ON THE PROJECTIVE NORMALITY AND NORMAL PRESENTATION ON HIGHER DIMENSIONAL VARIETIES WITH NEF CANONICAL BUNDLE

JAYAN MUKHERJEE AND DEBADITYA RAYCHAUDHURY

Abstract. In this article we prove new results on projective normality and normal presentation of adjunction bundle associated to an ample and globally generated line bundle on higher dimensional smooth projective varieties with nef canonical bundle. As one of the consequences of the main theorem, we give bounds on very ampleness and projective normality of pluricanonical linear systems on varieties of general type in dimensions three, four and five. These improve known such results.

Introduction

Equations defining the embedding of a projective variety is a topic of great interest. The study of projective normality and normal presentation dates back to the time of Italian geometers. Castelnuovo first showed that a line bundle of degree greater than $2g$ on a curve of genus $g$ has a normal homogeneous coordinate ring and if the degree is greater than $2g + 1$ then the ideal of the curve is generated by quadrics. Fujita, St. Donat and Mumford, among many others, rediscovered these results years later. Mumford and his school of mathematicians carried on the study of these properties on an abelian variety of arbitrary dimension. In early 80s, Green and Lazarsfeld showed that the results of these nature are special cases of a general $N_p$ property (see [14], [15] and [16]) for curves.

We start with the definition of projective normality, normal presentation and the property $N_p$.

Definition 0.1. Let $L$ be a very ample line bundle on a variety $X$. Let the following be the minimal graded free resolution of the coordinate ring $R$ of the embedding of $X$ induced by the complete linear system $|L|$

$$
0 \longrightarrow F_n \xrightarrow{\phi_n} F_{n-1} \xrightarrow{\phi_{n-1}} \cdots \xrightarrow{\phi_1} F_0 \xrightarrow{\phi_0} R \longrightarrow 0.
$$

Let $\mathcal{I}_X$ be the ideal sheaf of the embedding.

(1) $L$ satisfies the property $N_0$ (or embeds $X$ as a projectively normal variety) if $R$ is normal.

(2) $L$ satisfies the property $N_1$ (or is normally presented) if in addition $\mathcal{I}_X$ is generated by quadrics.

(3) $L$ satisfies the property $N_p$ if in addition to satisfying the property $N_1$, the resolution is linear from the second step until the $p$-th step.

Mark Green proved that a line bundle of degree $\geq 2g + 1 + p$ on a smooth curve of genus $g$ satisfies the property $N_p$. One of the most interesting questions on surfaces concerning the $N_p$ property that has motivated lot of work is Mukai’s Conjecture: For an ample line bundle $A$ on a smooth projective surface $S$, $K_S + lA$ will satisfy the $N_p$ property if $l \geq p + 4$ ($K_S$ is the canonical bundle on $S$). This can be thought of as an analogue of Green’s result on curves for surfaces.
Mukai’s conjecture has not yet been proved even for $p = 0$. Note that by Reider’s result we have that $K_S + lA$ is very ample if $l \geq 4$ (see [33]). We state some of the results obtained on specific varieties towards this direction below.

**Elliptic Ruled Surfaces:** Y. Homma proved it for the case $p = 0$ for elliptic ruled surface (see [18] and [19]). The case $p = 1$ for elliptic ruled surfaces were proved by Gallego and Purnaprajna. The latter in fact showed that the numerical classes of normally presented divisors on an elliptic ruled surface forms a convex set and as a particular case recovered Mukai’s conjecture for $p = 0, 1$ and yield weaker bounds for higher syzygies (see [12]).

**Ruled Varieties:** Butler proves that in characteristic 0, if $E$ is a rank $n$ vector bundle on a smooth projective curve $C$ with genus $g \leq 1$ then $K_X + lA$ is projectively normal for $l \geq 2n + 1$ and satisfies the property $N_p$ for $l \geq 2n(p + 1)$ where $X = \mathbb{P}(E)$ (see [3]).

**Surfaces with Kodaira Dimension zero:** Gallego and Purnaprajna proved Mukai’s conjecture on these surfaces for $p = 0, 1$ lowering the bound by one in the latter case (see [13]).

**Abelian Varieties:** On abelian varieties Koizumi’s theorem states that the $lA$ is projectively normal for $l \geq 3$ and $A$ ample (see [23]). Kempf further proved that $lA$ is normally presented for $l \geq 4$ and $A$ ample (see [21]). The above results on abelian varieties were generalized by Pareschi where he showed that $lA$ satisfies the property $N_p$ for $l \geq p + 3$ (see [30]).

**Surfaces of General Type:** B.P. Purnaprajna proved that under mild hypothesis on an ample and globally generated line bundle $B$, $K + lB$ is projectively normal and normally presented for $l \geq 2$. He also obtained precise results on higher syzygies (See [31]).

Ein and Lazarsfeld proved that for a very ample line bundle $L$ on a smooth projective variety $X$, $K_X + (n + 1 + p)A$ satisfies the property $N_p$, (see [8]).

Another very interesting and related conjecture is the conjecture by Fujita. The precise statement is the following:

**Fujita’s Conjecture:** On a smooth projective variety of dimension $n$, $K_X + (n + 1)A$ is globally generated and $K_X + (n + 2)A$ is very ample where $A$ is an arbitrary ample line bundle.

Fujita’s conjecture has been proved for surfaces by Reider (cf. [33]) using Bogomolov’s instability theorem (see [1]) on rank two vector bundles. Fujita’s freeness conjecture has been proved by Ein and Lazarsfeld (see [7]) for $n = 3$, by Kawamata (see [20]) for $n = 3, 4$ and by Fei Ye and Zhixian Zhu (see [35]) for $n = 5$.

Mukai’s conjecture can be generalized as follows: For a smooth projective variety of dimension $n$ and an ample line bundle $A$, $K_X + lA$ satisfies the property $N_p$ for $l \geq n + p + 2$. Progress in this direction with $A$ just ample seems to be out of reach at this moment. A natural question to ask is what happens to the above conjecture if $A$ is taken to be ample and base point free instead. It is a standard argument that if $A$ is taken to be ample and base point free then Fujita’s conjecture follows in its full generality by using induction and using known results for curves. Syzygies of adjunction bundles with $A$ ample and base point free was studied in quite some details on surfaces in a series of papers written by Gallego and Purnaprajna (see [9],...,[13]). In this paper we prove new results on the properties $N_0$ and $N_1$ of the adjunction bundle $K + lB$ with $B$ ample and base point free on arbitrary dimensional smooth projective varieties with nef canonical bundle by imposing mild
conditions on the line bundle \( B \) apart from the ones mentioned above. These are analogues for results known for surfaces. Our main result regarding projective normality is the following:

**Theorem.** (See Theorem 2.3) Let \( X \) be a smooth projective variety of dimension \( n, \ n \geq 3 \). Let \( B \) be an ample and base point free line bundle on \( X \). We further assume:

(a) \( K \) is nef, \( K + B \) is base point free.
(b) \( h^0(B) \geq n + 2 \).
(c) \( h^0(K + B) \geq h^0(K) + n + 1 \).
(d) \( B - K \) is nef and effective.

Then \( K + lB \) is very ample and it embeds \( X \) as a projectively normal variety for all \( l \geq n \).

Note that, in general \( h^0(B) \geq n + 1 \) and \( h^0(K + B) \geq h^0(K) + n \) (See Remark 2.2.1) and hence the conditions are not as strong since \( B \) is ample and base point free. Using the mildness of the conditions we impose on \( B \) we come up with the following corollary :

**Corollary.** (See Corollary 2.4) Let \( X \) be a variety of dimension \( n \geq 3 \) with \( p_g \geq 2 \). Let \( B \) be an ample, globally generated line bundle on \( X \). Assume \( K \) is nef and \( B - K \) is a nef, non-zero, effective divisor. Further assume that \( B + K \) is globally generated. If either \( H^1(B) = 0 \) or \( H^{n-1}(\mathcal{O}_X) = 0 \) then \( K + nB \) will be very ample and it will embed \( X \) as a projectively normal variety.

**Sharpness of our conditions:** To discuss the sharpness of our conditions we produce two sets of examples.

In Example 2.5 we produce examples of smooth projective varieties in all dimensions satisfying all conditions of Theorem 2.3 excepting \( h^0(B) \geq n + 2 \) and show that \( K + nB \) is not projectively normal, where \( n \) is the dimension of the variety, thereby emphasizing the sharpness of the condition in the theorem.

In Example 2.6 we produce examples of smooth projective varieties in all dimensions that satisfy all conditions in Corollary 2.4 excepting the fact that \( B - K \) is nef, non-zero and effective and show that \( K + nB \) is not projectively normal, where \( n \) is the dimension of the variety, thereby showing that the condition is essential.

Our result regarding normal presentation is the following:

**Theorem.** (See Theorem 3.4 and 3.5) Let \( X \) be a smooth projective variety of dimension \( n \) with nef canonical bundle, \( n \geq 3 \). Let \( B \) be an ample and base point free line bundle on \( X \) with \( h^0(B) \geq n + 2 \). We further assume:

(a) \( K + B \) is base point free. In addition, if \( X \) is irregular then for any line bundle \( B' \equiv B, B' \) and \( K + B' \) are base point free.
(b) \( h^0(K + B) \geq h^0(K) + n + 1 \). In addition, if \( X \) is irregular then for any line bundle \( K' \equiv K, h^0(K + B) \geq h^0(K') + n + 1 \).
(c) \( (n - 2)B - (n - 1)K \) is nef and non-zero effective divisor.

Then \( K + lB \) will satisfy the property \( N_1 \) for \( l \geq n \).

Once we have these theorems, we can start looking for results using only an ample bundle if we know what multiple of that bundle is globally generated. Here solution to Fujita’s freeness Conjecture comes to play an important role.
The geometry of pluricanonical maps is of great importance in projective algebraic geometry. It was extensively studied by Bombieri, Catanese, Ciliberto, Kodaira (see [2], [4], [5], [22]). Ciliberto showed that for minimal surfaces of general type $nK$ is projectively normal for $n \geq 5$ (see [6]). B.P. Purnaprajna produces very precise and optimal bounds for normal generation and normal presentation and higher syzygies of pluricanonical series on surfaces of general type with ample canonical bundle (see [31]).

In this paper we obtain effective results on projective normality and normal presentation of pluricanonical series on smooth threefolds, fourfolds and fivefolds with ample canonical bundle. The following corollary the the summary of Corollary 4.3, 4.4, 4.5, 4.6, and 4.7:

**Corollary.** Let $X$ be a smooth projective variety of dimension $n$ with ample canonical bundle $K$.

(i) If $n = 3$, then $lK$ is very ample and embeds $X$ as a projectively normal variety for $l \geq 12$ and normally presented for $l \geq 13$.

(ii) If $n = 4$, then $lK$ is very ample and embeds $X$ as a projectively normal variety for $l \geq 24$ and normally presented for $l \geq 25$.

(iii) If $n = 5$ and $p_g(X) \geq 1$, then $lK$ is very ample and embeds $X$ as a projectively normal variety for $l \geq 35$ and normally presented for $l \geq 36$.

As far as we know this corollary has new bounds on very ampleness, projective normality and normal presentation of pluricanonical systems on threefolds, fourfolds and fivefolds.

The standard arguments using Castelnuovo-Mumford regularity yields very weak results for example for a smooth projective threefold with ample canonical bundle we have that $nK$ satisfy projective normality and normal presentation for $n \geq 14$ and $n \geq 16$ respectively. So we need more subtle methods. We build on the methods of (see [31]) and use newer ideas, one such is to use Skoda complex.

In the last section we generalize our results to projective varieties with Du-Bois singularities and hence derive some effective results on projective normality and normal presentation of pluricanonical series on projective threefolds with Q-factorial terminal Gorenstein singularities or with Canonical Gorenstein singularities.

**Acknowledgement.** We are extremely grateful to our advisor Prof. B.P. Purnaprajna for introducing us to this subject, teaching us the key concepts and guiding us throughout this work.

1. Preliminaries and Notations

Throughout this paper, we will always work on a projective variety $X$ over an algebraically closed field of characteristic zero. $K$ or $K_X$ will denote its canonical bundle. We will use the multiplicative and the additive notation of line bundles interchangeably. Thus, for a line bundle $L$, $L^{\otimes r}$ and $rL$ are the same. We have used the notation $L^{-r}$ for $(L^*)^{\otimes r}$. We will use $L'$ to denote the intersection product. The sign “$\equiv$” will be used for numerical equivalence.

Let $X$ be a smooth, projective variety and let $L$ be a globally generated line bundle on $X$. We define the bundle $M_L$ as follows.

$$
0 \longrightarrow M_L \longrightarrow H^0(L) \otimes O_X \longrightarrow L \longrightarrow 0 \quad (*)
$$
If $L$ is an ample and globally generated line bundle on $X$ one has the following characterization of the property $N_p$.

**Theorem 1.1.** Let $L$ be an ample, globally generated line bundle on $X$. If the group $H^1(\bigwedge^{p+1} M_L \otimes L^{\otimes k})$ vanishes for all $0 \leq p' \leq p$ and for all $k \geq 1$, the $L$ satisfies the property $N_p$. If in addition $H^1(L^{\otimes r}) = 0$ for all $r \geq 1$, then the above is a necessary and sufficient condition for $L$ to satisfy $N_p$.

Since we are working over a field with characteristic zero, $\bigwedge^{p+1} M_L$ is a direct summand of $M_L^{p+1}$ (see [8], Lemma 1.6). Consequently, to show that a line bundle $L$ satisfies the property $N_p$, we will show that $H^1(M_L^{p+1} \otimes L^{\otimes k}) = 0$ for all $0 \leq p' \leq p$ and for all $k \geq 1$.

The following observation has been used often in the works of Gallego and Purnaprajna (see for instance [13]).

**Observation 1.2.** Let $E$ and $L_1, L_2, \ldots, L_r$ be coherent sheaves on a variety $X$. Consider the map $H^0(E) \otimes H^0(L_1 \otimes L_2 \otimes \cdots \otimes L_r) \xrightarrow{\psi} H^0(E \otimes L_1 \otimes \cdots \otimes L_r)$ and the following maps

$$H^0(E) \otimes H^0(L_1) \xrightarrow{\alpha_1} H^0(E \otimes L_1),$$

$$H^0(E \otimes L_1) \otimes H^0(L_2) \xrightarrow{\alpha_2} H^0(E \otimes L_1 \otimes L_2),$$

$$\vdots$$

$$H^0(E \otimes L_1 \otimes \cdots \otimes L_{r-1}) \otimes H^0(L_r) \xrightarrow{\alpha_r} H^0(E \otimes L_1 \otimes \cdots \otimes L_r).$$

If $\alpha_1, \alpha_2, \ldots, \alpha_r$ are surjective then $\psi$ is also surjective.

The following from [10] relates the surjectivity of a multiplication map on a variety to the surjectivity of its restriction to a divisor.

**Lemma 1.3.** Let $X$ be a regular variety (i.e. $H^1(\mathcal{O}_X) = 0$). Let $E$ be a vector bundle and let $C$ be a divisor such that $L = \mathcal{O}_X(C)$ is globally generated and $H^1(E \otimes L') = 0$. If the multiplication map $H^0(E|_C) \otimes H^0(L|_C) \to H^0((E \otimes L)|_C)$ surjects then $H^0(E) \otimes H^0(L) \to H^0(E \otimes L)$ also surject.

The proposition below is a result from [3]. Here $\mu$ denotes the slope of a vector bundle.

**Proposition 1.4.** Let $E$ and $F$ be semistable vector bundles over a curve $C$ of genus $g$ such that $E$ is generated by its global sections. If

1. $\mu(F) > 2g$, and
2. $\mu(F) > 2g + \text{rank}(E)(2g - \mu(E)) - 2h^1(E)$.

Then the multiplication map $H^0(E) \otimes H^0(F) \to H^0(E \otimes F)$ surjects.

The following lemma from [10] is an useful tool for showing normal presentation.

**Lemma 1.5.** Let $X$ be a projective variety, let $r$ be a non-negative integer and let $F$ be a base-point-free line bundle on $X$. Let $Q$ be an effective line bundle on $X$ and let $q$ be a reduced and irreducible member of $|Q|$. Let $R$ be a line bundle and $G$ a sheaf on $X$ such that

1. $H^1(F \otimes Q^*) = 0$
2. $H^0(M^{i\otimes q}_{F \otimes Q} \otimes R \otimes \mathcal{O}_q) \otimes H^0(G) \to H^0(M^{i\otimes q}_{F \otimes Q} \otimes R \otimes G \otimes \mathcal{O}_q)$ is surjective for all $0 \leq i \leq r$.

Then for all $0 \leq i' \leq r$ and for all $0 \leq k \leq i'$,

$H^0(M^{i\otimes q}_{F} \otimes M^{i'\otimes q}_{F \otimes Q} \otimes R \otimes \mathcal{O}_q) \otimes H^0(G) \to H^0(M^{i\otimes q}_{F} \otimes M^{i'\otimes q}_{F \otimes Q} \otimes R \otimes G \otimes \mathcal{O}_q)$ is surjective.
The lemma below, a generalization of the base point-free pencil trick, is due to Green (c.f. [15], Theorem (4.e.1)):

**Lemma 1.6.** Let $C$ be a smooth, irreducible curve. Let $L$ and $M$ be line bundles on $C$. Let $W$ be a base point free linear subsystem of $H^0(C, L)$. Then the multiplication map $W \otimes H^0(M) \to H^0(L \otimes M)$ is surjective if $h^1(M \otimes L^{-1}) \leq \dim(W) - 2$.

The following lemma called the Castelnuovo-Mumford lemma (see [28]) will be used frequently in this article.

**Lemma 1.7.** Let $L$ be a base point free line bundle on a variety $X$ and let $F$ be a coherent sheaf on $X$. If $H^i(F \otimes L^{-i}) = 0$ for all $i \geq 1$ then the multiplication map $H^0(F \otimes L \otimes i) \otimes H^0(L) \to H^0(F \otimes L \otimes i + 1)$ surjects for all $i \geq 0$.

If the variety is not regular, we will not be able to use Lemma 1.3 to show the surjection of a multiplication map. To overcome the problem, we have to use the Skoda complex which is defined below. We will use it often to show the projective normality and the normal presentation on an arbitrary variety.

**Definition 1.8.** Let $X$ be a smooth projective variety of dimension $n \geq 2$. Let $B$ be a globally generated and ample line bundle on $X$.

1. Take $n - 1$ general sections $s_1, \ldots, s_{n-1}$ of $H^0(B)$ so the intersection of the divisor of zeroes $B_i = (s_i)_0$ is a nonsingular projective curve $C$, that is $C = B_1 \cap \cdots \cap B_{n-1}$.
2. Let $I$ be the ideal sheaf of $C$ and let $W = \text{span}\{s_1, \ldots, s_{n-1}\} \subseteq H^0(B)$ be the subspace spanned by $s_i$. Note that $W \subseteq H^0(B \otimes I)$. For $i \geq 1$, define the Skoda complex $I_i$ as

$$0 \longrightarrow \bigwedge^{n-1} W \otimes B^{-(n-1)} \otimes I^{i-(n-1)} \longrightarrow \cdots \longrightarrow W \otimes B^{-1} \otimes I^{i-1} \longrightarrow I^i \longrightarrow 0$$

where $I^k$ stands for $I^\otimes k$, we have used the convention that $I^k = \mathcal{O}_X$ for $k \leq 0$.

In this article we have only used $I_1$ which is the following.

$$0 \longrightarrow \bigwedge^{n-1} W \otimes B^{-(n-1)} \longrightarrow \cdots \longrightarrow \bigwedge^2 W \otimes B^{-2} \longrightarrow W \otimes B^{-1} \longrightarrow I \longrightarrow 0.$$

and it is just the Koszul resolution of $I$.

Even though our main theorems deal with the adjunction bundle associated to an ample and globally generated line bundle, in section 4 we deduce some results on three, four and five folds that deal with the pluricanonical series when the canonical bundle is just an ample line bundle. In order to make this transition, we need Fujita’s freeness conjecture on three, four and five folds or a slightly stronger version of it (see [7] and [20]). In particular, we need the following three results.

**Theorem 1.9.** (See [20], Theorem 3.1) Let $X$ be a normal projective variety of dimension 3, $L$ an ample Cartier divisor, and $x_0 \in X$ a smooth point. Assume that there are positive numbers $\sigma_p$ for $p = 1, 2, 3$ which satisfy the following conditions:

1. $\sqrt[p]{L^p \cdot W} \geq \sigma_p$ for any subvariety $W$ of dimension $p$ which contains $x_0$.
2. $\sigma_1 \geq 3$, $\sigma_2 \geq 3$ and $\sigma_3 > 3$.

Then $|K_X + L|$ is free at $x_0$. 

Corollary 1.10. (See [20], Corollary 3.2) Let \( X \) be a smooth projective variety of dimension 3, and \( H \) an ample divisor. Then \( |K_X + mH| \) is free if \( m \geq 4 \). Moreover, if \( H^3 \geq 2 \), then \( |K_X + 3H| \) is also free.

Theorem 1.11. (See [20], Corollary 4.2) Let \( X \) be a smooth projective variety of dimension 4, and \( H \) an ample divisor. Then \( |K_X + mH| \) is free if \( m \geq 5 \).

The remark after the following result from [27] will be used in sections 4.

Theorem 1.12. Let \( k \) be an algebraically closed field of characteristic 0 and \( X \) a normal projective \( \mathbb{Q} \)-Gorenstein variety of dimension \( n \geq 2 \) with singular locus of codimension \( \geq 3 \). Assume that the canonical divisor \( K_X \in \text{Pic}(X) \otimes \mathbb{Q} \) is nef. Let \( \rho : Y \to X \) be any resolution of the singularities. Then for arbitrary ample divisors \( H_1, \ldots, H_{n-2} \), we have the following inequality:

\[
(3c_2(Y) - c_1^2(Y))\rho^*(H_1) \cdots \rho^*(H_{n-2}) \geq 0
\]

Remark 1.12.1. An obvious corollary of the theorem above is the following: Let \( X \) be a smooth three (resp. four) fold and \( A \) be an ample divisor on it. Then \( A.c_2 \geq 0 \) (resp. \( A^2.c_2 \geq 0 \)).

2. Projective Normality for Adjoint Linear Series

All the varieties appearing in this section are smooth. Here we will prove theorems on projective normality and normal presentation of adjoint linear series associated to a globally generated, ample line bundle. The proofs here are based on the philosophy that a multiplication map surjects on a variety if its restriction surjects on a certain curve. To prove this, we will use the Skoda complex defined in section 1 as the variety we are working on is not necessarily regular.

Lemma 2.1. Let \( X \) be a variety of dimension \( n, n \geq 3 \). Let \( B \) be an ample and base point free line bundle on \( X \). We further assume \( h^0(B) \geq n + 2 \).

Let \( X_n \) be \( X, X_{n-j} \) be a smooth irreducible \((n-j)\) fold chosen from the complete linear system of \(|B|_{X_{n-j}}\) (which exists by Bertini) for all \( 1 \leq j \leq n - 1 \).

Then the following will hold:

(i) \( H^1(K + lB|_{X_{n-j}}) = 0 \) for all \( 0 \leq j \leq n - 2, l \geq n - 1 \).

(ii) \( H^0(K + nB) \otimes H^0(B) \to H^0(K + (n + 1)B) \) surjects.

Proof of (i). By adjunction, \( K_{X_{n-j}} = (K + jB)|_{X_{n-j}} \) for all \( 0 \leq j \leq n - 1 \). By Kodaira Vanishing, \( H^1(K + lB|_{X_{n-j}}) = H^1(K_{X_{n-j}} + (l-j)B|_{X_{n-j}}) = 0 \) for all \( 0 \leq j \leq n - 2, l \geq n - 1 \).

Proof of (ii). Thanks to part (i), \( H^0((K + lB)|_{X_{n-j}}) \to H^0((K + lB)|_{X_{n-j-1}}) \) surjects for all \( l \geq n, 0 \leq j \leq n - 2 \). We have the following situation (2.1.1):

\[
\begin{array}{c}
0 \to H^0(L) \otimes H^0(B) \otimes \mathcal{I} \to H^0(L) \otimes H^0(B) \to H^0(L) \otimes V \to 0 \\
\downarrow \quad \downarrow \quad \downarrow \quad \downarrow \\
0 \to H^0((L + B) \otimes \mathcal{I}) \to H^0(L + B) \to H^0((L + B)|_{X_1}) \to 0
\end{array}
\]

Here \( L = K + nB, \mathcal{I} \) is the ideal sheaf of the curve \( X_1 \) in \( X \) and \( V \) is the cokernel of the map \( H^0(B \otimes \mathcal{I}) \to H^0(B) \). The bottom row is exact by part (i) and the top row is exact by the definition of \( V \).
Let $W$ be the vector space corresponding to the curve $X_1$ on $X$ that appears on the Skoda complex (see Definition 1.8).

Consequently, tensoring the following exact sequence (2.1.2):

$$0 \rightarrow \bigwedge^{n-1} W \otimes B^{-(n-1)} \rightarrow \ldots \rightarrow \bigwedge^2 W \otimes B^{-2} \rightarrow \bigwedge W \otimes B^{-1} \rightarrow \mathcal{I} \rightarrow 0$$

by $L + B$, we get the following exact sequence where $L' = L + B$

$$0 \rightarrow \bigwedge^{n-1} W \otimes L' \otimes B^{-(n-1)} \rightarrow \ldots \rightarrow \bigwedge W \otimes L' \otimes B^{-1} \rightarrow \bigwedge W \otimes L' \otimes \mathcal{I} \rightarrow 0$$

To show the leftmost vertical map in (2.1.1) surjects, it is enough to prove $H^1(\ker(f_1)) = 0$ as $W \subseteq H^0(B \otimes \mathcal{I})$. The following two claims prove the vanishing.

Claim 1: $H^r(\ker(f_r)) = 0 \Rightarrow H^{r-1}(\ker(f_{r-1})) = 0$ for all $2 \leq r \leq n - 2$.

**Proof:** We have the following short exact sequence:

$$0 \rightarrow \ker(f_r) \rightarrow \bigwedge W \otimes L' \otimes B^{-r} \rightarrow \ker(f_{r-1}) \rightarrow 0$$

The long exact sequence of cohomology proves the claim as $H^{r-1}(K + (n + 1 - r)B) = 0$ since $n + 1 - r > 0$ for $r$ in the given interval.

Claim 2: $H^{n-2}(L' - (n - 1)B) = 0$.

**Proof:** This is obvious from Kodaira vanishing as $H^{n-2}(L' - (n - 1)B) = H^{n-2}(K + 2B) = 0$.

Therefore, in order to prove the surjectivity of the middle vertical map in (2.1.1), we only have to prove the surjectivity of the following map $H^0(L|_{X_1}) \otimes V \rightarrow H^0((L + B)|_{X_1})$ as $H^0(L|_{X_{n-j}}) \rightarrow H^0((L + B)|_{X_{n-j}})$ already surjects for all $0 \leq j \leq n - 2$ by part (i).

Using Lemma 1.6, it is enough to prove the following inequality:

$$h^1((K + (n - 1)B)|_{X_1}) \leq \dim(V) - 2. \quad (2.1.3)$$

So, first we have to find an estimate of $\dim(V)$.

Claim 3: $h^0(B \otimes \mathcal{I}) = \dim(W)$.

**Proof:** We tensor the exact sequence (2.1.2) by $B$ and get the following exact sequence:

$$0 \rightarrow \bigwedge^{n-1} W \otimes B^{-(n-2)} \rightarrow \ldots \rightarrow \bigwedge^2 W \otimes B^{-1} \rightarrow \bigwedge W \otimes \mathcal{O}_X \rightarrow \bigwedge W \otimes B \otimes \mathcal{I} \rightarrow 0$$

So, in order to prove the claim, it is enough to show $H^0(\ker(g_1)) = 0$ and $H^1(\ker(g_1)) = 0$. These two vanishing can be seen from the following four facts whose proofs we omit as they are similar to Claim 7 and Claim 2.

Fact 1: $H^{r-1}(\ker(g_r)) = 0 \Rightarrow H^{r-2}(\ker(g_{r-1})) = 0$ for all $2 \leq r \leq n - 2$.

Fact 2: $H^{n-3}(B^{-(n-2)}) = 0$.

Fact 3: $H^r(\ker(g)) = 0 \Rightarrow H^{r-1}(\ker(g_{r-1})) = 0$ for all $2 \leq r \leq n - 2$.

Fact 4: $H^{n-2}(B^{-(n-2)}) = 0$.

Therefore, $\dim(V) = h^0(B) - h^0(B \otimes \mathcal{I}) \geq h^0(B) - (n - 1)$ as $\dim(W) \leq n - 1$. Note that $(K + (n - 1)B)|_{X_1}$ is the canonical bundle of $X_1$ and consequently $h^1((K + (n - 1)B)|_{X_1}) = 1$. So, the inequality \[2.1.3\] is verified thanks to $h^0(B) \geq n + 2$. □
Remark 2.1.1. Since $B$ is ample, $h^0(B) \geq n+1$. In our theorems, we are assuming that $h^0(B) \geq n+2$.
Later we will give an example where $h^0(B) = 4$ and $K + 3B$ does not satisfy projective normality on a regular three-fold.

Lemma 2.2. Let $X$ be a variety of dimension $n$, $n \geq 3$. Let $B$ be an ample and base point free line bundle on $X$. We further assume:

(a) $K$ is nef, $K + B$ is base point free.
(b) $h^0(K + B) \geq h^0(K) + n + 1$.
(c) $B - K$ is nef and effective divisor.

Let $X_n$ be $X$, $X_{n-j}$ be sufficiently general smooth irreducible $(n - j)$ fold chosen from the complete linear system of $(K + B)|_{X_{n-j}}$ for all $1 \leq j \leq n - 1$.
Then the following will hold:
(i) $H^1(2n - 2B|_{X_{n-j}}) = 0$ for all $0 \leq j \leq n - 2$.
(ii) $H^0(K + (2n - 1)B) \otimes H^0(K + B) \to H^0(2K + 2nB)$ surjects.

Proof of (i). Adjunction gives us $K_{X_{n-j}} = ((j + 1)K + jB)|_{X_{n-j}}$ for all $0 \leq j \leq n - 1$.
We have $H^1(2n - 2B|_{X_{n-j}}) = H^1(K_{X_{n-j}} + ((2n - 2j - 3)B + (j + 1)(B - K))|_{X_{n-j}})$.
Note that, $2n - 2j - 3 \geq 1$ for all $0 \leq j \leq n - 2$.
Using Kodaira vanishing we conclude $H^1((2n - 2B|_{X_{n-j}}) = 0$ for all $0 \leq j \leq n - 2$ as $B - K$ is nef.

Proof of (ii). Let $\mathcal{I}$ be the ideal sheaf of $X_1$ in $X$ and consequently we have $W$ as in Definition 1.8.
We have the following situation (2.2.1) where $L = K + (2n - 1)B$ and $V$ is the cokernel of the map $H^0((K + B) \otimes \mathcal{I}) \to H^0(K + B)$:

\[
\begin{array}{cccccc}
0 & \to & H^0(L) \otimes H^0((K + B) \otimes \mathcal{I}) & \to & H^0(L) \otimes H^0(K + B) & \to & H^0(L) \otimes V & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \to & H^0((L + K + B) \otimes \mathcal{I}) & \to & H^0((L + K + B)) & \to & H^0((L + K + B)|_{X_1}) & \to & 0
\end{array}
\]

The bottom row is exact by Kodaira vanishing as $H^1((K + (2n - 1)B)|_{X_{n-j}}) = 0$, the top row is exact by our construction.
We have the following exact sequence:

\[
0 \to \bigwedge^{n-1} W \otimes (K + B)^{-1} \to \ldots \to W \otimes (K + B)^{-1} \otimes \mathcal{I} \to 0
\]

Tensoring by $L + K + B$ and taking cohomology, as in the proof of Lemma 2.1, we have the following two vanishings:

(V-1) $H^{r-1}(L + K + B - r(K + B)) = H^{r-1}(K + (2n - 2r + 1)B + (r - 1)(B - K)) = 0$ for all $2 \leq r \leq n - 2$
which is obvious by Kodaira vanishing since we have $B - K$ nef.

(V-2) $H^{n-2}(L + K + B - (n - 1)(K + B)) = 0$ which comes from Kodaira vanishing as well.

The above two vanishings show that the leftmost vertical map in (2.2.1) is surjective.
Note that $H^0(L) \to H^0(L|_{X_1})$ is surjective by part (i). Consequently, by the application of Lemma 1.6 we just need the following inequality:

\[
h^1((2n - 2B|_{X_1}) \leq \text{dim}(V) - 2 \quad (2.2.2)
\]
As in the proof of Claim 3, Lemma 2.1, we can see that $\dim(V) \geq h^0(K + B) - (n - 1)$.

Still, we have to estimate $h^1((2n - 2)B)_{|X_1|}$. We have the short exact sequence:

$$
0 \longrightarrow (-K - B)_{|X_2|} \longrightarrow \mathcal{O}_{X_2} \longrightarrow \mathcal{O}_{X_1} \longrightarrow 0
$$

Tensoring this by $(2n - 2)B$ gives:

$$
0 \longrightarrow (-K + (2n - 3)B)_{|X_2|} \longrightarrow (2n - 2)B_{|X_2|} \longrightarrow (2n - 2)B_{|X_1|} \longrightarrow 0
$$

Consequently, we have the long exact sequence:

$$
\ldots \longrightarrow H^1((2n - 2)B)_{|X_2|} \longrightarrow H^1((2n - 2)B)_{|X_1|} \longrightarrow H^2((-K + (2n - 3)B)_{|X_2|}) \longrightarrow \ldots
$$

Since $H^1((2n - 2)B)_{|X_2|} = 0$ by (i), we get $h^1((2n - 2)B)_{|X_1|} \leq h^2((-K + (2n - 3)B)_{|X_2|})$.

Now, we have $h^2((-K + (2n - 3)B)_{|X_2|}) = h^0((-1)K + (n - 2)B + K - (2n - 3)B)_{|X_2|}) = h^0(K_{X_2} - (n - 1)(B - K)_{|X_2|})$.

Note that, assumption (c) gives us $h^0(K_{X_2} - (n - 1)(B - K)_{|X_2|}) \leq h^0(K_{X_2})$.

The long exact sequence associated to the following short exact sequence:

$$
0 \longrightarrow (-B)_{|X_{n-j-1}} \longrightarrow K_{|X_{n-j-1}} \longrightarrow K_{X_{n-j}} \longrightarrow 0
$$

shows us (by Kodaira Vanishing) that $h^0(K_{|X_{n-j}}) = h^0(K_{|X_{n-j+1}})$ for all $0 \leq j \leq n - 2$.

Consequently we get that $h^0(K_{|X_{n-j}}) = h^0(K)$.

So in order to show inequality (2.2.2) it is enough to show $h^0(K) \leq h^0(K + B) - (n + 1)$ which we have, thanks to assumption (b).

**Remark 2.2.1.** We always have $h^0(K + B) \geq h^0(K) + n$ on any $n$ fold if $K + B$ and $B$ are ample and base point free.

**Proof:** Note that, $h^0(K + B) - h^0(K)$ is the dimension of the cokernel of the map $H^0(K) \rightarrow H^0(K + B)$ in $H^0((K + B)_{|X_{n-1}})$ where $X_{n-1}$ is a smooth irreducible divisor chosen from the complete linear system of $B$.

But the cokernel is a base point free linear subsystem of the complete linear series of $(K + B)_{|X_{n-1}}$ (on the $n - 1$ dimensional variety). Note that $(K + B)_{|X_{n-1}}$ is ample and base point free. If we choose any $n - 1$ sections from the linear system of $(K + B)_{|X_{n-1}}$, they will intersect. □

**Remark 2.2.2.** Let $X$ be a variety of dimension $n$ with nef canonical bundle $K$. Let $B$ be an ample and base point free line bundle such that $B + K$ is globally generated, $h^0(B) \geq n + 2$ and $H^1(B) = 0$. Then $h^0(K + B) \geq h^0(K) + n + 1$.

**Proof:** The assertion is trivial if $h^0(K) = 0$ or if $K = \mathcal{O}_X$. Otherwise, we have the short exact sequence:

$$
0 \longrightarrow B \longrightarrow B + K \longrightarrow (B + K)_{|\mathcal{X}} \longrightarrow 0
$$

where $\mathcal{X}$ is a non zero effective divisor chosen from the linear system of $K$.

From the long exact sequence, we get that $h^0(K + B) = h^0(B) + h^0((B + K)_{|\mathcal{X}})$.

But $h^0((B + K)_{|\mathcal{X}}) \geq h^0(K_{|\mathcal{X}})$.

Hence, $h^0(K + B) = h^0(B) + h^0((B + K)_{|\mathcal{X}}) \geq n + 2 + h^0(K) - 1$. □

**Remark 2.2.3.** Let $X$ be a variety of dimension $n$ with nef canonical bundle $K$ and $H^{n-1}(\mathcal{O}_X) = 0$. Let $B$ be an ample and base point free line bundle on $X$ such that $B + K$ is globally generated and $h^0(B) \geq n + 2$. Then $h^0(K + B) \geq h^0(K) + n + 1$. 

Proof: Again, we can assume that $K$ is a non zero effective divisor. The long exact sequence associated to the short exact sequence:

$$0 \rightarrow K \rightarrow B + K \rightarrow (B + K)|_{\mathcal{D}} \rightarrow 0$$

gives $h^0(K + B) = h^0(K) + h^0((B + K)|_{\mathcal{D}})$ (here $\mathcal{D}$ is a sufficiently general non zero effective divisor chosen from the linear system of $B$).

Now we have $h^0((B + K)|_{\mathcal{D}}) \geq h^0(B|_{\mathcal{D}})$.

Hence $h^0(K + B) \geq h^0(K) + h^0(B|_{\mathcal{D}}) \geq h^0(K) + n + 1$.

Now we prove our first main result that gives the projective normality of $K + nB$ on a regular $n$ dimensional variety under some assumptions.

**Theorem 2.3.** Let $X$ be a variety of dimension $n$, $n \geq 3$. Let $B$ be an ample and base point free line bundle on $X$. We further assume:

(a) $K$ is nef, $K + B$ is base point free.
(b) $h^0(B) \geq n + 2$.
(c) $h^0(K + B) \geq h^0(K) + n + 1$.
(d) $B - K$ is nef and effective.

Then $K + lB$ is very ample and it embeds $X$ as a projectively normal variety for all $l \geq n$.

**Proof.** We need to prove $H^0((K + lB)^{\otimes k}) \otimes H^0(K + lB) \rightarrow H^0((K + lB)^{\otimes k+1})$ surjects.

**Step 1:** $H^0(k(K + lB) + rB) \otimes H^0(B) \rightarrow H^0(k(k + lB) + (r + 1)B)$ surjects for $k \geq 2, l \geq n, r \geq 0$.

This comes from CM lemma (Lemma 1.7) once we note that $H^0(k(k + lB) + (r - i)B) = H^0(K + (k - 1)K + rB + (kl - i)B) = 0$ for all $1 \leq i \leq n$ by Kodaira vanishing.

**Step 2:** $H^0(k(k + lB) + (l - 1)B) \otimes H^0(K + B) \rightarrow H^0((k + 1)K + (kl + l)B)$ surjects for $k \geq 2, l \geq n$.

This again comes from CM lemma (Lemma 1.7).

Note that $H^0(k(k + lB) + (l - 1)B - iK - iB) = H^0(K + kK + (kl + l - 1 - i)B - (1 + i)K)$.

But $kl + l - 1 - i \geq 3n - 1 - i \geq 2n - 1 > 1 + n$ for all $1 \leq i \leq n$.

Since assumption (d) shows us that $B - K$ is nef, Kodaira vanishing gives $H^0(k(k + lB) + (l - 1)B - iK - iB) = 0$ for all $1 \leq i \leq n$.

**Step 3:** $H^0((K + lB)^{\otimes k}) \otimes H^0(K + lB) \rightarrow H^0((k + lB)^{\otimes k+1})$ surjects for $k \geq 2, l \geq n, r \geq 0$.

This comes from Step 1 and the Observation 1.2.

So, we only need to prove $H^0(K + lB) \otimes H^0(K + lB) \rightarrow H^0((K + lB)^{\otimes 2})$ surjects for all $l \geq n$.

**Step 4:** $H^0(K + lB) \otimes H^0(B) \rightarrow H^0(K + (l + 1)B)$ surjects for $l > n$.

This comes from CM lemma (Lemma 1.7) once we note that $H^0(K + (l - i)B) = 0$ for all $1 \leq i \leq n$ by Kodaira vanishing since $l - i > 0$.

**Step 5:** $H^0(K + (2l - 1)B) \otimes H^0(K + B) \rightarrow H^0(2K + 2lB)$ surjects for $l > n$.

Note that $H^0(K + (2l - 1)B - iK - iB) = H^0(K + (2l - i - 1)B - iK)$.

Now, $2l - i - 1 \geq 2n - i + 1 > i$, thanks to $l \geq n + 1$ and $1 \leq i \leq n$.

Since $B - K$ is nef, Kodaira vanishing implies $H^0(K + (2l - 1)B - iK - iB) = 0$.

Hence by CM lemma (Lemma 1.7), we are done.
Step 6: $H^0(K + lB) \otimes H^0(K + lB) \to H^0(2K + 2lB)$ surjects for $l > n$.
This comes from Step 4 and the Observation 1.2.

So, we only need to prove $H^0(K + nB) \otimes H^0(K + nB) \to H^0(2K + 2nB)$ surjects which is our final step.

Step 7: $H^0(K + nB) \otimes H^0(K + nB) \to H^0(2K + 2nB)$ surjects.
In Lemma 2.1, we have already proved $H^0(K + nB) \otimes H^0(B) \to H^0(K + (n + 1)B)$ surjects and in Step 2 we have showed $H^0(K + lB) \otimes H^0(B) \to H^0(K + (l + 1)B)$ surjects for $l > n$.
Using Observation 1.2, we will be done if we can show the surjection of $H^0(K + (2n - 1)B) \otimes H^0(K + B) \to H^0(2K + 2nB)$ which we have proved in Lemma 2.2.

Remark 2.3.1. Let $X$ be a $n$ dimensional variety. Let $B$ be a globally generated, ample line bundle on $X$. We further assume that $B - K$ is a non-zero effective divisor. If $p_g(X) \geq 2$ Then $h^0(B) \geq n + 2$.

Proof: The long exact sequence associated to the short exact sequence:

$$0 \longrightarrow K \longrightarrow B \longrightarrow B_D \longrightarrow 0$$

shows that the cokernel of the map $H^0(K) \to H^0(B)$ is a base point free linear subsystem of the base point free complete linear system of $H^0(B_D)$ ($D$ is an element of the linear series of $B - K$).

By the same argument used in the proof of Remark 2.2.1 we have $h^0(B) - p_g \geq n$. □

Remark 2.3.1 and Remark 2.2.2, 2.2.3 allow us to deduce a corollary of Theorem 2.3 which we state below.

Corollary 2.4. Let $X$ be a variety of dimension $n \geq 3$ with $p_g \geq 2$. Let $B$ be an ample, globally generated line bundle on $X$. Assume $K$ is nef and $B - K$ is a nef, non-zero, effective divisor. Further assume that $B + K$ is globally generated. If either $H^1(B) = 0$ or $H^{n-1}(\mathcal{O}_X) = 0$ then $K + nB$ will be very ample and it will embed $X$ as a projectively normal variety. □

Now we produce examples to discuss the sharpness of our conditions. In our first example, we construct a regular variety and an ample, globally generated line bundle on it that satisfies all the conditions of Theorem 2.3 except the condition (b) and show that the line bundle does not satisfy the property $N_0$.

Example 2.5. Consider a double cover $X$ of $\mathbb{P}^{n+1}$ ramified along an $n$-fold of degree $2n + 4$, $n \geq 3$.

Let the finite morphism from $X$ to $\mathbb{P}^{n+1}$ be denoted by $f$. The unique line bundle associated to this cover is $\mathcal{O}(n + 2)$.

We have $f_* (\mathcal{O}_X) = \mathcal{O} \oplus \mathcal{O}(-n - 2)$, $H^1 (\mathcal{O}_X) = 0$ and $K_X = \mathcal{O}_X$.

Consider $B = f^* \mathcal{O}(1)$. Clearly $B$ is ample and base point free.

$H^0(B) = H^0(f_* (\mathcal{O}_X)) = H^0(\mathcal{O}(1) \oplus \mathcal{O}(-n - 1)) \Longrightarrow h^0(B) = n + 2$. Kodaira vanishing shows that $H^1(rB) = 0$ for all $r \geq 1$.

Let $Y \in |B|$ be smooth irreducible $n$ fold given by Bertini’s Theorem. Consider the line bundle $B|_Y$ on $Y$. This is again ample and base point free and by adjunction $K_Y = B|_Y$. So $Y$ is a smooth $n$-fold of general type. Consider the following exact sequence:

$$0 \longrightarrow B^* \longrightarrow \mathcal{O}_X \longrightarrow \mathcal{O}_Y \longrightarrow 0 \quad (2.5.1)$$

Taking cohomology and using Kodaira vanishing, we get $H^1(\mathcal{O}_Y) = 0$.

Tensoring the sequence (2.5.1) by $B$ and taking cohomology gives us $h^0(B|_Y) = h^0(B) - 1 = n + 1$. Hence $B|_Y$ does not satisfy the condition (b) of Theorem 2.3.
We have that $K_Y + B|_Y = 2B|_Y$ and is hence base point free. Clearly $K_Y = B|_Y$ is nef since it is ample. Also $B|_Y - K_Y = \mathcal{O}_{\mathcal{Y}}$ and is hence nef and effective. Now we show that $h^0(K_Y + B|_Y) \geq h^0(K_Y) + n + 1$ that is $h^0(2B|_Y) \geq h^0(B|_Y) + n + 1$.

We have that $H^0(2B) = H^0(f^{+} \mathcal{O}(2)) = H^0(\mathcal{O}(2) \bigoplus \mathcal{O}(-n))$

\[ \implies h^0(2B) = h^0(\mathcal{O}(2)) = \left(\frac{n+2}{2}\right) + (n + 2). \]

Tensoring the exact sequence 2.5.1 by 2B and taking the cohomology shows that $h^0(2B|_Y) = h^0(2B) - h^0(B) = \left(\frac{n+2}{2}\right).$ Now, $h^0(B|_Y) + n + 1 = 2n + 2$.

Since $n \geq 3$ we have that $h^0(K_Y + B|_Y) \geq h^0(K_Y) + n + 1$.

We have showed that $B|_Y$ satisfies all the conditions in Theorem 2.3 except (b). Now we prove that $K_Y + nB|_Y = (n + 1)B|_Y$ does not satisfy property $N_0$.

Claim 2.5.2: Let $X$ be a smooth regular variety and let $L$ be an ample and base point free line bundle on $X$ with $H^1(rL) = 0$ for all $r \geq 1$. Let $Y$ be a smooth irreducible member chosen from the linear system $|L|$ according to Bertini’s Theorem. Then $L$ satisfies the property $N_0$ iff $L|_Y$ satisfies the property $N_0$.

Proof: Consider the following exact sequence:

\[ 0 \rightarrow \mathcal{O}_X \rightarrow L \rightarrow L|_Y \rightarrow 0 \quad (2.5.3) \]

Taking cohomology and tensoring with $H^0(L^\otimes k)$ we get the following commutative diagram where the horizontal sequences are exact:

\[
\begin{array}{cccccc}
0 & \rightarrow & H^0(\mathcal{O}_X) \otimes H^0(L^\otimes k) & \rightarrow & H^0(L) \otimes H^0(L^\otimes k) & \rightarrow & H^0(L|_Y) \otimes H^0(L^\otimes k) & \rightarrow & 0 \\
& & \downarrow & & \downarrow & & \downarrow & & \\
0 & \rightarrow & H^0(L^\otimes k) & \rightarrow & H^0(L^\otimes k+1) & \rightarrow & H^0(L|_Y^\otimes k+1) & \rightarrow & 0 \\
\end{array}
\]

Now the left hand vertical map is surjective and hence the middle map surjects iff the right hand vertical map surjects. Tensoring the exact sequence 2.5.3 by $L^\otimes k-1$ and then taking cohomology we have that the following sequence is exact:

\[
0 \rightarrow H^0(L^\otimes k-1) \rightarrow H^0(L^\otimes k) \rightarrow H^0(L|_Y^\otimes k) \rightarrow H^1(L^\otimes k-1)
\]

Now the last term is 0 by our assumption and hence $H^0(L^\otimes k) \rightarrow H^0(L|_Y^\otimes k)$ surjects. Hence the middle vertical map surjects if and only if $H^0(L|_Y) \otimes H^0(L|_Y^\otimes k) \rightarrow H^0(L|_Y^\otimes k+1)$ surjects. Hence $L$ has the property $N_0$ iff $L|_Y$ has $N_0$ and the claim is proved.

We note that since $X$ is regular so is $Y$ and $L|_Y$ is an ample and base point free line bundle on $Y$. So if $C$ is a curve section of $L$ we get by the above claim that $L$ has the property $N_0$ iff $L|_C$ has the property $N_0$.

Now we prove the following claim which concludes the example.

Claim (2.5.3): $K_Y + nB|_Y$ is not projectively normal.

Proof: We have that $K_Y + nB|_Y = (n + 1)B|_Y$. Suppose $(n + 1)B|_Y$ satisfies the property $N_0$. By the paragraph above, we have that $(n + 1)B$ satisfies the property $N_0$ and is in particular very ample. Hence for a curve section $C \in |B|$ we have that $(n + 1)B|_C$ is very ample.

We also have that $K_C = nB|_C$ and hence $(n + 1)B|_C = K_C + B|_C$.

Now $\text{deg}(B|_C) = B'^{n+1} = 2H^{n+1} = 2$ where $H$ is a hyperplane section of $\mathbb{P}^{n+1}$ since the map $f$ is
2 : 1.
But $K_C + E$ cannot be very ample if $E$ is an effective divisor of degree 2. \hfill $\Box$

Now we give an example of a variety and an ample, globally generated line bundle $B$ which does not satisfy the property $N_0$, where $B - K$ is neither nef nor effective although the geometric genus of the variety is large (see Corollary 2.4).

**Example 2.6.** Consider $X$ a cyclic double cover of $\mathbb{P}^n$ ramified along hypersurface of degree $2r$. Denote by $f$ the morphism from $X$ to $\mathbb{P}^n$. Let $B = f^*(\mathcal{O}(1))$. We have that $f_*(\mathcal{O}_X) = \mathcal{O} \oplus \mathcal{O}(-r)$, $K_X = f^*(\mathcal{O}(-n + 1 + r))$, $K_X + B = f^*(\mathcal{O}(-n + r))$, $B - K_X = f^*(\mathcal{O}(n + 2 - r))$.

We can see that for $r \geq n + 3$, $B - K_X$ is not nef. However by making $r$ large enough we can make $p_g$ as large as we wish to and in particular make $p_g \geq 2$. We also have $H^1(B) = 0$. We now show that for $r \geq n + 3$, $K_X + nB$ is not projectively normal.

Indeed, $K_X + nB = f^*(\mathcal{O}(r - 1)) \implies H^0(K_X + nB) = H^0(\mathcal{O}(r - 1) \oplus \mathcal{O}(-1)) = H^0(\mathcal{O}(r - 1))$.

Now $H^0(2K_X + 2nB) = H^0(f^*(\mathcal{O}(2r - 2))) = H^0(\mathcal{O}(2r - 2)) \oplus H^0(\mathcal{O}(r - 2))$.

If $r \geq 2$ we can clearly see that $K + nB$ is not projectively normal. Hence we can see that the condition $B - K_X$ nef and effective is essential in Corollary 2.4. \hfill $\blacksquare$

### 3. Normal Presentation for Adjoint Linear Series

Our goal is to prove results concerning the $N_1$ property of adjunction bundles. Unlike the previous section, first we prove results for regular varieties and then we prove a weaker result for irregular varieties. We prove three technical lemmas to begin with. The proofs are again based on the same philosophy that a multiplication map surjects on a variety if it surjects on a curve section. All the varieties in this section are smooth.

**Lemma 3.1.** Let $X$ be a regular variety of dimension $n$, $n \geq 3$. Let $B$ be an ample and base point free line bundle on $X$. We further assume $h^0(B) \geq n + 2$.

Let $X_n$ be $X$, $X_{n-j}$ be a smooth irreducible $(n - j)$ fold chosen from the complete linear system of $|B|_{X_{n-j}}$ (which exists by Bertini) for all $1 \leq j \leq n - 1$.

Then the map $H^0((K + nB)|_{X_{n-j}}) \otimes H^0(B)|_{X_{n-j}} \rightarrow H^0((K + (n + 1)B)|_{X_{n-j}})$ surjects.

**Proof.** Because of the vanishing $[2.1(i)]$ by the repeated application of Lemma 1.3, it is enough to prove $H^0((K + nB)|_{X_j}) \otimes H^0(B)|_{X_j} \rightarrow H^0((K + (n + 1)B)|_{X_j})$ surjects.

To show this using Lemma 1.6 we have to prove the inequality $h^1((K + (n - 1)B)|_{X_j}) \leq h^0(B)|_{X_j} - 2$ which follows directly from our assumption that $h^0(B) \geq n + 2$. \hfill $\blacksquare$

**Lemma 3.2.** Let $X$ be a regular $n$ fold, $n \geq 3$. Let $B$ be an ample and base point free line bundle on $X$. We further assume:

(a) $K$ is nef, $K + B$ is base point free.

(b) $h^0(K + B) \geq h^0(K) + n + 1$.

(c) $(n - 2)B - (n - 1)K$ is nef and effective.

Let $X_n$ be $X$, $X_{n-j}$ is sufficiently general smooth irreducible $(n - j)$ fold chosen from the complete linear system of $|(K + B)|_{X_{n-j}}$ for all $1 \leq j \leq n - 1$.

Then the following will hold:

(i) $H^1((2n - 3)B)|_{X_{n-j}} = 0$ for all $0 \leq j \leq n - 2$.

(ii) $H^0((K + (2n - 2)B)|_{X_{n-j}}) \otimes H^0((K + B)|_{X_{n-j}}) \rightarrow H^0((2K + (2n - 1)B)|_{X_{n-j}})$ surjects for all $0 \leq j \leq n - 1$. 

Then H-linear system of Lemma 3.3.

Hence, we have to prove the surjection of \( H^1((2n-3)B|_{X_n}) \).

Note that, \( B - \frac{j + 1}{2n - 4 - j} K = B - \frac{n - 1}{n - 2} K + \frac{n - 1}{n - 2} K - \frac{j + 1}{2n - 4 - j} K. \)

We have \( n - 1 \geq j + 1 \) and \( n - 2 \leq 2n - 4 - j \) for all \( 0 \leq j \leq n - 2 \). Consequently, \( (2n - 4 - j)B - (j + 1)K \) is nef as \( K \) and \( B - \frac{n - 1}{n - 2} K \) are nef.

Using Kodaira vanishing we conclude \( H^1((2n-3)B|_{X_n}) = 0 \) for all \( 0 \leq j \leq n - 2 \).

**Proof of (ii).** Repeated application of Lemma 1.3 shows that it is enough to prove the lemma for \( j = n - 1 \).

Hence, we have to prove the surjection of \( H^0((K + (2n - 2)B)|_{X_1}) \otimes H^0((K + B)|_{X_1}) \to H^0((2K + (2n - 1)B)|_{X_1}). \)

Application of Lemma 1.6 shows us it is enough to check the following inequality:

\[
\text{h}^1((2n-3)B|_{X_1}) \leq \text{h}^0((K + B)|_{X_1}) - 2 \quad (3.2.1)
\]

We have the short exact sequence:

\[
0 \longrightarrow (-K - B)|_{X_2} \longrightarrow \mathcal{O}_{X_2} \longrightarrow \mathcal{O}_{X_1} \longrightarrow 0
\]

Tensoring this by \((2n - 3)B\) gives:

\[
0 \longrightarrow (-K + (2n - 4)B)|_{X_2} \longrightarrow (2n - 3)B|_{X_2} \longrightarrow (2n - 3)B|_{X_1} \longrightarrow 0
\]

Consequently, we have the long exact sequence:

\[
\ldots \longrightarrow H^1((2n-3)B|_{X_2}) \longrightarrow H^1((2n-3)B|_{X_1}) \longrightarrow H^2((-K + (2n - 4)B)|_{X_2}) \longrightarrow \ldots
\]

Since \( H^1((2n-3)B|_{X_2}) = 0 \) by (i), we get \( \text{h}^1((2n-3)B|_{X_1}) \leq \text{h}^2((-K + (2n - 4)B)|_{X_1}). \)

Now, we have \( \text{h}^2((-K + (2n - 4)B)|_{X_1}) = \text{h}^0(((n-1)K + (n-2)B + K - (2n - 4)B)|_{X_1}) = \text{h}^0((K + (n-1)K - (n-2)B)|_{X_1}). \)

Note that, assumption (c) gives us \( \text{h}^0((K + (n-1)K - (n-2)B)|_{X_2}) \leq \text{h}^0(K|_{X_2}). \)

The long exact sequence associated to the following short exact sequence

\[
0 \longrightarrow (-B)|_{X_n-j+1} \longrightarrow K|_{X_n-j+1} \longrightarrow K|_{X_n-j} \longrightarrow 0
\]

shows us (by Kodaira Vanishing) that \( \text{h}^0(K|_{X_n-j}) = \text{h}^0(K|_{X_n-j+1}) \) for all \( 0 \leq j \leq n - 2 \).

Consequently we get that \( \text{h}^0(K|_{X_j}) = \text{h}^0(K). \)

So in order to show \( (3.2.1) \) it is enough to show \( \text{h}^0(K) \leq \text{h}^0((K + B)|_{X_1}) - 2 \) which comes from assumption (b).

**Lemma 3.3.** Let \( X \) be a regular \( n \) fold, \( n \geq 3 \). Let \( B \) be an ample and base point free line bundle on \( X \). We further assume:

(a) \( K \) is nef, \( K + B \) is base point free.

(b) \( \text{h}^0(B) \geq n + 2. \)

(c) \( \text{h}^0(K + B) \geq \text{h}^0(K) + n + 1. \)

(d) \( (n - 2)B - (n - 1)K \) is nef and non-zero effective divisor.

Let \( X_0 \) be \( X \), \( X_{n-j} \) is sufficiently general smooth irreducible \((n-j)\) fold chosen from the complete linear system of \( |B|_{X_{n-j+1}} \) for all \( 1 \leq j \leq n - 1 \). Let \( L \) be \( K + lB \) where \( l \geq n. \)

Then \( \text{h}^0(M_{l|X_{n-j}} \otimes L|_{X_{n-j}}) \otimes \text{h}^0(B|_{X_{n-j}}) \to \text{h}^0(M_{l|X_{n-j}} \otimes L|_{X_{n-j}} \otimes B|_{X_{n-j}}) \) surjects for all \( 0 \leq j \leq n - 1. \)
We have that the base point free line bundle $B$. In order to prove (3.3.1), it is enough to prove where $H$. We have that $B^n = \deg(f) \deg(Y)$ where $Y$ is the scheme theoretic image. Now, the codimension of $Y$ in $\mathbb{P}^r \geq 1$ and hence $\deg(Y) \geq 2$. So the only way $B^n < 4$ is when the following happens.

**Case 1**: $\deg(f) = 1$ and $\deg(Y) = 2$ and hence $\text{codim}(Y) = 1$

In this case we have that $Y$ is a variety of minimal degree and it is either a smooth quadric hypersurface or a cone over a smooth rational normal scroll or a cone over the veronese embedding of $\mathbb{P}^2$. Now in all three cases $Y$ is normal. Indeed, the first case is trivial. The second and third case follows from the fact that a cone over a projectively normal embedding is normal. Now $f$ is a finite birational map between normal varieties and is hence an isomorphism. Consequently, the image is a smooth rational normal scroll whose canonical is negative ample.

**Case 2**: $\deg(f) = 1$ and $\deg(Y) = 3$ and $\text{codim}(Y) = 2$

In this case again $Y$ is a variety of minimal degree and hence a normal variety and we have that $f$ is an isomorphism which leads to a contradiction as before.

**Case 3**: $\deg(f) = 1$ and $\deg(Y) = 3$ and $\text{codim}(Y) = 1$

In this case consider the general curve section $C$ of $|B|$ in $X$. It is the pullback of a general curve section $D$ of $\mathcal{O}(1)$ in $Y$. By Bertini we have that $C$ can be taken to be smooth and irreducible and since $f$ is surjective we have that $D$ is reduced and irreducible. Again $D$ is a plane curve of degree 3 and hence we have that $p_a(D) = 1$. $C$ is the normalization of $D$ and hence $g(C) \leq 1$. But we have that $2g(C) - 2 = (n - 1)B^n + B^{n-1}K_X$ and hence $g(C) \geq 4$ since $B^n = 3$ and $n \geq 3$. So we have a contradiction.

Now we start our induction.

**Induction Step**: Suppose $H^0(M_{L_{|X_{n-j}}} \otimes L_{|X_{n-j}}) \otimes H^0(B_{|X_{n-j}}) \to H^0(M_{L_{|X_{n-j}}} \otimes L_{|X_{n-j}} \otimes B_{|X_{n-j}})$ surjects for some $1 \leq j \leq n-1$. Then $H^0(M_{L_{|X_{n-j+1}}} \otimes L_{|X_{n-j+1}} \otimes H^0(B_{|X_{n-j+1}}) \to H^0(M_{L_{|X_{n-j+1}}} \otimes L_{|X_{n-j+1}} \otimes B_{|X_{n-j+1}})$ surjects.

First we prove $H^1(M_{L_{|X_{n-j+1}}} \otimes L_{|X_{n-j+1}} \otimes (B_{|X_{n-j+1}})^*) = 0$ \hspace{1cm} (3.3.1).

We have the short exact sequence:

$$0 \longrightarrow M_{L_{|X_{n-j+1}}} \otimes L'_{|X_{n-j+1}} \longrightarrow H^0(L_{|X_{n-j+1}}) \otimes L'_{|X_{n-j+1}} \longrightarrow (L + L')_{|X_{n-j+1}} \longrightarrow 0$$

where $L' = K + (n - 1)B$.

In order to prove (3.3.1) it is enough to prove $H^0(L_{|X_{n-j+1}}) \otimes H^0(L'_{|X_{n-j+1}}) \to H^0((L + L')_{|X_{n-j+1}})$ surjects since according to Lemma 2.1 (i) $H^1(L'_{|X_{n-j+1}}) = 0$.

To prove this surjection with the help of Observation 1.2, we need to prove the following:

(3.3.2) $H^0((K + lB)_{|X_{n-j+1}}) \otimes H^0(B_{|X_{n-j+1}}) \to H^0((L + (l + 1)B)_{|X_{n-j+1}})$ surjects for all $l > n$.

(3.3.3) $H^0((K + nB)_{|X_{n-j+1}}) \otimes H^0(B_{|X_{n-j+1}}) \to H^0((L + (n + 1)B)_{|X_{n-j+1}})$ surjects.

(3.3.4) $H^0((K + (2n - 2)B)_{|X_{n-j+1}}) \otimes H^0((K + B)_{|X_{n-j+1}}) \to H^0((2K + (2n - 1)B)_{|X_{n-j+1}})$ surjects.
We use CM Lemma (Lemma 1.7) to prove (3.3.2). Recall that $K_{X_{n-j+1}} = (K + (j-1)B)|_{X_{n-j+1}}$. Hence by Kodaira vanishing, $H^i((K+(l-i)B)|_{X_{n-j}}) = H^i((K+(j-1)B)|_{X_{n-j+1}} + ((l-i-j+1)B)|_{X_{n-j+1}}) = 0$ for all $1 \leq i \leq n-j+1$.

We have already proved (3.3.3) in Lemma 3.1.

For simplicity we do some re-indexing to prove (3.3.4) only. We will show that $H^0((K + (2n-2)B)|_{X_{n-j}}) \otimes H^0((K + B)|_{X_{n-j}}) \to H^0((2K + (2n-1)B)|_{X_{n-j}})$ surjects for all $0 \leq j \leq n-2$.

We have already proved the surjection when $j = 0$ in Lemma 3.2. So, we assume $1 \leq j \leq n-2$.

Our obvious choice is to use the CM Lemma (Lemma 1.7). For all $1 \leq i \leq n-j-1$, $H^i(((1-i)K+(2n-2-2i)B)|_{X_{n-j}}) = H^i((K+jB+(2n-2-2i-j)B+i(B-K))|_{X_{n-j}}) = 0$ as $B - K$ is nef and $2n - 2 - 2i - j > 0$ for $i$ in the given range.

$h^{n-j-1}((n + j - 2)B - (n - j - 1)K)|_{X_{n-j}} \cong H^0(((n - 1)K - (n - 2)B - (j - 1)K)|_{X_{n-j}}).

Now, $(n - 1)K - (n - 2)B - (j - 1)K |_{X_{n-j}}$ is negative nef and $(n - 1)K - (n - 2)B$ is negative of a non-zero effective divisor and consequently $h^{n-j-1}((n + j - 2)B - (n - j - 1)K)|_{X_{n-j}} = 0$.

Since we have proved (3.3.1) using Observation 1.2, it is enough to prove $H^0(M_{L_{X_{n-j+1}} \otimes L}|_{X_{n-j+1}} \otimes O_{X_{n-j}}) \otimes H^0(B|_{X_{n-j+1}} \otimes O_{X_{n-j}}) \to H^0(M_{L_{X_{n-j+1}} \otimes L}|_{X_{n-j+1}} \otimes B|_{X_{n-j+1}} \otimes O_{X_{n-j}})$ surjects for all $1 \leq j \leq n-1$.

Now we use the vector bundle technique (Lemma 1.5) by taking $F = L|_{X_{n-j+1}}$, $R = L|_{X_{n-j+1}}$, $Q = O_{X_{n-j+1}}(B|_{X_{n-j+1}})$, $r = 1$, $G = B|_{X_{n-j+1}}$.

We need to show the following:

(3.3.5) $H^1(F \otimes Q^r) = 0$ which comes from Lemma 2.1 (i).

(3.3.6) $H^0(M_{L_{X_{n-j+1}} \otimes L}|_{X_{n-j+1}}) \otimes H^0(B|_{X_{n-j+1}}) \to H^0(M_{L_{X_{n-j+1}} \otimes L}|_{X_{n-j+1}} \otimes B|_{X_{n-j+1}})$ surjects which is our induction hypothesis.

(3.3.7) $H^0(L|_{X_{n-j+1}}) \otimes H^0(B|_{X_{n-j+1}}) \to H^0((L + B)|_{X_{n-j+1}})$ surjects which comes from Lemma 3.1.

**Base Case:** We have to prove $H^0(M_{L_{X_1}} \otimes L|_{X_1}) \otimes H^0(B|_{X_1}) \to H^0(M_{L_{X_1}} \otimes L|_{X_1} \otimes B|_{X_1})$ surjects.

Now, $\text{deg}(L|_{X_1}) = (K + nB).B^{n-1}$.

$2g - 2 = (B|_{X_1})^2 + (B|_{X_1}).K_{X_2} = B^n + (K + (n - 2)B)B^{n-1}$ where $g = p_g(X_1)$.

$\implies \text{deg}(L|_{X_1}) > 2g$, thanks to $B^n > 2$.

$\implies M_{L_{X_1}}$ is semistable and $\mu(M_{L_{X_1}}) > -2$ (see [3]).

We will use Proposition 1.4 to prove this.

We need to check the following:

(3.3.8) $\mu(M_{L_{X_1}} \otimes L|_{X_1}) > 2g$.

(3.3.9) $\mu(M_{L_{X_1}} \otimes L|_{X_1}) > 4g - \text{deg}(B|_{X_1}) - 2h^1(B|_{X_1})$.

To prove (3.3.8) we have to show $(K + nB).B^{n-1} - 2 \geq B^n + B^{n-1}(K + (n - 2)B) + 2$ which follows since $B^n \geq 4$.

Showing (3.3.9) is equivalent to proving $2h^1(B|_{X_1}) \geq (n - 3)B^n + B^{n-1}K + 6$.

Riemann-Roch gives us $2h^1(B|_{X_1}) = 2h^0(B|_{X_1}) + (n - 3)B^n + B^{n-1}K$.

We are done since $h^0(B|_{X_1}) \geq n + 2$. ■
These three lemmas will help us proving the normal presentation of adjunction bundles associated to an ample, globally generated line bundle on a regular variety under suitable conditions.

**Theorem 3.4.** Let $X$ be a regular $n$ fold, $n \geq 3$. Let $B$ be an ample and base point free line bundle on $X$. We further assume:

(a) $K$ is nef, $K + B$ is base point free.
(b) $h^0(B) \geq n + 2$.
(c) $h^0(K + B) \geq h^0(K) + n + 1$.
(d) $(n - 2)B - (n - 1)K$ is nef and non-zero effective divisor.

Then $K + lB$ will satisfy the property $N_l$ for $l \geq n$.

**Proof.** We prove the assertion only for $l = n$. Let $L = K + nB$.

Since we already know that $H^1(M_L \otimes L) = 0$ which comes from the projective normality of $L$, we only have to prove for all $k \geq 1,$

\[ H^1(M_L^{k2} \otimes L^k) = 0. \]  \hspace{1cm} (3.4.1)

We omit the proof when $k \geq 2$ which follows easily from CM Lemma (Lemma 1.7). Here we only prove the key case that is $H^1(M_L^{2} \otimes L) = 0$.

We have the short exact sequence:

\[
0 \longrightarrow M_L^{2} \otimes L \longrightarrow H^0(L) \otimes M_L \otimes L \longrightarrow M_L \otimes L^2 \longrightarrow 0
\]

It is enough to prove that $H^0(L) \otimes H^0(M_L \otimes L) \rightarrow H^0(M_L \otimes L^2)$ surjects as $H^1(M_L \otimes L) = 0$.

We use Observation of [1.2], it is enough to prove the following:

(3.4.2) $H^0(M_L \otimes L) \otimes H^0(B) \rightarrow H^0(M_L \otimes L \otimes B)$ surjects.

(3.4.3) $H^0(M_L \otimes L) \otimes H^0(lB) \rightarrow H^0(M_L \otimes L \otimes lB)$ surjects for all $l \geq 2$.

(3.4.4) $H^0(M_L \otimes (K + (2n - 1)B)) \otimes H^0(K + B) \rightarrow H^0(M_L \otimes (2K + 2nB))$ surjects.

We have proved (3.4.2) in Lemma 3.3.

In order to prove (3.4.3) we again use Observation 1.2.

Therefore it is enough to prove that $H^0(M_L \otimes (K + lB)) \otimes H^0(B) \rightarrow H^0(M_L \otimes (K + (l + 1)B)$ surjects for $l > n$.

To prove this our obvious choice is to use CM lemma (Lemma 1.7).

First, we want to show that $H^1(M_L \otimes (K + (l - 1)B)) = 0$ which is equivalent to showing the surjection of the following:

\[ H^0(L) \otimes H^0(K + (l - 1)B) \rightarrow H^0(L + K + (l - 1)B). \]  \hspace{1cm} (3.4.5)

If $l = n + 1$ the this has already been proved in Theorem 2.3, Step 7.

If $l > n + 1$ then in order to show the surjection of (3.4.5) it is enough to prove

\[ H^0(2K + 2nB + rB) \otimes H^0(B) \rightarrow H^0(2K + 2nB + (r + 1)B) \]

surjects for all $r \geq 0$.

This is Step 1 in Theorem 2.3 with $k = 2$.

Now we will show that $H^i(M_L \otimes (K + (l - i)B)) = 0$ for all $2 \leq i \leq n$.

We have the short exact sequence:

\[
0 \longrightarrow M_L \otimes (K + (l - i)B) \longrightarrow H^0(L) \otimes (K + (l - i)B) \longrightarrow 2K + (l + n - i)B \longrightarrow 0
\]
It gives us the long exact sequence:

\[ \cdots \longrightarrow H^{i-1}(2K + (l + n - i)B) \longrightarrow H^i(M_L \otimes (K + (l - i)B)) \longrightarrow H^0(L) \otimes H^1(K + (l - i)B) \longrightarrow \cdots \]

Since the first and the last terms are zero by Kodaira vanishing, hence \( H^i(M_L \otimes (K + (l - i)B)) = 0 \) for all \( 2 \leq i \leq n \).

We are left to prove (3.4.4). Again we are going to use CM Lemma (Lemma 1.7).

We have to prove the following:

1. (3.4.6) \( H^1(M_L \otimes (2n - 2)B) = 0 \).
2. (3.4.7) \( H^j(M_L \otimes ((2n - 1 - j)B - (j - 1)K)) = 0 \) for all \( 2 \leq j \leq n - 1 \).
3. (3.4.8) \( H^n(M_L \otimes ((n - 1)B - (n - 1)K)) = 0 \).

We observe that (3.4.6) is equivalent to showing \( H^0(L) \otimes H^0((2n - 2)B) \rightarrow H^0(L + (2n - 2)B) \) surjects.

Using Observation 1.2 this is equivalent to showing \( H^0(K + lB) \otimes H^0(B) \rightarrow H^0(K + (l + 1)B) \) for all \( l \geq n \).

This follows from Lemma 2.4 and Theorem 2.3 Step 4.

To prove (3.4.7) we write down the short exact sequence:

\[ 0 \longrightarrow M_L \otimes (a_jB - b_jK) \longrightarrow H^0(L) \otimes (a_jB - b_jK) \longrightarrow L \otimes (a_jB - b_jK) \longrightarrow 0 \quad (3.4.9) \]

Where \( a_j = 2n - 1 - j \), \( b_j = j - 1 \).

The long exact sequence corresponding to it is:

\[ \cdots \longrightarrow H^{j-1}(L \otimes (a_jB - b_jK)) \longrightarrow H^j(M_L \otimes (a_jB - b_jK)) \longrightarrow H^0(L) \otimes H^1(a_jB - b_jK) \longrightarrow \cdots \]

Now \( H^{j-1}(L \otimes (a_jB - b_jK)) = H^{j-1}(K + (3n - 2j)B + (j - 1)B - K)) = 0 \) as \( 3n - 2j > 0 \) for all \( j < n \) and \( B - K \) is nef.

Also, \( H^j(a_jB - b_jK) = H^j(K + (2n - 2j - 1)B + (j - 1)B - K)) = 0 \) as \( 2n - 2j - 1 > 0 \) for all \( j < n \) and \( B - K \) is nef.

We are left to prove (3.4.8) only.

The long exact sequence associated to (3.4.9) corresponding to \( j = n \) is gives the required vanishing for the following reasons:

\[ H^{n-1}((2n - 1)B - (n - 2)K) = H^{n-1}(K + nB + (n - 1)B - K)) = 0. \]

Also, \( H^0((n - 1)(B - K)) \equiv H^0((n - 1)B - (n - 2)K) - K - (n - 2)B \) negative effective and \( K - B \) negative nef.

Now we prove a weaker result for the normal presentation of the adjunction bundle associated to an ample, globally generated line bundle on an irregular variety of dimension \( n \). Here we have to use Skoda complex to restrict ourselves to the multiplication map on the curve section as the variety is not regular. We include only a sketch of the proof as it is very similar to what we have done thus far.

**Theorem 3.5.** Let \( X \) be an irregular variety of dimension \( n \), \( n \geq 3 \). Let \( B \) be an ample and base point free line bundle on \( X \). We further assume:

(a) \( K \) is nef, \( B' \) and \( K + B' \) is base point free whenever \( B \equiv B' \).
(b) \( h^0(B) \geq n + 2 \).
(c) $h^0(K + B) \geq h^0(K') + n + 1$ whenever $K \equiv K'$.

(d) $(n-2)B - (n-1)K$ is nef and non-zero effective divisor.

Then $K + lB$ will satisfy the property $N_l$ for $l \geq n$.

**Proof.** As before, we just give the sketch for $L = K + nB$. We have to prove the vanishing $H^1(M_L \otimes L^k) = 0$. Again, we just discuss the case when $k = 1$.

It is enough to prove the surjection of $H^0(M_L \otimes L) \otimes H^0(L) \to H^0(M_L \otimes L^2)$.

Let $E$ be a torsion line bundle in $Pic^0(X)$ which is not $n$ torsion. Such an $E$ exists as $Pic^0(X)$ is an abelian variety when $X$ is irregular.

Observation [1.2] tells us it is enough to check the following three surjection:

(3.5.1) $H^0(M_L \otimes (K + nB)) \otimes H^0(B + E) \to H^0(M_L \otimes ((n+1)B + E))$. Note that $B + E$ is globally generated by assumption (a).

(3.5.2) $H^0(M_L \otimes (K + rB + E)) \otimes H^0(B) \to H^0(M_L \otimes ((r+1)B + E)$ for $n + 1 \leq r \leq 2n - 2$.

(3.5.3) $H^0(M_L \otimes (K + (2n-1)B + E)) \otimes H^0(K + B - E) \to H^0(M_L \otimes (2K + 2nB))$.

To show (3.5.1) we use CM Lemma (Lemma [1.7]). We have to prove $H^1(M_L \otimes (K + nB - iB - iE) = 0$ for all $1 \leq i \leq n$.

When $2 \leq i \leq n - 1$ this follows easily by multiplying the exact sequence [4] by suitable line bundle and then taking the cohomology.

When $i = n$, doing the same thing shows the vanishing once we see that $H^0(nE) = 0$.

To prove the vanishing for $i = 1$, we need to show the surjection of $H^0(L) \otimes H^0(K + (n-1)B - E) \to H^0(2K + (2n-1)B - E)$.

By Observation [1.2], Lemma [2.1] and Theorem [2.3] Step [4] it is enough to prove the surjection of $H^0(K + (2n-2)B) \otimes H^0(K + B - E) \to H^0(2K + (2n-1)B - E)$.

Now, $K + B - E$ is base point free by our assumption. Let $C$ be a curve section of $K + B - E$.

Using Skoda complex (Definition [1.8] and Lemma [1.6] it is enough to check $h^1(((2n-3)B + E)|_C) \leq h^0(K + B) - (n + 1)$.

Now, $h^1(((2n-3)B + E)|_C) = h^0((nK - (n-2)B - nE)|_C) = h^0(nK - (n-2)B - nE) \leq h^0(K - nE)$ thanks to assumption (d).

So, the inequality follows thanks to assumption (c).

(3.5.2) and (3.5.3) follows from CM Lemma (Lemma [1.7]) as well. ■

**Remark 3.5.1.** We always have $h^0(K + B) \geq h^0(K') + n$ on any $n$ fold if $K + B$, $K' + B$, $B$ are ample, base point free and $K \equiv K'$.

**Proof:** We have $K' = K + \delta$ where $\delta$ is a numerically trivial line bundle.

By Riemann-Roch, $h^0(K + B) = h^0(K + B + \delta)$. The assertion follows from an argument similar to the proof of Remark [2.2.1].

4. **Properties $N_0$ and $N_1$ for Pluricanonical Series on Three and Four-Folds**

In this section, we will concentrate on the behavior of pluricanonical series. First, we will prove a theorem whose corollaries will give us effective results on three and four folds. We again work on smooth varieties only.

**Theorem 4.1.** Let $X$ be an $n$ dimensional variety and Let $B$ be an ample, globally generated line bundle on $X$. Let $L$ be a nef line bundle on $X$. Moreover, assume:

(a) $(n - 1)(B - L) - K$ is ample.
(b) $B - K$ is ample.
(c) $B + L$ is globally generated.
(d) $h^0(K - L) \leq h^0(B) - (n + 1)$.

Then $nB + L$ will be very ample and it will embed $X$ as a projectively normal variety.

**Proof.** Let $X_n$ be $X$, $X_{n-j}$ be a smooth irreducible $(n - j)$ fold chosen from the complete linear system of $|B|_{x_{n-j+1}}$ by Bertini, for all $1 \leq j \leq n - 1$.

By adjunction, $K_{x_{n-j}} = (K + jB)|_{x_{n-j}}$ for all $0 \leq j \leq n - 1$.

We have to prove $H^0((k(nB + L)) \otimes H^0(nB + L) \to H^0((k + 1)(nB + L))$ surjects. Here we show the key case that is the case when $k = 1$. We break the proof into a few steps.

**Step 1:** $H^0(nB + L) \otimes H^0(B) \to H^0((n + 1)B + L)$ surjects.

We have the following situation (4.1.1) where $\mathcal{I}$ is the sheaf of $X_1$ in $X$, $V$ is the cokernel of $H^0(B) \to H^0(B)$:

$0 \to H^0(nB + L) \otimes H^0(B) \to H^0(nB + L) \otimes V \to 0$

$0 \to H^0((n + 1)B + L) \otimes \mathcal{I} \to H^0((n + 1)B + L) \to 0$

Note that $H^0((rB + L)|_{x_{n-j}}) \to H^0((rB + L)|_{x_{n-j-1}})$ surjects for all $0 \leq j \leq n - 2$, $r \geq n$ as $H^1((r - 1)B + L)|_{x_{n-j}} = 0$. Therefore the bottom horizontal sequence is exact. Note that the top row is exact as well. Consequently, tensoring the following exact sequence (4.1.2)

$0 \to \bigwedge^{n-1} W \otimes B^{-(n-1)} \to \cdots \to \bigwedge^2 W \otimes B^-2 \to W \otimes B^-1 \to \mathcal{I} \to 0$

by $(n + 1)B + L$, we get the following exact sequence where $L' = (n + 1)B + L$

$0 \to \bigwedge^{n-1} W \otimes L' \otimes B^{-(n-1)} \to \cdots \to \bigwedge^2 W \otimes L' \otimes B^-2 \to W \otimes L' \otimes B^-1 \to \mathcal{I} \to 0$

We need $H^1(\ker(f_j)) = 0$.

We have the required vanishing because of the following:

**Fact 1:** $H^1(\ker(f_j)) = 0 \implies H^{j-1}(\ker(f_{j-1})) = 0$ for all $2 \leq j \leq n - 2$.

**Fact 2:** $\text{H}^{n-2}(L' - (n - 1)B) = 0$.

By Lemma 1.6, it is enough to prove the inequality $h^1((n - 1)B + L)|_{x_{n-j}} \leq h^0(B) - (n + 1)$.

But $h^1((n - 1)B + L)|_{x_{n-j}} = h^0((K - L)|_{x_{n-j}}) = h^0(K - L)$ which proves the assertion because of our assumption (d).

**Step 2:** $H^0(rB + L) \otimes H^0(B) \to H^0((r + 1)B + L)$ surjects for all $r \geq n + 1$.

This comes from CM Lemma (Lemma 1.7).

**Step 3:** $H^0((2n - 1)B + L) \otimes H^0(B + L) \to H^0(2nB + 2L)$ surjects.

This comes from CM Lemma (Lemma 1.7) as well thanks to assumption (a). ■

**Corollary 4.2.** Let $X$ be an $n$ dimensional variety, $n \geq 3$, with ample canonical sheaf $K$. We further assume that $IK$ is globally generated for all $l \geq n + 2$. Then the following will hold:

(i) If $h^0(K) \leq h^0((n + 2)K) - (n + 1)$ then $n(n + 2)K$ is very ample and it embeds $X$ as a projectively normal variety.
(ii) If \( h^0((n+2)K) > n+1 \) then \((n(n+2)+1)K\) is very ample and it embeds \(X\) as a projectively normal variety.

(iii) \((n(n+2)+m)K\) is very ample and it embeds \(X\) as a projectively normal variety for all \(m \geq 2\).

Proof of (i), (ii). This follows directly from Theorem [4.1] with \(B = (n+2)K\) and \(L = 0\), \(K\) respectively.

Proof of (iii). Let \(s = n+2\). The proof is entirely based on CM Lemma (Lemma [1.7]). We give an outline here. We divide the proof into a few steps.

Step 1: \(H^0((ns + m)K) \otimes H^0(sK) \rightarrow H^0((n+1)s + m)K\) surjects for all \(m \geq 2\).
This comes from CM Lemma (Lemma [1.7]).

Step 2: \(H^0(((2n - 1)s + m)K) \otimes H^0((s + m)K) \rightarrow H^0((2ns + 2m)K)\) surjects for all \(m \geq 2\).
If \(m \geq s\), then \(m = as + b\) where \(a \geq 1\) and \(b < s\).
In that case, by Observation [1.2], it is enough to show \(H^0(((2ns + m + (a - 1)s)K) \otimes H^0((s + b)K) \rightarrow H^0((2ns + 2m)K)\) surjects for all \(m \geq 2\) which comes from CM Lemma (Lemma [1.7]).
If \(m < s\), we can directly use CM Lemma (Lemma [1.7]).

The above two steps shows the surjectivity of \(H^0((ns+m)K) \otimes H^0((ns+m)K) \rightarrow H^0((2ns+2m)K)\).
Similar calculation shows \(H^0(k(ns + m)K) \otimes H^0((ns + m)K) \rightarrow H^0((k + 1)(ns + m)K)\) surjects for all \(k \geq 2\).

Now we combine our results with the base point freeness theorems on three and four folds (see [7] and [20]). In particular, we will use Theorems [1.9] [1.11] and Corollary [1.10]

Corollary 4.3. Let \(X\) be a smooth projective threefold with ample canonical bundle \(K\). Then \(nK\) is very ample and embeds \(X\) as a projectively normal variety for all \(n \geq 12\).

Proof. We have by Riemann-Roch that \(\chi(D) + \chi(-D) = \frac{-K.D^2}{2} + 2\chi(\mathcal{O}_X)\).
Hence, \(K.D^2\) is even for any divisor \(D\). So in particular \(K^3\) is even. By Theorem [1.10] we have that \(4K\) is base point free.

By CM Lemma (Lemma [1.7]), we have that the corollary is obvious for \(n \geq 14\) since \(K\) is ample and we have Kodaira Vanishing.

For \(n = 13\) we use Theorem [4.1] with \(L = K\). Conditions (a), (b), (c) are easily satisfied. We need to check that \(h^0(4K) \geq 5\). We note that by Riemann-Roch and [1.12], we have \(h^0(4K) \geq 6 + h^0(2K)\) and hence we are done.

For the case \(n = 12\) we again apply Theorem [4.1] but now with \(L = 0\). Here we need to check the fact that \(h^0(4K) \geq h^0(K) + 4\). If \(h^0(K) = 0\) then we are done trivially since \(4K\) is ample and base point free. If not then we know that \(K\) is effective and hence \(h^0(K) \leq h^0(2K)\).
So the required inequality comes from the inequality \(h^0(4K) \geq 6 + h^0(2K)\).

Corollary 4.4. Let \(X\) be a smooth projective threefold with ample canonical bundle \(K\) we have that the embedding by \(nK\) for \(n \geq 13\) is normally presented.

Proof. Suppose that \(L = nK\). We note that the cases \(n = 3l + 1\) with \(l \geq 4\) normal presentation of \(nK\) directly follows from Riemann-Roch and Theorem [3.4] for regular threefolds and [3.5] for irregular threefolds using \(B = lK\) respectively. While using Theorem [3.5] we need to check the conditions. We only check the conditions (a) and (c) below.
(a) We have $B = lK, l \geq 4$. Suppose $B' \equiv B$, then we have that $B' - K$ is ample and $(B' - K)^3 > 27$ (using $K^3 \geq 2$) and $(B' - K).C \geq 3$ and $(B' - K)^2.S \geq 9$ for any curve $C$ and surface $S$ respectively. Hence $B'$ is base point free by Theorem 1.9. Similar reasoning will show that $K + B'$ is base point free as well.

(b) Since $K + B$ is ample and base point free, if $h^0(K') = 0$ we are done. Otherwise $K'$ is effective and $h^0(K') \leq h^0(2K')$. Note that $h^0(4K) \leq h^0((l + 1)K)$. But since all higher cohomology of $2K'$ vanishes by Kodaira Vanishing we have that by Riemann Roch $h^0(2K')$ depends only on the numerical class of $K'$ and hence $h^0(2K) = h^0(2K')$. So it is enough to show that $h^0(4K) - h^0(2K) \geq 4$ which we have shown in the proof of corollary 4.3 (in fact shown $\geq 6$).

For other cases, it is enough to show that $H^1(M_L^{62} \otimes L^{64}) = 0$ since we have already shown projective normality for $nK$ for $n \geq 13$. We only show the case $k = 1$ since for $k \geq 2$ the proof follows from CM Lemma (Lemma 7). We have the following exact sequence

$$0 \longrightarrow M_L^{62} \otimes L \longrightarrow H^0(L) \otimes M_L \otimes L \longrightarrow M_L \otimes L^{62} \longrightarrow 0$$

Taking cohomology we have the following

$$... \longrightarrow H^0(L) \otimes H^0(M_L \otimes L) \longrightarrow H^0(M_L \otimes L^{62}) \longrightarrow H^1(M_L^{62} \otimes L) \longrightarrow ...$$

It is enough to show that $H^0(L) \otimes H^0(M_L \otimes L) \longrightarrow H^0(M_L \otimes L^{62})$ is surjective. Now $4K$ is base point free. We first show that $H^0(M_L \otimes L) \otimes H^0(4K) \longrightarrow H^0(M_L \otimes L + 4K)$ is surjective. To do this it is enough to show (by Lemma 1.7) the following:

(i) $H^1(M_L \otimes L - 4K) = 0$
(ii) $H^2(M_L \otimes L - 8K) = 0$
(iii) $H^3(M_L \otimes L - 12K) = 0$

Now $L = nK$ with $n \geq 14$ (the case when $L = 13K$ has already been taken care of). By tensoring the exact sequence

$$0 \longrightarrow M_L \longrightarrow H^0(L) \otimes \mathcal{O}_X \longrightarrow L \longrightarrow 0$$

by $L - 8K$ and $L - 12K$ respectively and using Kodaira vanishing theorem we can see that (ii) and (iii) follow immediately. Now we note that to show (i) we need to to show that $H^0(L) \otimes H^0(L - 4K) \longrightarrow H^0(2L - 4K)$ is surjective.

We now note that $L - 4K = mK$ where $m \geq 10$. Using observation 1.2 we show surjectivity of multiplication maps by $H^0(4K)$ where until we are left with $lK$ where $0 \leq l \leq 7$. Hence $H^0(L) \otimes H^0(L - 4K) \longrightarrow H^0(2L - 4K)$ is surjective for $L = nK$ and $n \geq 19$. We need to check separately from $14 \leq n \leq 18$.

Case $n=14$. We need to show the surjectivity of $H^0(14K) \otimes H^0(10K) \rightarrow H^0(24K)$.
We have by Lemma 1.7 the surjectivity of $H^0(14K) \otimes H^0(4K) \rightarrow H^0(18K)$.
We have the surjectivity of $H^0(18K) \otimes H^0(6K) \rightarrow H^0(24K)$ using Step 1, Theorem 4.1 with $B = 6K$ and $L = 0$.

Case $n=15$. We need to show the surjectivity of $H^0(15K) \otimes H^0(11K) \rightarrow H^0(26K)$.
We have that $H^0(15K) \otimes H^0(5K) \rightarrow H^0(20K)$ surjects by Theorem 4.1 with $B = 5K$ and $L = 0$.
We have the surjectivity of $H^0(20K) \otimes H^0(6K) \rightarrow H^0(26K)$ by Lemma 1.7.

Case $n=17$. We need to show the surjectivity of $H^0(17K) \otimes H^0(13K) \rightarrow H^0(30K)$.
This case is easy and follows from Lemma 1.7.
Case $n=18$. We need to show the surjectivity of $H^0(18K) \otimes H^0(14K) \to H^0(32K)$. This case follows directly from Lemma 1.7.

The algorithmic nature of the proof shows that we have actually proved the surjectivity of the map $H^0(M_L \otimes (L + 4lK)) \otimes H^0(4K) \to H^0(M_L \otimes (L + 4(l + 1)K))$. Since $L = nK$ where $n \geq 14$, to complete the proof we just need to prove the surjection of $H^0(M_L \otimes (L + 4lK)) \otimes H^0(pK) \to H^0(M_L \otimes (L + (4l + p)K))$ where $l \geq 2$ and $p \leq 7$.

Moreover if $n \geq 16$ we have that $l \geq 3$. So for $n \geq 16$, using Lemma 1.7 we see that it is enough to prove the surjection of $H^0(L + mK) \otimes H^0(L) \to H^0(2L + mK)$ where $m \geq 5$. But we have the surjection of $H^0(L) \otimes H^0(L) \to H^0(2L)$.

So, using Observation 1.2 we only need to prove the surjection of $H^0(lK) \otimes H^0(mK) \to H^0((m+l)K)$ where $l \geq 3$. Since $4K$ is base point free, we have the above surjection by Lemma 1.7 and Observation 1.2.

To finish the proof we need to handle the two following cases separately.

$L=14K$. We need to show the surjection of $H^0(M_L \otimes (L + 8K)) \otimes H^0(6K) \to H^0(M_L \otimes (L + 14K))$. By Lemma 1.7 we notice that it is enough to show the surjection of $H^0(16K) \otimes H^0(14K) \to H^0(30K)$ which is clear by the same lemma.

$L=15K$. We need to show the surjection of $H^0(M_L \otimes (L + 8K)) \otimes H^0(7K) \to H^0(M_L \otimes (L + 15K))$. By Lemma 1.7 we notice that it is enough to show the surjection of the following map $H^0(16K) \otimes H^0(15K) \to H^0(31K)$ which is again clear by the same lemma.

**Corollary 4.5.** Let $X$ be a smooth projective four dimensional variety with ample canonical bundle $K$. Then $nK$ is very ample and it will embed $X$ as a projectively normal variety for all $n \geq 24$.

*Proof.* This comes directly from Corollary 3.2. Riemann-Roch for a line bundle $B$ on a four folds is given by

$$
\chi(B) = \frac{-1}{720} (K^4 - 4K^2.c_2 - 3c_2^2 + K.c_3 + c_4) - \frac{1}{24} B.K.c_2 + \frac{1}{24} B^2.(K^2 + c_2) - \frac{1}{12} B^3.K + \frac{1}{24} B^4.
$$

It is enough to show that $h^0(2K) \leq h^0(6K) - 5$ which can be seen easily, thanks to the fact $K^2.c_2 \geq 0$ (see Remark 1.12.1). In fact, $h^0(2K) \leq h^0(6K) - 6$ which verifies condition (ii).

**Corollary 4.6.** Let $X$ be a smooth projective 4-fold with ample canonical bundle $K$ we have that the embedding by $nK$ for $n \geq 25$ is normally presented.

*Proof.* We use the same argument as in Corollary 4.5 but now using the fact that $6K$ is globally generated (see Theorem 1.11).

**Corollary 4.7.** Let $X$ be a smooth projective 5-fold with ample canonical bundle $K$ with an additional property that $p_g(X) \geq 1$. Then the embedding by $nK$ for $n \geq 35$ is projectively normal and the embedding by $nK$ for $n \geq 36$ is normally presented.

*Proof.* We know that $nK$ is globally generated for $n \geq 7$ (see 35). Let $\mathcal{K}$ be a smooth divisor chosen from the linear system of $|K|$. The corollary follows once we note that $h^0(7K) - h^0(6K) = h^0(7K)|_{\mathcal{K}}$ and apply Riemann-Roch on $\mathcal{K}$ to verify conditions (i) and (ii) of Corollary 4.2. Normal Presentation follows from the similar arguments used before.
5. Appendix

Here we list some remarks. The first one modifies the ampleness of the base point free line bundle we used to prove projective normality in sections 2 and 3. The second and third remark discuss the case when the variety is singular.

Remark 5.1. We first note that in all the theorems 2.3, 3.4, 3.5 the criterion of the line bundle $B$ being ample and base point free can be weakened to $B$ being base point free, big and $dim f(X) = n$ where $n$ is the dimension of the variety. This is because we used the ample and base point freeness of $B$ to find a smooth and irreducible member of the complete series $|B|$, in applying the Kodaira vanishing theorem and to say that $h^0(B) \geq n + 1$. However the later conditions also ensure all the three (see [17], III Ex: 11.3) with Kodaira vanishing theorem replaced by the Kawamata-Viehwag vanishing theorem.

Remark 5.2. Now we note that the fact that the Theorems 2.3, 3.4, 3.5 and 4.1 goes through for $X$ normal, Cohen-Macaulay with Du Bois singularities. The precise reasons for which we require smoothness are the following:

We require smooth hyperplane sections of the ample and base point free line bundle $B$. The smoothness is used to justify Kodaira Vanishing (both on the general member of $|B|$ and on $X$) and to apply Green’s result (Lemma [1.6]) on the smooth curve section.

We observe that since $X$ is Cohen-Maculay and $B$ is cartier, the general member of $|B|$ is Cohen-Maculay as well. Also since $X$ is nonsingular in codimension 1 and $|B|$ is base point free, a general member of $|B|$ is smooth outside the singular locus of $X$ (by Bertini’s theorem) and is hence nonsingular in codimension 1. The above two observations show that the general member is normal. Now the general hyperplane section of $|B|$ also has Du Bois singularities (see [24], Proposition 6.20). We also have (see [24], Theorem 10.42) that for a projective, Cohen-Macaulay variety with Du Bois singularities we have the Kodaira Vanishing theorem for an ample line bundle. Now the complete intersection surface that we get is a normal surface and hence singularities are isolated. So Bertini’s Theorem gives us a smooth curve section and we can apply Lemma [1.6].

Now Kollár and Kovács proves that log canonical singularities are Du Bois (See [25]) and hence by Remark 5.2, we have that the results mentioned in Remark 5.2 goes through for log canonical singularities and hence in particular for $\mathbb{Q}$-factorial terminal Gorenstein and Canonical Gorenstein singularities. Oguiso-Peternell’s generalization of Ein-Lazarsfeld’s result on Fujita conjecture combined with Theorem 3.4, Theorem 3.5 and Theorem 4.1 gives the following.

Corollary 5.3. If $X$ is a projective threefold with $\mathbb{Q}$-factorial terminal Gorenstein singularities and ample canonical bundle $K$ then we have that $18K$ is projectively normal and $19K$ is normally presented.

Proof. By [29], Corollary 2.3, we have that $6K$ is base point free and hence the result follows by exact same argument as in Corollary 4.3 of this article provided we have the exact form of Riemann-Roch as on a smooth threefold. Now, by Theorem 10.2, [32], we have what we want since the Gorenstein assumption gives us that $6K$ is Cartier and hence we do not have any contribution due to the singularities of the sheaf $\mathcal{O}_X(6K)$.

Corollary 5.4. If $X$ is a projective threefold with canonical Gorenstein singularities and ample canonical bundle $K$ then we have that $24K$ is projectively normal and $25K$ is normally presented.
**Proof.** The result follows since $8K$ is base point free (see [29], Corollary 2.2).
