance in the presence of the extract.

The EC_{50} value (mg/ml), the effective concentration at which the DPPH radicals were scavenged by 50 % was calculated with the equation from the curve. Gallic acid was used as positive control.

Antioxidant potential by ferric reducing antioxidant power (FRAP)

Extract antioxidant activity was measured by FRAP assay as described previously by Apak et al. [12]. Briefly, ferric ferrous ion reduction at low pH forms a colored ferrous-2,4,6-tri (2-pyridyl)-s-triazine complex. Two milliliters (2.0 ml) of FRAP reagent, containing 2,4,6-tripryridyl-triazine (TPTZ) 10.0 mmol, FeCl_{3} (10.0 mmol) and acetate buffer (300 mmol; pH = 3.6) was mixed with 75 μL of extract or solvent (blank) to evaluate the free antioxidant capacity. The absorbance was read at 593 nm after 12 min of incubation. Catechin was used for calibration from 0.05 to 4.0 μg/ml as the extract.

Estimation of iodine and peroxide values of palm oil

The iodine/peroxide value of oil was determined according to the American Oil Chemists Society (AOCS) standard titration method [13].

Study design

The rats (n = 60) were allowed to acclimatize for 1 w prior to treatment. They were randomly divided into two groups. The first group made of 10 rats received basal diet (control) and the second group of 36 rats was received a basal diet fortified with 0.5 % cholesterol, 15 % heated palm oil (HPO) and egg yolk, for 6 w. After 6 w, control was maintained and the hypercholesterolemic group was further divided into the following four groups of 8 rats each: control negative receiving distilled water (10 ml/kg by oral gavage) and 3 groups receiving by oral gavage aqueous extract of A. digitata [at the doses of 100 and 200 mg/kg] or standard atorvastatin (10 mg/kg, p. o.), respectively. Atorvastatin or aqueous extract in the vehicle was administered daily by oral gavage for the last 4 w of the study. The mean body weight and food intake were taken weekly during the study period.

Hemodynamic parameters recording

At the end of the investigation period, the blood pressure and heart rate of all rats were recorded. Briefly, each rat was anesthetized using an intraperitoneal injection of urethane (1.5 g/kg). The trachea was exposed and cannulated to facilitate spontaneous breathing. The arterial blood pressure and heart rate were measured from the right carotid artery via an arterial cannula connected to a pressure transducer coupled with a hemodynamic recorder Biopac Student Lab. (MP35) and computer. Thirty minutes of equilibration period were observed before each measure.

Blood and organs collection

Immediately after hemodynamic parameters recording, blood samples were collected from the abdominal artery and centrifuged at 3000 rpm for 15 min. The plasma obtained was kept at-20 °C for...
biochemical analysis. Thereafter, the heart, kidney, liver, and thoracic aorta were collected, washed in saline, weighed, and kept for assessment of oxidative stress markers.

**Biochemical analysis**

The Mc Elven solution was used to homogenize the heart and aorta while a Tris-HCl (50 mmol) buffer solution was used for the liver and kidney (20%, w/v). Each homogenate was centrifuged at 3000 rpm for 25 min and stored at -20 °C. Tissue protein concentration was assayed according to Gornall et al. [14, 15] using the biuret reagent (CALBIOCHEM, Germany). Malondialdehyde (MDA) was determined using the procedure of Wilks et al. [16], whereas reduced glutathione (GSH) was determined using the method described by Ellman [17]. The serum concentrations of total cholesterol (TC), high-density lipoprotein cholesterol (HDL-c), and triglycerides (TG) were determined using commercial diagnostic kits (CALBIOCHEM, Germany).

**Cardiovascular indices**

Atherogenic indices (AIP), cardiac risk ratio (CRR) and cardioprotective index (CPI) were calculated by using the values of lipid profile parameters in the following way Niroumand et al. [18]:

\[ \text{AIP} = \log\left(\frac{\text{Triglycerides}}{\text{HDL} - c}\right) \]

\[ \text{CRR} = \frac{\text{Total cholesterol}}{\text{HDL} - c} \]

\[ \text{CPI} = \frac{\text{HDL} - c}{\text{LDL} - c} \]

**Histopathological analysis**

The aorta tissues samples were removed and preserved in 10% buffered formaldehyde and then processed, embedded in paraffin and sectioned (4 µm) as previously reported [19]. Cross abdominal aorta section was stained with hematoxylin-eosin and periodic acid-Schiff stain. The morphological study was done by a pathologist in blinded randomized sections of the tissues, with light microscopy and using the most appropriate stain for each lesion.

**Statistical analysis**

The results were analyzed using GraphPad Prism software version 8.0.1 and expressed as mean±standard error of mean (SEM). The analysis of variance (ANOVA) was done for batch comparison. The Tukey post-test was applied to determine the difference between batches in case the ANOVA test was significant at p < 0.05.

**RESULTS**

**Total phenolic and flavonoid contents**

The phenolic and flavonoid contents of A. digitata were determined and values are shown in Table 1. The aqueous extract of A. digitata was found containing a significant amount of phenols and flavonoids as demonstrated by its total phenolic and flavonoid contents, with respective values of 666.08±14.95 mg/g catechin equivalents (EC/g) and 116.54±3.33 mg/g quercetin equivalents (QUE/g).

**FRAP assay**

Table 1 shows the reductive capacities of the aqueous extract of A. digitata. The present of the reducers in plant extract causes the reduction of F3+/ferricyanide complex to the ferrous form. The FRAP assay was expressed as catechin equivalent (EC) in mg/g of samples used (y = 0.0632x+0.2084; R² = 0.9986). The FRAP of aqueous extract of the A. digitata was 178.66±1.24 catechin equivalent (mg/g).

**Free radical scavenging assay (DPPH)**

The results expressed as a percentage of anti-radical activity (table 1) reveal that the aqueous extract of A. digitata tested exhibits inhibitory activity opposite the radical DPPH, with 60.37±0.52 % compared to the standard for a maximum concentration of 100 µ/mL. IC50 for DPPH radical-scavenging activity was 60.8 µg/mL, the aqueous extract of A. digitata has moderate antioxidant power, it was relatively less potent than gallic acid whose value was in the order of 2.95 µg/mL.

**Iodine and peroxide values**

The results investigated to determine the degree of unsaturation in palm oil show a highly significant increase in iodine and peroxide values of heated palm oil (558.36±8.97 mg/g and 56.33±1.64 mEqO₂/kg), respectively compared with fresh oil (5.34±0.12 mEqO₂/kg). The lower iodine value signifies low degree of unsaturation and the lesser the liability of the oil to become rancid by oxidation (table 1).

**Table 1: Antioxidant activity, total phenols and total flavonoid of A. digitata extract**

| Samples                | Parameters       | Values         |
|------------------------|------------------|----------------|
| A. digitata            | DPPH (%)         | 60.37±0.52     |
|                        | DPPH (IC₅₀ µg/ml) | 60.8           |
|                        | FRAP (mg EC/g MS) | 178.66±1.24    |
|                        | Total phenolic content (mg EQ/g MS) | 666.08±14.95 |
|                        | Total flavonoid content (mg EQ/g MS) | 116.54±3.33 |
| Palm oil               | Iodine index (mg/g) | 558.36±8.97   |
|                        | Peroxide index (mEqO₂/kg) | 56.33±1.64   |

Data are expressed as mean±SEM (n = 3) and analyzed by one-way ANOVA followed by the Tukey post-test.

**Bodyweight and food intake**

Comparison of the weight gain (fig. 1a) showed that at the end of the experimental period on the 42th day of the experiment induced, an aqueous extract of A. digitata 111 hypercholesterolemic rats had higher (P <0.001) weight gain than the control group (fig. 1a). The difference between the control and the hypercholesterolemic groups started to become pronounced from the two weeks until the end week of the experiment. After 42rd day of the experiment induced, an aqueous extract of A. digitata applied together with the hypercholesterolemic moderately reduced weight gain of the experimental animals significant. Additionally, there was no significant difference also, in the weekly intragastric application of the combination of the food intake in all study groups compared to the control (fig. 1b).

---

**Fig. 1: Effect of aqueous extract of A. digitata or atorvastatin on body weight (a) and food intake in rat fed a HPOC diet supplemented with egg yolk. Data are expressed as mean±SEM (n=6) and analyzed by one-way ANOVA followed by the Tukey post-test. p<0.05, bp<0.01, ap<0.001 versus HCR group; NCR: Normcholesterolemic rat; HCR: Hypercholesterolemic rat; AD: Adansonia digitata; Ator: Atorvastatin**
Effect of aqueous extract of *A. digitata* on the blood pressure and heart rate

After 10 w of the administration, the hypercholesterolemic group showed a significant increase of 22.68 %, 11.76 % and 47.32 % (P<0.001) in SBP; DBP and PP respectively as compared to the control group. *A. digitata* at different doses caused a significant reduction in SBP, DBP and PP relative to the hypercholesterolemic group. The dose of 100 and 200 mg/kg produced (10.51 % and 25.91 %, P<0.001) a reduction in SBP (2.85 % and 21.88 %, P<0.001), DBP and (23.59 % and 32.81 %, P<0.001) and PP, compared to the hypercholesterolemic group. Reduction in these values was significantly higher (P<0.001) than the 35.36 % (P<0.001) elicited by atorvastatin for PP. The heart rate (HR) of rats that were orally administered the extract (100 and 200 mg/kg) as well atorvastatin was lowered respectively by 7.44 %, 12.31 % and 4.27 % compared to the hypercholesterolemic group (table 2).

Data are expressed as mean±SEM (n = 6) and analyzed by one-way ANOVA followed by the Tukey post-test. aP<0.001: significantly different compared to HCR; ΔP<0.001 significantly different compared to NHR. Effect of *A. digitata* on GSH levels

Fig. 2a shows that GSH levels were significantly decreased in the heart by 52.45 % (P<0.001), aorta by 47.80 % (P<0.001) and liver by 25.53 % (P<0.001) and kidneys by 43.56 % (P<0.001) of the hypercholesterolemic treated rats compared to the normal control group. Nevertheless, the extract (100 and 200 mg/kg body weight/day) like captopril significantly prevented the decrease in GSH levels. *A. digitata* at the dose of 200 mg/kg exhibited a significant decrease of GSH in heart by 90.72 %, aorta by 63.69 % (P<0.01), liver by 19.73 % (P<0.001) and kidney by 29.21 % (P<0.01) as compared to the hypercholesterolemic group.

Effect of *A. digitata* extract on nitrites content

Fig. 2b represents the level of nitrites in aorta, heart, liver and kidney of different rat groups. Results of this study revealed hypercholesterolemic intake alone decreases the concentration of nitrites in the above tissues compared with normal control group. It decreased significantly in aorta by 48.41 % (P<0.001), heart by 45.16 % (P<0.001) and liver by 76.82 % (P<0.001) in the hypercholesterolemic group as compared to the normal group. The plant extract as well as atorvastatin prevented the deleterious effects of hypercholesterolemic in the tissues. The extract at the dose of 200 mg/kg significantly decreased the concentration of nitrite in aorta 107.47 % (P<0.001) and heart 124.83 % (P<0.001), compared to the hypercholesterolemic group.

Effect of *A. digitata* on MDA levels

MDA levels were significantly higher in heart by 54.20 %, aorta by 39.96 %, liver by 108.78 % and kidney by 95.19 % tissues of hypercholesterolemic treated rats as compared to the normal group. The administration of the plant extract prevented the rise in tissue MDA levels by 33.41 % (P<0.05) in the heart, 32.81 % (P<0.01) in aorta, 27.60 % and 36.04 % meanwhile the LDL-C by 36.04 % and 32.81 %, compared to the normal control group. The higher dose (200 mg/kg) of the extract significantly reduced in the level of total cholesterol by 27.29 %, triglycerides by 27.60 % and the LDL-C by 36.04 % meanwhile the HDL-C increased by 27.47 % when compared to SHPOC treated group. Atorvastatin (2 mg/kg) administered in addition to SHPOC significantly improved in lipid profile as compared to untreated rats. AIP and CRR were significantly elevated in all groups receiving the HPOC supplemented with egg yolk compared to the control, while CPI was decreased. Atorvastatin or aqueous extract of plant protected all groups tested against an atherogenic index.
the aorta section revealed initiation of atherosclerosis lesions with mild thickening of tunica intima which is start degeneration of endothelial cells responsible in formation of atheroma plaque. In atorvastatin and aqueous extract, the layers of artery appeared intact and few areas appeared disruption. Tunica adventitia appeared within normal limits and thickness.

**Fig. 2:** Effect of *A. digitata* on GSH (a), nitrite (b) and MDA (c) levels of HPOC supplemented with egg yolk induced hypercholesterolemic rats. Data are expressed as mean±ESM (n=6) and analyzed by one-way ANOVA followed by the Tukey post-test. aP<0.001, bP<0.01, cP<0.05: significantly different compared to HCR. **DISCUSSION**

It has been well established that nutrition plays an important role in the etiology of hypercholesterolemia and atherosclerosis. Also, several animal and human studies have confirmed the hypercholesterolemic properties of saturated fatty acids and cholesterol which include the elevated levels of TC, TG and LDL-c in serum are factors of risk for the development of atherosclerosis and other cardiovascular diseases (CVD) [20]. This study was carried out to ascertain the involvement of inflammation in hypercholesterolemia-related blood pressure elevation after consumption heated palm oil/cholesterol combined with egg yolk. We postulated that heating the palm oil repeatedly or high cholesterol would generate harmful ROS and hence induce inflammation and endothelial dysfunction. There was a significant increase in body weight at the end of the study for all the groups. This finding suggests that prolonged feeding with standard or HPOC fed supplemented with egg yolk did not affect the growth response. Non-significant reduction in the body weight was observed in the plant extract ameliorated throughout the experiment period when compared to the HPOC-fed Group.

In this study, chronic ingestion of cholesterol/heated palm oil combined with egg yolk for 10 w caused a significant increase in BP as compared to the normal control. This significant increase in blood pressure was in agreement with a previous study Adam et al. [21] showing prolonged intake of repeatedly heated palm oil increased blood pressure. We believe that the feeding of repeatedly heated...
palm oil may contribute by over-production of reactive oxygen species-related blood pressure, as indicated by the higher level of peroxide and iodine values in hypercholesterolemic group. Few studies have demonstrated the possible links between hypertension with the consumption of polar compounds in the cooking oil [22] after the increase in levels of reactive oxygen species disclose that the aqueous extract is efficient as an antihypertensive agent by significantly preventing the increase of blood pressure in diet-fed hypertensive rats. According to our results based on the antioxidative capacity of aqueous extract of A. digitata, it seems that A. digitata with its compounds is a strong inhibitor of oxidation stress, vascular inflammation and impairs the endothelial function. Oxidative stress, due to the over-production of ROS, can be diminished with aqueous extract of A. digitata by its antioxidative capacity, which can inactivate ROS and consequently counteract plasma ROS hence reduces in the amount of the blood vessel endothelium. Beside their antioxidant capacity, flavonoids improve lipid profile and have anti-inflammatory and antiatherosclerotic effects as well. This antioxidative mechanism could contribute to the protective effect against cardiovascular diseases or other chronic diseases connected with oxidative stress. The antioxidative effects of this extract may also involve the bimodal alteration in endothelial pro-inflammatory factors. The profounding provide further support to the cardiovascular protective effect of aqueous extract of A. digitata.

Rats fed HPOC diet supplemented with egg yolk at the end of experimental period acts as extrinsic inducer and significantly increase the cholesterol, triglyceride, LDL levels and decrease HDL level. This is in accord with the previous finding reported by Varsha et al. [20] who showed that feeding rats with high cholesterol diet for 10 d induced hyperlipidemia. Increase in LDL might be oxidation of LDL into oxidized low-density lipoprotein (ox-LDL) indicates the first step of atherosclerosis in cardiovascular diseases, stimulating the immune and the inflammatory reactions that initiate the process of atherosclerotic plaque buildup [23]. Numerous experimental reports showed that high cholesterol diet has increase lipid status and increased lipid level act as an indicator of establishment of hypercholesterolemia in animal models [24]. HDL cholesterol is inversely connected with total cholesterol and several evidences are available regarding this fact. Therefore, HDL has a useful effect in reducing tissue cholesterol, and increasing ratio in serum is suggested while decreasing level that for LDL-cholesterol to reduce the risk of cardiovascular diseases [25]. In addition, HDL can reduce or neutralize the atherogenic effects of oxidized LDL in artery walls. If it is taking into account the serum concentrations of total cholesterol, HDL, LDL and triglyceride in the hypercholesterolemic model. Our results indicated that the aqueous extracts of A. digitata possess a favorable effect in the management on rat's lipid profile with regard to the reduction of total cholesterol, LDL-cholesterol and triglycerides. The lipid-lowering potential of the extract may be attributed to the presence of phytoc hemical constituents such as flavonoids/polyphenols and its antioxidative capacity. Flavonoids are reported to lower LDL cholesterol and increase HDL-cholesterol concentrations in hypercholesterolemic animals [26].

It is known that reactive oxygen species (ROS) contribute to the pathogenesis of numerous cardiovascular diseases, including hypercholesterolemia. In the present work, antioxidant properties of the aqueous extract of A. digitata were determined by measuring GSH. MDA and NO activities in the tissues of hypercholesterolemic by HPOC supplemented with egg yolk. Treatment with aqueous extract of A. digitata, in our study results, improve a significant increasing free-radical-scapenging enzymes levels in tissues. The antioxidant activity of the extract was evident in vivo by the protective effects of aqueous extract of A. digitata ability to prevent lipid peroxidation. That was shown with the low levels in MDA on different organ tissues in hypercholesterolemic rat treated with the plant extract. Inhibition of lipid peroxidation and production increase of GSH may confirm the implication of the antioxidant effect of the plant extract in the treatment of hypercholesterolemia. The significant increase in tissues GSH suggested that the activation of the GSH synthetic pathway does not occur as outcome of an increased production of free radicals. Also, Olukanni et al. [27] reported molecular evidence also suggest that the ability of some phenolic compounds to activate c-glutamylcysteine synthetase (a rate-limiting enzyme in GSH synthesis). In addition, the improved reduced glutathione activity may offer an effective defense system and prevent from the damage of free radicals. MDA is one of the end-products of polyunsaturated fatty acid peroxidation and is a good indicator of the degree of lipid peroxidation [28, 29]. Our results indicated increase in MDA level in the homogenates tissues of hypercholesterolemic group, suggesting enhanced lipid peroxidation leading to tissue damage and failure of antioxidant defense mechanisms to prevent the formation of excessive free radicals. The reduced MDA content upon administration of the extract points out the favorable impact of this extract in breaking the chain reaction of lipid peroxidation engendered by chronic intake-fed. Inhibition of lipid peroxidation and production increase of GSH may confirm the implication of the antioxidant effect of the plant extract in the treatment of atherosclerosis. Similar results were obtained with Allanblacka floribunda ethanol extract when studying its antioxidative activity related to its antioxidant potential [30]. The other major free-radical which contributes to oxidative/nitrate stress is NO. NO is responsible for the relaxation of vessels and plays an important role in matching tissue perfusion to demand [31]. Considerable evidence indicates that overproduction of ROS under hypercholesterolemic conditions causes the inactivation of NO and the development of endothelial dysfunction, as well as the oxidative modification of LDL [32]. In addition, several studies demonstrated that NO is the major mediator of endothelium-dependent relaxation of rat aorta and that mechanism of vasorelaxation is impared in many pathological diseases, including hypercholesterolemia and diabetes [33]. Our results also demonstrate aqueous extract of A. digitata significantly increase the NO level in the tissues. These findings suggest that chronic treatment with plant extract increases NO bioavailability and improves hypercholesterolemia-induced endothelial dysfunction.

CONCLUSION

The findings of the present study suggest that aqueous extract of A. digitata could be a potential source of antioxidants and could have greater importance as therapeutic agent in preventing or slowing down oxidative stress-related degenerative diseases. This antioxidant activity is due mostly to compounds with hydrogen donating ability which combined with its good chelating ability for ferrous ions contributing to protect vital organs. The antioxidant activity related to the beneficial effects of A. digitata administration on hypercholesterolemia is the reduction of oxidative stress in aortic tissues. Further, studies are required to again more insight into the possible mechanism of action.

ACKNOWLEDGEMENT

The authors are thankful to the Laboratory of Medicinal Plants, Health and Galenic Formulation of the Faculty of Sciences, University of Ngaoundéré (Cameroon) for providing the facility to carry out the research.

FUNDING

Nil

AUTHORS CONTRIBUTIONS

CB and YBF proposed the plant material, harvested and prepared the crude extract. CB, YBF and AA conducted the different tests in the laboratory and analyzed the data. CB, DM and FN drafted the article. FN, TD and IDS corrected the final manuscript. All authors approved the final version of the manuscript.

COMPETING INTERESTS

The authors declare no conflict of interest.
