SPHERICAL NILPOTENT ORBITS IN POSITIVE CHARACTERISTIC

RUSSELL FOWLER AND GERHARD RÖHRLE

Abstract. Let $G$ be a connected reductive linear algebraic group defined over an algebraically closed field of characteristic $p$. Assume that $p$ is good for $G$. In this note we classify all the spherical nilpotent $G$-orbits in the Lie algebra of $G$. The classification is the same as in the characteristic zero case obtained by D.I. Panyushev in 1994, [32]: for $e$ a nilpotent element in the Lie algebra of $G$, the $G$-orbit $G \cdot e$ is spherical if and only if the height of $e$ is at most 3.

Let $G$ be a connected reductive linear algebraic group defined over an algebraically closed field $k$ of characteristic $p > 0$. With the exception of Subsection 4.5, we assume throughout that $p$ is good for $G$ (see Subsection 2.1 for a definition).

A spherical $G$-variety $X$ is an (irreducible) algebraic $G$-variety on which a Borel subgroup $B$ of $G$ acts with a dense orbit. Homogeneous spherical $G$-varieties $G/H$, for $H$ a closed subgroup of $G$, are of particular interest. They include flag varieties (when $H$ is a parabolic subgroup of $G$) as well as symmetric spaces (when $H$ is the fixed point subgroup of an involutive automorphism of $G$). We refer the reader to [5] and [6] for more information on spherical varieties and for their representation theoretic significance. These varieties enjoy a remarkable property: a Borel subgroup of $G$ acts on a spherical $G$-variety only with a finite number of orbits. This fundamental result is due to M. Brion [4] and É. B. Vinberg [49] independently in characteristic 0, and to F. Knop [25, 2.6] in arbitrary characteristic.

Let $\mathfrak{g} = \text{Lie} G$ be the Lie algebra of $G$. The aim of this note is to classify the spherical nilpotent $G$-orbits in $\mathfrak{g}$. In case $k$ is of characteristic zero, this classification was obtained by D.I. Panyushev in 1994 in [32]. The classification is the same in case the characteristic of $k$ is good for $G$: for $e \in \mathfrak{g}$ nilpotent, $G \cdot e$ is spherical if and only if the height of $e$ is at most 3 (Theorem 3.42). The height of $e$ is the highest degree in the grading of $\mathfrak{g}$ afforded by a cocharacter of $G$ associated to $e$ (Definition 2.26).

The methods employed by Panyushev in [32] do not apply in positive characteristic, e.g. parts of the argument are based on the concept of “stabilizers in general position”; it is unknown whether these exist generically in positive characteristic. Thus a different approach is needed to address the question in this case.

We briefly sketch the contents of the paper. In Section 2 we collect the preliminary results we require. In particular, we discuss the concepts of complexity and sphericity, and more specifically the question of complexity of homogeneous spaces. In Subsection 2.5 we recall the basic results of Kempf–Rousseau Theory and in Subsection 2.6 we recall the fundamental concepts of associated cocharacters for nilpotent elements from [22, §5] and [37]. There we also recall the grading of $\mathfrak{g}$ afforded by a cocharacter associated to a given nilpotent element and define the notion of the height of a nilpotent element as the highest occurring degree of such a grading, Definition 2.26. The complexity of fibre bundles is discussed in Subsection 2.7 which is crucial for the sequel. In particular, in Theorem 2.33 we show that the complexity of a fixed nilpotent orbit $G \cdot e$ is given by the complexity of a smaller reductive group acting on a linear space. Precisely, let $\lambda$ be a cocharacter of $G$ that is associated to $e$. Then $P_\lambda$ is the destabilizing parabolic subgroup $P(e)$ defined by $e$, in the sense of Geometric Invariant Theory. Moreover, $L = C_G(\lambda(\mathbb{k}^*))$ is a Levi subgroup of $P(e)$. We show in Theorem 2.33 that the complexity of $G \cdot e$ equals the complexity of the action of $L$ on the subalgebra $\bigoplus_{i \geq 2} \mathfrak{g}(i, \lambda)$ of $\mathfrak{g}$ where the grading $\mathfrak{g} = \bigoplus_{i \in \mathbb{Z}} \mathfrak{g}(i, \lambda)$ is afforded by $\lambda$. In Subsection 2.8 we recall the concept of a weighted Dynkin diagram associated to a nilpotent orbit from [10, §5]. There we also present the classification of the parabolic subgroups $P$ of a simple algebraic group $G$ admitting a dense action of a Borel subgroup of a Levi subgroup of $P$ on the unipotent radical of $P$ from [7, Thm. 4.1]. Here we also remind the reader of the classification of the parabolic subgroups of $G$ with an abelian unipotent radical.

In Section 3 we give the classification of the spherical nilpotent orbits in good characteristic: a nilpotent element $e$ in $\mathfrak{g}$ is spherical if and only if the height of $e$ is at most 3 (Theorem
In Subsections 3.1 and 3.3 we show that orbits of height 2 are spherical and orbits of height at least 4 are not, respectively. The subsequent subsections deal with the cases of height 3 nilpotent classes. For classical groups these only occur for the orthogonal groups. For the exceptional groups the height 3 cases are handled in Subsection 3.7 with the aid of a computer programme of S.M. Goodwin.

In Section 4 we discuss some further results and some applications of the classification. In Subsection 4.1 we discuss the spherical nilpotent orbits that are distinguished and in Subsection 4.2 we extend a result of Panyushev in characteristic zero to good positive characteristic: a characterization of the spherical nilpotent orbits in terms of pairwise orthogonal simple roots, see Theorem 4.14.

In Subsection 4.3 we discuss generalizations of results from [34] and [35] to positive characteristic. In Theorem 4.18 we show that if \( a \) is an abelian ideal of \( b \), then \( G \cdot a \) is a spherical variety. In Subsection 4.4 we describe a geometric characterization of spherical orbits in simple algebraic groups from [8] and [9]. Finally, in Subsection 4.5 we very briefly touch on the issue of spherical nilpotent orbits in bad characteristic.

Thanks to the fact that a Springer isomorphism between the unipotent variety of \( g \) and the nilpotent variety of \( g \) affords a bijection between the unipotent \( G \)-classes in \( G \) and the nilpotent \( G \)-orbits in \( g \) (cf. [45]), there is an analogous classification of the spherical unipotent conjugacy classes in \( G \).

For results on algebraic groups we refer the reader to Borel’s book [2] and for information on nilpotent classes we cite Jantzen’s monograph [22].

2. Preliminaries

2.1. Notation. Let \( H \) be a linear algebraic group defined over an algebraically closed field \( k \). We denote the Lie algebra of \( H \) by \( \text{Lie} \ H \) or by \( \mathfrak{h} \). We write \( H^\circ \) for the identity component of \( H \) and \( Z(H) \) for the centre of \( H \). The derived subgroup of \( H \) is denoted by \( DH \) and we write \( \text{rank} H \) for the dimension of a maximal torus of \( H \). The unipotent radical of \( H \) is denoted by \( R_u(H) \). We say that \( H \) is reductive provided \( H^\circ \) is reductive. Let \( K \) be a subgroup of \( H \). We write \( C_H(K) = \{ h \in H \mid h x h^{-1} = x \text{ for all } x \in K \} \) for the centralizer of \( K \) in \( H \).

Suppose \( H \) acts morphically on an algebraic variety \( X \). Then we say that \( X \) is an \( H \)-variety. Let \( x \in X \). Then \( H \cdot x \) denotes the \( H \)-orbit of \( x \) in \( X \) and \( C_H(x) = \{ h \in H \mid h \cdot x = x \text{ for all } h \in H \} \) is the stabilizer of \( x \) in \( H \).

For \( e \in \mathfrak{h} \) we denote the centralizers of \( e \) in \( H \) and \( \mathfrak{h} \) by \( C_H(e) = \{ h \in H \mid \text{Ad}(h)e = e \} \) and \( c_{\mathfrak{h}}(e) = \{ x \in \mathfrak{h} \mid [x, e] = 0 \} \), respectively. For \( S \) a subset of \( H \) we write \( c_{\mathfrak{h}}(S) = \{ x \in \mathfrak{h} \mid \text{Ad}(s)x = x \text{ for all } s \in S \} \) for the centralizer of \( S \) in \( \mathfrak{h} \).

Suppose \( G \) is a connected reductive algebraic group. By \( N \) we denote the nilpotent cone of \( g \). Let \( T \) be a maximal torus of \( G \). Let \( \Psi = \Psi(G, T) \) denote the set of roots of \( G \) with respect to \( T \). Fix a Borel subgroup \( B \) of \( G \) containing \( T \) and let \( \Pi = \Pi(G, T) \) be the set of simple roots of \( \Psi \) defined by \( B \). Then \( \Psi^+ = \Psi(B, T) \) is the set of positive roots of \( G \) with respect to \( B \). For \( I \subset \Pi \), we denote by \( P_I \) and \( L_I \) the standard parabolic and standard Levi subgroups of \( G \) defined by \( I \), respectively; see [10, §2].

For \( \beta \in \Psi^+ \) write \( \beta = \sum_{\alpha \in \Pi} c_{\alpha \beta} \alpha \) with \( c_{\alpha \beta} \in \mathbb{N}_0 \). A prime \( p \) is said to be good for \( G \) if it does not divide \( c_{\alpha \beta} \) for any \( \alpha \) and \( \beta \), [48, Defn. 4.1]. Let \( U = R_u(B) \) and set \( u = \text{Lie} \ U \). For a \( T \)-stable Lie subalgebra \( m \) of \( u \) we write \( \Psi(m) = \{ \beta \in \Psi^+ \mid g_{\beta} \subseteq m \} \) for the set of roots of \( m \) (with respect to \( T \)).
For every root $\beta \in \Psi$ we choose a generator $e_\beta$ for the corresponding root space $\mathfrak{g}_\beta$ of $\mathfrak{g}$. Any element $e \in \mathfrak{u}$ can be uniquely written as $e = \sum_{\beta \in \Psi^+} c_\beta e_\beta$, where $c_\beta \in k$. The support of $e$ is defined as $\text{supp}(e) = \{ \beta \in \Psi^+ \mid c_\beta \neq 0 \}$.

The variety of all Borel subgroups of $G$ is denoted by $\mathcal{B}$. Note that $\mathcal{B}$ is a single conjugacy class $\mathcal{B} = \{ B^g \mid g \in G \}$. Also note the isomorphism $\mathcal{B} \cong G / B$.

Let $Y(G) = \text{Hom}(k^*, G)$ denote the set of cocharacters (one-parameter subgroups) of $G$, likewise for a closed subgroup $H$ of $G$, we set $Y(H) = \text{Hom}(k^*, H)$ for the set of cocharacters of $H$. For $\lambda \in Y(G)$ and $g \in G$ we define $g \cdot \lambda \in Y(G)$ by $(g \cdot \lambda)(t) = g\lambda(t)g^{-1}$ for $t \in k^*$; this gives a left action of $G$ on $Y(G)$. For $\mu \in Y(G)$ we write $C_G(\mu)$ for the centralizer of $\mu$ under this action of $G$ which coincides with $C_G(\mu(k^*))$.

By a Levi subgroup of $G$ we mean a Levi subgroup of a parabolic subgroup of $G$. The Levi subgroups of $G$ are precisely the subgroups of $G$ which are of the form $C_G(S)$ where $S$ is a torus of $G$, [2, Thm. 20.4]. Note that for $S$ a torus of $G$ the group $C_G(S)$ is connected, [2, Cor. 11.12].

2.2. Complexity. Suppose the linear algebraic group $H$ acts morphically on the (irreducible) algebraic variety $X$. Let $B$ be a Borel subgroup of $H$. Recall that the complexity of $X$ (with respect to the $H$-action on $X$) is defined as

$$\kappa_H(X) := \min_{x \in X} \text{codim}_X B \cdot x,$$

see also [6], [25], [28], [32], and [49].

Since the Borel subgroups of $H$ are conjugate in $H$ ([20, Thm. 21.3]), the complexity of the variety $X$ is well-defined.

Since a Borel subgroup of $H$ is connected, we have $\kappa_H(X) = \kappa_{H^x}(X)$. Thus for considering the complexity of an $H$-action, we may assume that $H$ is connected.

Concerning basic properties of complexity, we refer the reader to [49, §9].

We return to the general situation of a linear algebraic group $H$ acting on an algebraic variety $X$. For a Borel subgroup $B$ of $H$, we define

$$\Gamma_X(B) := \{ x \in X \mid \text{codim}_X B \cdot x = \kappa_H(X) \} \subseteq X.$$

Then we set

$$\Gamma_X := \bigcup_{B \in \mathcal{B}} \Gamma_X(B) \subseteq X.$$

For $x \in X$, we define

$$\Lambda_H(x) := \{ B \in \mathcal{B} \mid \text{codim}_X B \cdot x = \kappa_H(X) \} \subseteq \mathcal{B}.$$

Remark 2.1. The following statements are immediate from the definitions.

(i) If $H$ acts transitively on $X$, then $\Gamma_X = X$.
(ii) $B \in \Lambda_H(x)$ if and only if $x \in \Gamma_X(B)$.
(iii) $\Lambda_H(x) = \emptyset$ if and only if $x \notin \Gamma_X$.

The complexity of a reducible variety can easily be determined from the complexities of its irreducible components: Since a Borel subgroup $B$ of $G$ is connected, it stabilizes each irreducible component of $X$, cf. [20, Prop. 8.2(d)]. Let $x \in \Gamma_X(B)$ and choose an irreducible component $X'$ of $X$ such that $x \in X'$. Then $\kappa_G(X) = \kappa_G(X') + \text{codim}_X X'$. Therefore, from now on we may assume that $X$ is irreducible.

Next we recall the upper semi-continuity of dimension, e.g. see [20, Prop. 4.4].
Proposition 2.2. Let $\varphi : X \to Y$ be a dominant morphism of irreducible varieties. For $x \in X$, let $\varepsilon_\varphi(x)$ be the maximal dimension of any component of $\varphi^{-1}(\varphi(x))$ passing through $x$. Then $\{x \in X \mid \varepsilon_\varphi(x) \geq n\}$ is closed in $X$, for all $n \in \mathbb{Z}$.

Corollary 2.3. Let $X$ be an $H$-variety. The set $\{x \in X \mid \dim H \cdot x \leq n\}$ is closed in $X$ for all $n \in \mathbb{Z}$. In particular, the union of all $H$-orbits of maximal dimension in $X$ is an open subset of $X$.

Lemma 2.4. For every $B \in \mathcal{B}$, we have $\Gamma_X(B)$ is a non-empty open subset of $X$.

Proof. Note that $\Gamma_X(B)$ is the union of $B$-orbits of maximal dimension. Thus, by Corollary 2.3, $\Gamma_X(B)$ is open in $X$. □

Corollary 2.5. $\Gamma_X$ is open in $X$.

Next we need an easy but useful lemma; the proof is elementary.

Lemma 2.6. Let $\varphi : X \to Y$ be an $H$-equivariant dominant morphism of irreducible $H$-varieties. For $x \in X$ set $F_{\varphi(x)} = \varphi^{-1}(\varphi(x))$. Then $F_{\varphi(x)}$ is $C_H(\varphi(x))$-stable.

Before we can prove the main result of this subsection we need another preliminary result, see [20, Thm. 4.3].

Theorem 2.7. Let $\varphi : X \to Y$ be a dominant morphism of irreducible varieties. Set $r = \dim X - \dim Y$. Then there is a non-empty open subset $V$ of $Y$ such that $V \subseteq \varphi(X)$ and if $Y' \subseteq Y$ is closed, irreducible and meets $V$ and $Z$ is a component of $\varphi^{-1}(Y')$ which meets $\varphi^{-1}(V)$, then $\dim Z = \dim Y' + r$. In particular, if $v \in V$, then $\dim \varphi^{-1}(v) = r$.

For the remainder of this section let $G$ be connected reductive. Let $\varphi : X \to Y$ be a $G$-equivariant dominant morphism of irreducible $G$-varieties. Then $\kappa_G(Y) \leq \kappa_G(X)$, [49, §9]. In the main result of this subsection we give an interpretation for the difference $\kappa_G(X) - \kappa_G(Y)$ in terms of the complexity of a smaller subgroup acting on a fibre of $\varphi$.

Theorem 2.8. Let $\varphi : X \to Y$ be a $G$-equivariant dominant morphism of irreducible $G$-varieties. For $x \in X$ set $F_{\varphi(x)} = \varphi^{-1}(\varphi(x))$. Then for every $B \in \mathcal{B}$ there exists $x \in \Gamma_X(B)$ such that for $H = C_B(\varphi(x))$ we have

$$\kappa_G(X) = \kappa_G(Y) + \kappa_H(Z),$$

where $Z$ is an irreducible component of $F_{\varphi(x)}$ passing through $x$.

Proof. Let $B \in \mathcal{B}$. Let $V$ be a non-empty open subset of $Y$ which satisfies the conditions in Theorem 2.7. Since $Y$ is irreducible, Lemma 2.4 implies that $\Gamma_Y(B) \cap V \neq \emptyset$. For $y \in \Gamma_Y(B) \cap V$, Theorem 2.7 implies that any component of $\varphi^{-1}(y)$ has dimension $r = \dim X - \dim Y$, in particular, $\dim \varphi^{-1}(y) = r$. Since $\varphi^{-1}(\Gamma_Y(B) \cap V)$ is open in $X$, we have $\varphi^{-1}(\Gamma_Y(B) \cap V) \cap \Gamma_X(B) \neq \emptyset$, by Lemma 2.4. Now choose $x \in \varphi^{-1}(\Gamma_Y(B) \cap V) \cap \Gamma_X(B)$. In particular, $\dim F_{\varphi(x)} = r$. Lemma 2.6 implies that $F_{\varphi(x)}$ is $C_B(\varphi(x))$-stable. Clearly, $C_B(x)$ is the stabilizer of $x$ in $C_B(\varphi(x))$. Thus we obtain
where the last equality holds because \( x \in \Gamma_X(B) \) and \( \varphi(x) \in \Gamma_Y(B) \).

Let \( Z \) be an irreducible component of \( F_{\varphi(x)} \) which passes through \( x \). Theorem 2.7 implies that \( Z \) has the same dimension as \( F_{\varphi(x)} \). The connected group \( H = C_B(\varphi(x))^0 \) stabilizes \( Z \). Note that for each \( z \in Z \) we have \( \varphi(z) = \varphi(x) \) and \( C_B(z) = C_{C_B(\varphi(x))}(z) \) (observed for \( z = x \) above). Since \( x \in \Gamma_X(B) \), \( \dim C_B(x) \) is minimal among groups of the form \( C_B(z) \) for \( z \in Z \). Therefore, because \( C_B(z) = C_{C_B(\varphi(x))}(z) \), we see that \( \dim C_{C_B(\varphi(x))}(x) \) is minimal among groups of the form \( C_{C_B(\varphi(x))}(z) \) for \( z \in Z \). We deduce that \( x \in \Gamma_Z(H) \). Consequently,

\[
\kappa_H(Z) = \dim Z - \dim C_B(\varphi(x))^0 + \dim C_{C_B(\varphi(x))}(x) = \dim_{F_{\varphi(x)}} C_B(\varphi(x)) \cdot x.
\]

The result follows. \( \Box \)

2.3. Spherical Varieties. A \( G \)-variety \( X \) is called spherical if a Borel subgroup of \( G \) acts on \( X \) with a dense orbit, that is \( \kappa_G(X) = 0 \). We recall some standard facts concerning spherical varieties, see [6], [25] and [32].

First we recall an important result due to É.B. Vinberg [49] and M. Brion [4] independently in characteristic zero and F. Knop [25, Cor. 2.6] in arbitrary characteristic. Let \( B \) be a Borel subgroup of \( G \).

**Theorem 2.9.** A spherical \( G \)-variety consists only of a finite number of \( B \)-orbits.

We have an immediate corollary.

**Corollary 2.10.** The following are equivalent.

(i) The \( G \)-variety \( X \) is spherical.

(ii) There is an open \( B \)-orbit in \( X \).

(iii) The number of \( B \)-orbits in \( X \) is finite.

2.4. Homogeneous Spaces. Let \( H \) be a closed subgroup of \( G \). Since \( G/H \) is a \( G \)-variety, we may consider the complexity \( \kappa_G(G/H) \). Let \( B \) be a Borel subgroup of \( G \). The orbits of \( B \) on \( G/H \) are in bijection with the \((B,H)\)-double cosets of \( G \). We have that \( \kappa_G(G/H) = \dim_{G/H} BgH/H \) for \( gH \in \Gamma_{G/H}(B) \). Clearly, \( G \) acts transitively on \( G/H \), so Remark 2.1(i) implies that we can choose a Borel subgroup \( B \) such that \( B \in \Lambda_G(1H) \). Thus, for this choice of \( B \), we have

\[
\kappa_G(G/H) = \dim_{G/H} B g H / H = \dim G / H - \dim B H / H
\]

(2.11)

\[
= \dim G / H - \dim B / B \cap H
\]

\[
= \dim G - \dim H - \dim B + \dim B \cap H.
\]

Following M. Krämer [26], a subgroup \( H \) of \( G \) is called spherical if \( \kappa_G(G/H) = 0 \).
Lemma 2.12. Let $G$ be a connected reductive and let $H$ be a subgroup of $G$ which contains the unipotent radical of a Borel subgroup of $G$. Then $H$ is spherical. In particular, a parabolic subgroup of $G$ is spherical.

Proof. Let $B$ be a Borel subgroup of $G$ such that $U = R_u(B) \subseteq H$. Denote by $B^-$ the opposite Borel subgroup to $B$, relative to some maximal torus of $B$, see [20, §26.2 Cor. C]. The big cell $B^- U$ is an open subset of $G$, [20, Prop. 28.5]. We have $B^- U \subseteq B^- H$, so $B^- H$ is a dense subset of $G$. Thus, $G/H$ is spherical. 

Remark 2.13. If both $G$ and $H$ are reductive, then $G/H$ is an affine variety, see [39, Thm. A]. This case has been studied greatly. The classification of spherical reductive subgroups of the simple algebraic groups in characteristic zero was obtained by M. Krämer [26] and was shown to be the same in positive characteristic by J. Brundan [7]. M. Brion [5] classifies all the spherical reductive subgroups of an arbitrary reductive group in characteristic zero. In positive characteristic no such classification is known. However, the classification of the reductive spherical subgroups in simple algebraic groups in positive characteristic follows from work of T.A. Springer [46] (see also G. Seitz [44]), J. Brundan [7] and R. Lawther [27].

Important examples of reductive spherical subgroups are centralizers of involutive automorphisms of $G$: Suppose that $\text{char } k \neq 2$ and let $\theta$ be an involutive automorphism of $G$. Then the fixed point subgroup $C_G(\theta) = \{ g \in G \mid \theta(g) = g \}$ of $G$ is spherical, see [46, Cor. 4.3.1].

For more on the complexity and sphericity of homogeneous spaces see [4, 28] and [31].

Remark 2.14. In order to compute the complexity of an orbit variety, it suffices to determine the complexity of a homogeneous space. For, suppose that $G$ acts on an algebraic variety $X$. Let $x \in X$. Since $G$ is connected, the orbit $G \cdot x$ is irreducible. The map $\pi_x : G/C_G(x) \rightarrow G \cdot x$, by $\pi_x(gC_G(x)) = g \cdot x$ is a bijective $G$-equivariant morphism, [22, §2.1]. Thus, by applying Theorem 2.8 to $\pi_x$, we have

\begin{equation}
(2.15) \quad \kappa_G(G/C_G(x)) = \kappa_G(G \cdot x).
\end{equation}

The relevance of (2.15) is that the left hand side is easier to compute, since calculating $\kappa_G(G/C_G(x))$ only requires the study of groups of the form $C_B(x)$, cf. (2.11), where $B$ is a Borel subgroup of $G$.

2.5. Kempf–Rousseau Theory. Next we require some standard facts from Geometric Invariant Theory, see [24], also see [37, §2], [40, §7]. Let $X$ be an affine variety and $\phi : k^* \rightarrow X$ be a morphism of algebraic varieties. We say that $\lim_{t \to 0} \phi(t)$ exists if there exists a morphism $\hat{\phi} : k \rightarrow X$ such that $\hat{\phi}|_{k^*} = \phi$. If such a limit exists, we set $\lim_{t \to 0} \phi(t) = \hat{\phi}(0)$. Note, that if such a morphism $\hat{\phi}$ exists, it is necessarily unique.

Let $\lambda$ be a cocharacter of $G$. Define $P_\lambda = \{ x \in G \mid \lim_{t \to 0} \lambda(t)x\lambda(t)^{-1} \text{ exists} \}$. Then $P_\lambda$ is a parabolic subgroup of $G$, the unipotent radical of $P_\lambda$ is given by $R_u(P_\lambda) = \{ x \in G \mid \lim_{t \to 0} \lambda(t)x\lambda(t)^{-1} = 1 \}$, and a Levi subgroup of $P_\lambda$ is the centralizer $G_G(\lambda) = C_G(\lambda(k^*))$ of the image of $\lambda$ in $G$, [47, §8.4].
Let the connected reductive group $G$ act on the affine variety $X$ and suppose $x \in X$ is a point such that $G \cdot x$ is not closed in $X$. Let $C$ denote the unique closed $G$-orbit in the closure of $G \cdot x$, cf. [39, Lem. 1.4]. Set $\Lambda(x) := \{ \lambda \in Y(G) \mid \lim_{t \to 0} \lambda(t) \cdot x \text{ exists and lies in } C \}$. Then there is a so-called optimal class $\Omega(x) \subseteq \Lambda(x)$ of cocharacters associated to $x$. The following theorem is due to G.R. Kempf, [24, Thm. 3.4] (see also [43]).

**Theorem 2.16.** Assume as above. Then we have the following:

1. $\Omega(x) \neq \emptyset$.
2. There exists a parabolic subgroup $P(x)$ of $G$ such that $P(x) = P_\lambda$ for every $\lambda \in \Omega(x)$.
3. $\Omega(x)$ is a single $P(x)$-orbit.
4. For $g \in G$, we have $\Omega(g \cdot x) = g \cdot \Omega(x)$ and $P(g \cdot x) = gP(x)g^{-1}$. In particular, $C_G(x) \leq N_G(P(x)) = P(x)$.

Frequently, $P(x)$ in Theorem 2.16 is called the destabilizing parabolic subgroup of $G$ defined by $x \in X$.

2.6. **Associated Cocharacters.** In this subsection we closely follow A. Premet [37]; also see [22, §5]. We recall that $p$ is a good prime for $G$ throughout this section.

Every cocharacter $\lambda \in Y(G)$ induces a grading of $\mathfrak{g}$:

$$\mathfrak{g} = \bigoplus_{i \in \mathbb{Z}} \mathfrak{g}(i, \lambda),$$

where

$$\mathfrak{g}(i, \lambda) = \{ x \in \mathfrak{g} \mid \text{Ad}(\lambda(t))(x) = t^i x \text{ for all } t \in k^* \},$$

see [22, §5.1]. For $P_\lambda$ as in the the previous subsection, we have the following equalities:

$$\text{Lie } P_\lambda = \bigoplus_{i \geq 0} \mathfrak{g}(i, \lambda); \text{ Lie } R_u(P_\lambda) = \bigoplus_{i > 0} \mathfrak{g}(i, \lambda); \text{ and Lie } C_G(\lambda) = \mathfrak{g}(0, \lambda).$$

Frequently, we write $\mathfrak{g}(i)$ for $\mathfrak{g}(i, \lambda)$ once we have fixed a cocharacter $\lambda \in Y(G)$.

Let $H$ be a connected reductive subgroup of $G$. A nilpotent element $e \in \mathfrak{h}$ is called distinguished in $\mathfrak{h}$ provided each torus in $C_H(e)$ is contained in the centre of $H$, [22, §4.1].

The following characterization of distinguished nilpotent elements in the Lie algebra of a Levi subgroup of $G$ can be found in [22, §4.6, §4.7].

**Proposition 2.17.** Let $e \in \mathfrak{g}$ be nilpotent and let $L$ be a Levi subgroup of $G$. Then $e$ is distinguished in $\text{Lie } L$ if and only if $L = C_G(S)$, where $S$ is a maximal torus of $C_G(e)$.

Next we recall the definition of an associated cocharacter, see [22, §5.3].

**Definition 2.18.** A cocharacter $\lambda : k^* \to G$ is associated to $e \in \mathcal{N}$ if $e \in \mathfrak{g}(2, \lambda)$ and there exists a Levi subgroup $L$ of $G$ such that $e$ is distinguished in Lie $L$, and $\lambda(k^*) \leq DL$.

**Remark 2.19.** In view of Proposition 2.17, the last two conditions in Definition 2.18 are equivalent to the existence of a maximal torus $S$ of $C_G(e)$ such that $\lambda(k^*) \leq DC_G(S)$. We will use this fact frequently in the sequel.

Let $e \in \mathcal{N}$. In [37, §2.4, Prop. 2.5], A. Premet explicitly defines a cocharacter of $G$ which is associated to $e$. Moreover, in [37, Thm. 2.3], Premet shows that each of these associated cocharacters belongs to the optimal class $\Omega(e)$ determined by $e$. Premet shows this under the so called standard hypotheses on $G$, see [22, §2.9]. These restrictions were subsequently removed by G. McNinch in [29, Prop. 16] so that this fact holds for any connected reductive
group $G$ in good characteristic. It thus follows from [29, Prop. 16], Theorem 2.16(iv), and the fact that any two associated cocharacters are conjugate under $C_G(e)$, [22, Lem. 5.3], that all the cocharacters of $G$ associated to $e \in \mathcal{N}$ belong to the optimal class $\Omega(e)$ defined by $e$; see also [29, Prop. 18, Thm. 21]. This motivates and justifies the following notation which we use in the sequel.

**Definition 2.20.** Let $e \in \mathfrak{g}$ be nilpotent. Then we denote the set of cocharacters of $G$ associated to $e$ by

$$\Omega^a_G(e) := \{ \lambda \in Y(G) \mid \lambda \text{ is associated to } e \} \subseteq \Omega(e).$$

Further, if $H$ is a (connected) reductive subgroup of $G$ with $e \in \mathfrak{h}$ nilpotent we also write $\Omega^a_H(e)$ to denote the cocharacters of $H$ that are associated to $e$.

As indicated above, in good characteristic, associated cocharacters are known to exist for any nilpotent element $e \in \mathfrak{g}$; more precisely, we have the following, [22, §5.3]:

**Proposition 2.21.** Suppose that $p$ is good for $G$. Let $e \in \mathfrak{g}$ be nilpotent. Then $\Omega^a_G(e) \neq \emptyset$. Moreover, if $\lambda \in \Omega^a_G(e)$ and $\mu \in Y(G)$, then $\mu \in \Omega^a_G(e)$ if and only if $\mu$ and $\lambda$ are conjugate by an element of $C_G(e)$.

Fix a nilpotent element $e \in \mathfrak{g}$ and an associated cocharacter $\lambda \in \Omega^a_G(e)$ of $G$. Set $P = P_\lambda$. By Theorem 2.16(ii), $P$ only depends on $e$ and not on the choice of the associated cocharacter $\lambda$. Note that $C_G(\lambda)$ stabilizes $\mathfrak{g}(i)$ for every $i \in \mathbb{Z}$. For $n \in \mathbb{Z}_{\geq 0}$ we set

$$\mathfrak{g}_{\geq n} = \bigoplus_{i \geq n} \mathfrak{g}(i) \quad \text{and} \quad \mathfrak{g}_{>n} = \bigoplus_{i > n} \mathfrak{g}(i).$$

Then we have

$$\mathfrak{g}_{\geq 0} = \text{Lie } P \quad \text{and} \quad \mathfrak{g}_{>0} = \text{Lie } R_u(P).$$

Also, $C_G(e) = C_P(e)$, by Theorem 2.16(iv).

The next result is [22, Prop. 5.9(c)].

**Proposition 2.22.** The $P$-orbit of $e$ in $\mathfrak{g}_{\geq 2}$ is dense in $\mathfrak{g}_{\geq 2}$.

**Corollary 2.23.** The $C_G(\lambda)$-orbit of $e$ in $\mathfrak{g}(2)$ is dense in $\mathfrak{g}(2)$.

Define

$$C_G(e, \lambda) := C_G(e) \cap C_G(\lambda).$$

**Corollary 2.24.** Let $e \in \mathcal{N}$. Then

(i) $\dim C_G(e) = \dim \mathfrak{g}(0) + \dim \mathfrak{g}(1)$;
(ii) $\dim R_u(C_G(e)) = \dim \mathfrak{g}(1) + \dim \mathfrak{g}(2)$;
(iii) $\dim C_G(e, \lambda) = \dim \mathfrak{g}(0) - \dim \mathfrak{g}(2)$.

**Proof.** As $C_G(e) = C_P(e)$, part (i) is immediate from Proposition 2.22. Using the fact that $(\text{Ad}(R_u(P)) - 1)(e) \subseteq \mathfrak{g}_{\geq 3}$ (e.g. see [22, §5.10]) and Proposition 2.22, we see that $\dim \text{Ad}(R_u(P))(e) = \dim \mathfrak{g}_{\geq 3}$ and so $\dim C_{R_u(P)}(e) = \dim \mathfrak{g}(1) + \dim \mathfrak{g}(2)$. Finally, part (iii) follows from the first two. □

The following basic result regarding the structure of $C_G(e)$ can be found in [37, Thm. A].
Proposition 2.25. If char $k$ is good for $G$, then $C_G(e)$ is the semi-direct product of $C_G(e, \lambda)$ and $C_G(e) \cap R_u(P)$. Moreover, $C_G(e, \lambda)''$ is reductive and $C_G(e) \cap R_u(P)$ is the unipotent radical of $C_G(e)$.

Definition 2.26. Let $e \in \mathfrak{g}$ be nilpotent. The height of $e$ with respect to an associated cocharacter $\lambda \in \Omega^\alpha_G(e)$ is defined to be

$$ht(e) := \max_{i \in \mathbb{N}} \{ i \mid g(i, \lambda) \neq 0 \}.$$

Thanks to Proposition 2.21, the height of $e$ does not depend on the choice of $\lambda \in \Omega^\alpha_G(e)$. Since conjugate nilpotent elements have the same height, we may speak of the height of a given nilpotent orbit. Since $\lambda \in \Omega^\alpha_G(e)$, we have $ht(e) \geq 2$ for any nilpotent element $e \in \mathfrak{g}$, cf. Definition 2.18.

Let $\mathfrak{g}$ be classical with natural module $V$. Set $n = \dim V$. We write a partition $\pi$ of $n$ in one of the following two ways, either $\pi = (d_1, d_2, \ldots, d_r)$ with $d_1 \geq d_2 \geq \cdots \geq d_r \geq 0$ and $\sum_{i=1}^r d_i = n$, or $\pi = [1^{r_1}, 2^{r_2}, \ldots]$ with $\sum_i ir_i = n$. These two notations are related by $r_i = |\{ j \mid d_j = i \}|$ for $i \geq 1$.

For $\mathfrak{g}$ classical with natural module $V$ it is straightforward to determine the height of a nilpotent orbit from the corresponding partition of $\dim V$. We leave the proof of the next proposition to the reader.

Proposition 2.27. Let $e \in \mathfrak{g}$ be nilpotent with partition $\pi_e = (d_1, d_2, \ldots, d_r)$.

(i) If $\mathfrak{g} = \mathfrak{gl}(V), \mathfrak{sl}(V)$ or $\mathfrak{sp}(V)$, then $ht(e) = 2(d_1 - 1)$.

(ii) If $\mathfrak{g} = \mathfrak{so}(V)$, then $ht(e) = \begin{cases} 2(d_1 - 1) & \text{if } d_1 = d_2, \\ 2d_1 - 3 & \text{if } d_1 = d_2 + 1, \\ 2(d_1 - 2) & \text{if } d_1 > d_2 + 1. \end{cases}$

Remarks 2.28. (i). For char $k = 0$, Proposition 2.27 was proved in [33, Thm. 2.3].

(ii). If $e$ is a nilpotent element in $\mathfrak{gl}(V), \mathfrak{sl}(V)$ or $\mathfrak{sp}(V)$, then $ht(e)$ is even. If $e$ is a nilpotent element in $\mathfrak{so}(V)$, then $ht(e)$ is odd if and only if $d_2 = d_1 - 1$.

2.7. Fibre Bundles. Let $H$ be a closed subgroup of $G$. Suppose that $H$ acts on an affine variety $Y$. Define a morphic action of $H$ on the affine variety $G \times Y$ by $h \cdot (g, y) = (gh, h^{-1} \cdot y)$ for $h \in H, g \in G$ and $y \in Y$. Since $H$ acts fixed point freely on $G \times Y$, every $H$-orbit in $G \times Y$ has dimension $\dim H$. There exists a surjective quotient morphism $\rho : G \times Y \to (G \times Y)/H$, [30, §1.2], [36, §4.8]. We denote the quotient $(G \times Y)/H$ by $G \ast_H Y$, the fibre bundle associated to the principal bundle $\pi : G \to G/H$ defined by $\pi(g) = gH$ and fibre $Y$. We denote the element $(g, y)H$ of $G \ast_H Y$ simply by $g \ast y$, see [38, §2]. Let $X$ be a $G$-variety and $Y \subseteq X$ be an $H$-subvariety. The collapsing of the fibre bundle $G \ast_H Y$ is the morphism $G \ast_H Y \to G \cdot Y \subseteq X$ defined by $g \ast y \to g \cdot y$.

Define an action of $G$ on $G \ast_H Y$ by $g \cdot (g' \ast y) = (gg') \ast y$ for $g, g' \in G$ and $y \in Y$. We then have a $G$-equivariant surjective morphism $\varphi : G \ast_H Y \to G/H$ by $\varphi(g \ast y) = gH$. Note that $\varphi^{-1}(gH) \cong Y$ for all $gH \in G/H$.

Proposition 2.29. Let $H$ be a closed subgroup of $G$ and let $Y$ be an $H$-variety. Suppose that $B$ is a Borel subgroup of $G$ such that $\dim B \cap H$ is minimal (among all subgroups of the form $B' \cap H$ for $B'$ ranging over $B$). Then we have

$$\kappa_G(G \ast_H Y) = \kappa_G(G/H) + \kappa_{B \cap H}(Y).$$
Proof. We apply Theorem 2.8 to the morphism \( \varphi : G_\ast Y \to G/H \). Thus, for a Borel subgroup \( B \) of \( G \) and \( g \ast y \in \Gamma_{g \ast Y}(B) \), we have that \( \kappa_G(G_\ast Y) = \kappa_G(G/H) + \kappa_K(Z) \), where \( Z \) is an irreducible component of \( \varphi^{-1}(g \ast y) \) passing through \( g \ast y \), \( K = C_B(gH) \). Note that \( C_B(gH) = B \cap gHg^{-1} \). So, since \( g \ast y \in \Gamma_{g \ast Y}(B) \), the dimension of \( g^{-1}C_B(gH)g = g^{-1}Bg \cap H \) is minimal. Now, as \( G_\ast Y \) is a fibre bundle, for \( x \in G \) we have \( Y_x := \varphi^{-1}(\varphi(x \ast y)) \cong Y \).

Define a morphism \( \phi : Y_x \to Y \) by \( \phi(g \ast y) = x^{-1}g \cdot y \). Clearly, \( xhx^{-1} \ast g \ast y \in B \cap xhx^{-1} \) acts on \( g \ast y \in Y_x \), as \( xhx^{-1} \cdot (g \ast y) = xhx^{-1}g \ast y \). Since \( g = xh' \) for some \( h' \in H \), we have \( xhx^{-1} \cdot (g \ast y) = xhx^{-1}h' \cdot y \). So \( \phi(xh'h' \ast y) = hh' \cdot y \). Thus, if we define an action of \( B \cap xhx^{-1} \) on \( Y \) by \( xhx^{-1} \cdot y = h \cdot y \), the morphism \( \phi : Y_x \to Y \) becomes a \( (B \cap xhx^{-1}) \)-equivariant isomorphism. It follows that \( \kappa_{B \cap xhx^{-1}}(Y_x) = \kappa_{B \cap xhx^{-1}}(Y) \). Since \( x^{-1}(B \cap xhx^{-1})x = x^{-1}Bx \cap H \), we finally get \( \kappa_{B \cap xhx^{-1}}(Y) = \kappa_{x^{-1}Bx \cap H}(Y) \). The result follows. \( \square \)

Next we need a technical lemma.

Lemma 2.30. Let \( P \) be a parabolic subgroup of \( G \). Then for \( B \) ranging over \( B \), the intersection \( B \cap P \) is minimal if and only if \( B \cap P \) is a Borel subgroup of a Levi subgroup of \( P \).

Proof. We may choose a Borel subgroup \( B \) of \( G \) so that \( BP \) is open dense in \( G \), cf. the proof of Lemma 2.12. Then the \( P \)-orbit of the base point in \( G/B \cong B \) is open dense in \( B \). Consequently, the stabilizer of this base point in \( P \), that is \( P \cap B \) is minimal among all the isotropy subgroups \( P \cap B' \) for \( B' \) in \( B \). Clearly, \( P \) is opposite to a Borel subgroup of \( G \) contained in \( P \). Thanks to [2, Cor. 14.13], \( P \cap B \) contains a maximal torus \( T \) of \( G \).

Let \( L \) be the unique Levi subgroup of \( P \) containing \( T \). Then [10, Thm. 2.8.7] implies that \( P \cap B = T(R_u(B) \cap L) \). Clearly, \( T(R_u(B) \cap L) \) is solvable and thus lies in a Borel subgroup of \( L \). A simple dimension counting argument, using Theorem 2.7 applied to the multiplication map \( B \times P \to BP \) and the fact that \( \dim BP = \dim G \), shows that \( P \cap B \) is a Borel subgroup of \( L \).

Reversing the argument in the previous paragraph shows that if \( P \cap B \) is a Borel subgroup of \( L \), then \( BP \) is dense in \( G \) and thus \( P \cap B \) is minimal again in the sense of the statement. \( \square \)

Next we consider a special case of Proposition 2.29.

Lemma 2.31. Let \( P \) be a parabolic subgroup of \( G \) and let \( Y \) be a \( P \)-variety. Then

\[
\kappa_G(G_\ast PY) = \kappa_L(Y),
\]

where \( L \) is a Levi subgroup of \( P \).

Proof. Proposition 2.29 implies that \( \kappa_G(G_\ast PY) = \kappa_G(G/P) + \kappa_{B \cap P}(Y) \), where \( \dim B \cap P \) is minimal. Lemmas 2.12 and 2.30 imply that \( \kappa_G(G/P) = 0 \) and \( B \cap P \) is a Borel subgroup of a Levi subgroup of \( P \). The result follows. \( \square \)

Let \( e \in \mathcal{N} \) be a non-zero nilpotent element, \( \lambda \in \Omega_{G_e}(e) \) be an associated cocharacter of \( e \) and \( \mathfrak{g} = \bigoplus_{i \in \mathbb{Z}} \mathfrak{g}(i) \) be the grading of \( \mathfrak{g} \) induced by \( \lambda \). Also let \( P \) be the destabilizing parabolic subgroup of \( G \) defined by \( e \), cf. Subsection 2.5. In particular, we have \( \text{Lie} P = \mathfrak{g}_{\geq 2} \), see Subsection 2.6.

Lemma 2.32. Let \( e \in \mathcal{N} \). Then \( G \cdot \mathfrak{g}_{\geq 2} = \overline{G \cdot e} \). In particular, \( \dim G \cdot \mathfrak{g}_{\geq 2} = \dim G \cdot e \).
Proof. Since \( g \geq 2 \) is \( P \)-stable, \( G \cdot g \geq 2 \) is closed, [21, Prop. 0.15]. Thus, since \( e \in g(2) \subseteq g \geq 2 \), we have \( G \cdot e \subseteq G \cdot g \geq 2 \). By Proposition 2.22, \( P \cdot e = g \geq 2 \). Since \( P \cdot e \subseteq G \cdot e \), we thus have \( g \geq 2 \subseteq G \cdot e \). Finally, as \( G \cdot e \) is \( G \)-stable, \( G \cdot g \geq 2 \subseteq G \cdot e \). The result follows. \( \square \)

Theorem 2.33. Let \( e \in \mathcal{N} \). Then

\[
\kappa_G(G \cdot e) = \kappa_L(g \geq 2),
\]

where \( L \) is a Levi subgroup of \( P \).

Proof. We have \( \kappa_G(G \cdot e) = \kappa_G(G/C(e)) = \kappa_G(G/C_P(e)) \), thanks to (2.15) and the fact that \( G_G(e) = C_P(e) \). Moreover, since \( G \cdot P P /C_P(e) \cong G/C_P(e) \), it follows from Lemma 2.31 that \( \kappa_G(G/C_P(e)) = \kappa_L(P/C_P(e)) \). Finally, thanks to Proposition 2.22 and (2.15), we obtain \( \kappa_L(P/C_P(e)) = \kappa_L(g \geq 2) \). The result follows. \( \square \)

Remark 2.34. For \( \text{char} \ k = 0 \), Theorem 2.33 was proved by Panyushev in [33, Thm. 4.2.2].

Remark 2.35. Thanks to Theorem 2.33, in order to determine whether a nilpotent orbit is spherical, it suffices to show that a Borel subgroup of a Levi subgroup of \( P \) acts on \( g \geq 2 \) with a dense orbit. In our classification we pursue this approach.

2.8. Borel Subgroups of Levi Subgroups Acting on Unipotent Radicals. Let \( e \in g \) be a non-zero nilpotent element and \( \lambda \in \Omega_G^s(e) \) be an associated cocharacter for \( e \). Let \( P = P_\lambda \) be the destabilizing parabolic subgroup defined by \( e \). We denote the Levi subgroup \( C_G(\lambda) \) of \( P \) by \( L \). Our next result is taken from [22, §3]. We only consider the case when \( G \) is simple, the extension to the case when \( G \) is reductive is straightforward.

Proposition 2.36. Let \( G \) be a simple classical algebraic group and \( 0 \neq e \in g \) be nilpotent with corresponding partition \( \pi_e = [1^s_1, 2^s_2, 3^s_3, \ldots] \). Let \( a_i, b_i, s, t \in \mathbb{Z}_{\geq 0} \) such that \( a_i + 1 = \sum_{j \geq 1} r_{2j+1}, b_i + 1 = \sum_{j \geq 1} r_{2j}, 2s = \sum_{j \geq 0} r_{2j+1}, \text{ and } 2t = \sum_{j \geq 0} r_{2j+1} \). Then the structure of \( DL \) is as follows.

(i) If \( G \) is of type \( A_n \), then \( DL \) is of type \( \prod_{i \geq 0} A_{a_i} \times \prod_{i \geq 1} A_{b_i} \).
(ii) If \( G \) is of type \( B_n \), then \( DL \) is of type \( \prod_{i \geq 1} A_{a_i} \times \prod_{i \geq 1} A_{b_i} \times B_t \).
(iii) If \( G \) is of type \( C_n \), then \( DL \) is of type \( \prod_{i \geq 1} A_{a_i} \times \prod_{i \geq 1} A_{b_i} \times C_s \).
(iv) If \( G \) is of type \( D_n \), then \( DL \) is of type \( \prod_{i \geq 1} A_{a_i} \times \prod_{i \geq 1} A_{b_i} \times D_s \).

We use the conventions that \( A_0 = B_0 = C_0 = D_0 = \{1\}, D_1 \cong k^* \) and \( D_2 = A_1 \times A_1 \).

In order to describe the Levi subgroups \( C_G(\lambda) \) for the exceptional groups we need to know more about associated cocharacters. Let \( T \) be a maximal torus of \( G \) such that \( \lambda(k^*) \leq T \). Now let \( G_C \) be the simple, simply connected group over \( C \) with the same root system as \( G \). Let \( g_C \) be the Lie algebra of \( G_C \). For a nilpotent element \( e \in g_C \) we can find an \( sl_2 \)-triple containing \( e \). Let \( h \in g_C \) be the semisimple element of this \( sl_2 \)-triple. Note that \( h \) is the image of 1 under the differential of \( \lambda_C \in G_C \) (corresponding to \( \lambda \)) at 1. Then there exists \( \alpha(h) \geq 0 \) for all \( \alpha \in \Psi^+ \) and \( \alpha(h) = m_\alpha \in \{0, 1, 2\} \) for all \( \alpha \in \Pi \), see [10, §6.6]. For each simple root \( \alpha \in \Pi \) we attach the numerical label \( m_\alpha \) to the corresponding node of the Dynkin diagram. The resulting labels form the weighted Dynkin diagram \( \Delta(e) \) of \( e \). We denote the set of weighted Dynkin diagrams of \( G \) by \( D(\Pi) \). For \( e, e' \in g_C \) nilpotent, we have that \( \Delta(e) = \Delta(e') \) if and only if \( e \) and \( e' \) are in the same \( G_C \)-orbit.
In order to determine the weighted Dynkin diagram of a given nilpotent orbit we refer to the method outlined in [10, §13] for the classical groups, and to the tables in loc. cit. for the exceptional groups.

We return to the case when the characteristic of $k$ is good for $G$. In this case the classification of the nilpotent orbits does not depend on the field $k$. [10, §5.11]. Recently, in [37] Premet gave a proof of this fact for the unipotent classes of $G$ which is free from case by case considerations. This applies in our case, since the classification of the unipotent conjugacy classes in $G$ and of the nilpotent orbits in $\mathcal{N}$ is the same in good characteristic, [10, §9 and §11]. First assume that $G$ is simply connected and that $G$ admits a finite-dimensional rational representation such that the trace form on $\mathfrak{g}$ is non-degenerate; see [37, §2.3] for the motivation of these assumptions. Under these assumptions, given $\Delta \in \mathcal{D}(\Pi)$, there exists a cocharacter $\lambda = \lambda_\Delta$ of $G$ which is associated to $e$, where $e$ lies in the dense $L$-orbit in $\mathfrak{g}(2, \lambda)$, for $L = C_G(\lambda)$, such that
\begin{equation}
Ad(\lambda(t))(e_{\pm\alpha}) = t^{\pm m_\alpha}e_{\pm\alpha} \quad \text{and} \quad Ad(\lambda(t))(x) = x
\end{equation}
for all $\alpha \in \Pi, e_{\pm\alpha} \in \mathfrak{g}_{\pm\alpha}, x \in t$ and $t \in k^*$, [37, §2.4]. We extend this action linearly to all of $\mathfrak{g}$. Now return to the general simple case. Let $\hat{G}$ be the simple, simply connected group with the same root datum as $G$. Then there exists a surjective central isogeny $\tau : \hat{G} \rightarrow G$, [10, §1.11]. Also, an associated cocharacter for $e = d\pi(\hat{e})$ in $\mathfrak{g}$ is of the form $\pi \circ \hat{\lambda}$, where $\lambda$ is a cocharacter of $\hat{G}$ that is associated to $\hat{e}$ in $\hat{\mathfrak{g}}$. This implies that (2.37) holds for an arbitrary simple algebraic group, when the characteristic of $k$ is good for $G$.

After these deliberations we can use the tables in [10, §13] to determine the structure of the Levi subgroup $C_G(\lambda)$ for the exceptional groups. Recall that $\text{Lie} C_G(\lambda) = \mathfrak{g}(0)$ and $\mathfrak{g}(0)$ is the sum of the root spaces $\mathfrak{g}_\alpha$, where $\alpha \in \Psi$ with $\langle \alpha, \lambda \rangle = 0$. Let $\Pi_0 = \{ \alpha \in \Pi \mid m_\alpha = 0 \}$, the set of nodes $\alpha$ of the corresponding weighted Dynkin diagram with label $m_\alpha = 0$. Then $C_G(\lambda) = \langle T, U_\pm \alpha \mid \alpha \in \Pi_0 \rangle$.

It is straightforward to determine the height of a nilpotent orbit from its associated weighted Dynkin diagram. Let $\hat{\alpha} = \sum_{\alpha \in \Pi} c_\alpha \alpha$ be the highest root of $\Psi$. For each simple root $\alpha \in \Pi$ we have $\mathfrak{g}_\alpha \subseteq \mathfrak{g}(m_\alpha)$ where $m_\alpha$ is the corresponding numerical label on the weighted Dynkin diagram, by (2.37).

**Lemma 2.38.** Let $\hat{\alpha}$ be the highest root of $\Psi$ and set $d = \text{ht}(e)$. Then $\mathfrak{g}_{\hat{\alpha}} \subseteq \mathfrak{g}(d)$.

**Proof.** Clearly, we have $\mathfrak{g}_{\hat{\alpha}} \subseteq \mathfrak{g}(i)$ for some $i \geq 0$. The lemma is immediate, because if $\hat{\alpha} = \sum_{\alpha \in \Pi} c_\alpha \alpha$ and $\beta = \sum_{\alpha \in \Pi} d_\alpha \alpha$ is any other root of $\Psi$, then $c_\alpha \geq d_\alpha$ for all $\alpha \in \Pi$. 

Lemma 2.38 readily implies
\begin{equation}
\text{ht}(e) = \sum_{\alpha \in \Pi} m_\alpha c_\alpha.
\end{equation}
The identity (2.39) is also observed in [32, §2.1].

For the remainder of this section we assume that $G$ is simple. The generalization of each of the subsequent results to the case when $G$ is reductive is straightforward.

For $P$ a parabolic subgroup of $G$ we set $\mathfrak{p}_u = \text{Lie} R_u(P)$.

**Proposition 2.40.** Let $P = LR_u(P)$ be an arbitrary parabolic subgroup of $G$, where $L$ is a Levi subgroup of $P$. Then
\[
\kappa_G(G/L) = \kappa_L(P/L) = \kappa_L(R_u(P)) = \kappa_L(\mathfrak{p}_u).
\]
Proof. Thanks to Lemma 2.31, we have $\kappa_L(G/L) = \kappa_G(G \ast_P P/L) = \kappa_L(P/L)$.

If we write $P = R_u(P)L$, then the bijection $P/L = R_u(P)L/L \cong R_u(P)$ gives a canonical $L$-equivariant isomorphism $\phi : P/L \to R_u(P)$ defined by $\phi(xL) = y$, where $x = yz$ with $y \in R_u(P)$ and $z \in L$. Thus, we have $\kappa_L(P/L) = \kappa_L(R_u(P))$.

A Springer isomorphism between the unipotent variety of $G$ and $N$ restricts to an $L$-equivariant isomorphism $R_u(P) \to p_u$, e.g., see [14, Cor. 1.4], so that $\kappa_L(R_u(P)) = \kappa_L(p_u)$. \qed

Remarks 2.41. (i). While the first two equalities of Proposition 2.40 hold in arbitrary characteristic, the third equality requires the characteristic of the underlying field to be zero or a good prime for $G$; this assumption is required for the existence of a Springer isomorphism, cf. [14, Cor. 1.4].

(ii). Lemma 4.2 in [7] states that there is a dense $L$-orbit on $G/B$ if and only if there is a dense $B_L$-orbit on $R_u(P)$, where $B_L$ is a Borel subgroup of $L$. Notice that there is a dense $L$-orbit on $G/B$ if and only if there is a dense $B$-orbit on $G/L$. In other words, $\kappa_G(G/L) = 0$ if and only if $\kappa_L(R_u(P)) = 0$. Thus, Proposition 2.40 generalizes [7, Lem. 4.2].

By Proposition 2.40, the problem of determining $\kappa_L(R_u(P))$ is equivalent to the problem of determining $\kappa_G(G/L)$. In particular, a Borel subgroup of $L$ acts on $R_u(P)$ with a dense orbit if and only if $L$ is a spherical subgroup of $G$. In fact, the latter have been classified: In characteristic zero this result was proved by M. Krämer in [26] and extended to arbitrary characteristic by J. Brundan in [7, Thm. 4.1]:

Theorem 2.42. Let $L$ be a proper Levi subgroup of a simple group $G$. Then $L$ is spherical in $G$ if and only if $(G, DL)$ is one of $(A_n, A_{n-1}A_{n-1})$, $(B_n, B_{n-1})$, $(B_n, A_{n-1})$, $(C_n, C_{n-1})$, $(C_n, A_{n-1})$, $(D_n, D_{n-1})$, $(D_n, A_{n-1})$, $(E_6, D_5)$, or $(E_7, E_6)$.

We also recall the classification of the parabolic subgroups of $G$ with an abelian unipotent radical, cf. [41, Lem. 2.2].

Lemma 2.43. Let $G$ be a simple algebraic group and $P$ be a parabolic subgroup of $G$. Then $R_u(P)$ is abelian if and only if $P$ is a maximal parabolic subgroup of $G$ which is conjugate to the standard parabolic subgroup $P_I$ of $G$, where $I = \Pi \setminus \{\alpha\}$ and $\alpha$ occurs in the highest root $\check{\alpha}$ with coefficient 1.

Let $\Pi = \{\alpha_1, \alpha_2, \ldots, \alpha_n\}$ be a set of simple roots of the root system $\Psi$ of $G$. Using Lemma 2.43, we can readily determine the standard parabolic subgroups $P_I$ of $G$ with an abelian unipotent radical. For $G$ simple we gather this information in Table 1 below along with the structure of the corresponding standard Levi subgroup $L_I$ of $P_I$. Set $P_{\alpha_i} = P_{I \setminus \{\alpha_i\}}$. Here the simple roots are labelled as in [3, Planches I - IX].

Note that if $G$ is of type $E_8$, $F_4$ or $G_2$, then $G$ does not admit a parabolic subgroup with an abelian unipotent radical. Also compare the list of pairs $(G, DL)$ from Table 1 with the list in Theorem 2.42.

Our next result is immediate from [7, Thm. 4.1, Lem. 4.2].

Proposition 2.44. If $P = LR_u(P)$ is a parabolic subgroup of $G$ with $R_u(P)$ abelian, then $\kappa_L(R_u(P)) = 0$.

Proof. If $R_u(P)$ is abelian, then using Table 1 we see that all the possible pairs $(G, DL)$ appear in the list of spherical Levi subgroups given in Theorem 2.42, that is $\kappa_G(G/L) = 0$. Proposition 2.40 then implies that $\kappa_L(R_u(P)) = 0$. \qed
Corollary 2.45. If \( P \) is a parabolic subgroup of \( G \) with \( R_u(P) \) abelian, then \( \kappa_L(p_u) = 0 \).

Let \( \Psi \) be the root system of \( G \) and let \( \Pi \subseteq \Psi \) be a set of simple roots of \( \Psi \). Let \( P = P_I \) (\( I \subseteq \Pi \)) be a standard parabolic subgroup of \( G \). Let \( \Psi_I \) be the root system of the standard Levi subgroup \( L_I \), i.e., \( \Psi_I \) is spanned by \( I \). Define \( \Psi_I^+ = \Psi_I \cap \Psi^+ \). For any root \( \alpha \in \Psi \) we can uniquely write \( \alpha = \alpha_I + \alpha_I' \) where \( \alpha_I = \sum_{\beta \in I} c_\beta \beta \) and \( \alpha_I' = \sum_{\beta \in \Pi \setminus I} d_\beta \beta \). We define the level of \( \alpha \) (relative to \( P \) or relative to \( I \)) to be

\[
\text{lv}(\alpha) := \sum_{\beta \in \Pi \setminus I} d_\beta,
\]

cf. [1]. Let \( d \) be the maximal level of any root in \( \Psi \). If \( 2i > d \), then

\[
A_i := \prod_{\text{lv}(\alpha) = i} U_\alpha
\]
is an abelian unipotent subgroup of \( G \). Note \( A_d \) is the centre of \( R_u(P) \). Since \( L \) normalizes each \( A_i \), we can consider \( \kappa_L(A_i) \).

Proposition 2.46. If \( P \) is a parabolic subgroup of \( G \) and \( 2i > d \), then \( \kappa_L(A_i) = 0 \).

Proof. We maintain the setup from the previous paragraph. Setting \( A_i = \prod_{\text{lv}(\alpha) = i} U_\alpha \) and \( A_i^- = \prod_{\text{lv}(\alpha) = -i} U_\alpha \), let \( H \) be the subgroup of \( G \) generated by \( A_i \), \( A_i^- \), and \( L \). Then \( H \) is reductive, with root system \( \Psi_I \cup \{ \alpha \in \Psi \mid \text{lv}(\alpha) = \pm i \} \), and \( LA_i \) is a parabolic subgroup of \( H \). Since \( A_i \) is abelian, we can invoke Proposition 2.44 to deduce that \( \kappa_L(A_i) = 0 \).

There is a natural Lie algebra analogue of Proposition 2.46: Maintaining the setup from above, for \( 2i > d \) we see that \( a_i := \bigoplus_{\text{lv}(\alpha) = i} g_\alpha \) is an abelian subalgebra of \( g \). Since \( \text{Lie} U_\alpha = g_\alpha \) for all \( \alpha \in \Psi \), we have \( \text{Lie} A_i = a_i \). Thanks to [14, Cor. 1.4], we obtain the following consequence of Proposition 2.46.

Corollary 2.47. If \( P \) is a parabolic subgroup of \( G \) and \( 2i > d \), then \( \kappa_L(a_i) = 0 \).

Remarks 2.48. (i). Corollary 2.47 was first proved, for a field of characteristic zero, in [32, Prop. 3.2], although the proof there is somewhat different from ours.

(ii). Propositions 2.44 and 2.46 suggest that that if \( A \) is an abelian subgroup of \( R_u(P) \) which is normal in \( P \), then \( \kappa_L(A) = 0 \). It is indeed the case that \( P \) acts on \( A \) with a dense orbit, see [42, Thm. 1.1]. However, this is not the case when we consider instead the action of a Borel subgroup of a Levi subgroup of \( P \) on \( A \). For example, it follows from [42, Table
1] that if $G$ is of type $A_n$, then the dimension of a maximal normal abelian subgroup $A$ of a Borel subgroup $B$ of $G$ is $i(n + 1 - i)$, where $1 \leq i \leq n$. Clearly, for $1 \neq i \neq n$ we have $\dim A > \text{rk } G$. Thus, a maximal torus of $B$ cannot act on $A$ with a dense orbit. Using [42, Table 1], it is easy to construct further examples.

3. The Classification of the Spherical Nilpotent Orbits

3.1. Height Two Nilpotent Orbits. In this subsection we show that height two nilpotent orbits are spherical. Let $e \in \mathfrak{g}$ be nilpotent and let $\lambda \in \Omega_{\mathfrak{g}_0}^*(e)$ be an associated cocharacter of $G$. Define the following subalgebra of $\mathfrak{g}$:

$$\mathfrak{g}_E := \bigoplus_{i \in \mathbb{Z}} \mathfrak{g}(2i).$$

**Proposition 3.2.** Let $e \in \mathcal{N}$, $\lambda \in \Omega_{\mathfrak{g}_0}^*(e)$, and let $\mathfrak{g}_E$ be the subalgebra of $\mathfrak{g}$ defined in (3.1).

(i) There exists a connected reductive subgroup $G_E$ of $G$ such that $\text{Lie } G_E = \mathfrak{g}_E$.

(ii) There exists a parabolic subgroup $Q$ of $G_E$ such that $\text{Lie } Q = \bigoplus_{i \geq 0} \mathfrak{g}(2i)$. Moreover, $C_G(\lambda)$ is a Levi subgroup of $Q$ and $\text{Lie } R_u(Q) = \bigoplus_{i \geq 1} \mathfrak{g}(2i)$.

**Proof.** Fix a maximal torus $T$ of $G$ such that $\lambda(k^*) \subseteq T$. Set $\Phi = \{\alpha \in \Psi \mid \langle \alpha, \lambda \rangle \in 2\mathbb{Z}\}$. Then $\mathfrak{g}_E = \bigoplus_{\alpha \in \Phi} \mathfrak{g}_\alpha$.

Then $\Phi$ is a semisimple subsystem of $\Psi$. The subgroup $G_E$ generated by $T$ and all the one-dimensional root subgroups $U_\alpha$ with $\alpha \in \Phi$ is reductive and has Lie algebra $\mathfrak{g}_E$.

Let $Q = P \cap G_E$, where $P = P_\lambda$. Since $\lambda(k^*) \subseteq T \subseteq G_E$, we see that $Q$ is a parabolic subgroup of $G_E$, see the remarks preceding Theorem 2.16. Since $\text{Lie } C_G(\lambda) = \mathfrak{g}(0)$, we have $C_G(\lambda) \subseteq Q$ and so $C_G(\lambda)$ is a Levi subgroup of $Q$. The remaining claims follow from the fact that $\text{Lie } P = \mathfrak{g}_{>0}$, the parabolic subgroup $P$ has Levi decomposition $P = C_G(\lambda)R_u(P)$ and $\text{Lie } R_u(P) = \mathfrak{g}_{>0}$.

The following discussion and Lemma 3.3 allow us to reduce the determination of the spherical nilpotent orbits to the case when $G$ is simple. Since the centre of $G$ acts trivially on $\mathfrak{g}$, we may assume that $G$ is semisimple. Let $\mathcal{G}$ be semisimple of adjoint type and $\pi : G \to \mathcal{G}$ be the corresponding isogeny. Let $e \in \mathfrak{g}$ be nilpotent and let $\bar{e} = d\pi_1(e)$. Consider the restriction of $d\pi_1$ to the nilpotent variety of $\mathfrak{g}$. Then $d\pi_1 : \mathcal{N} \to \mathcal{N}$ is a dominant $G$-equivariant morphism, where $\mathcal{N}$ is the nilpotent variety of $\text{Lie } G$ and $G$ acts on $\mathcal{N}$ via $\text{Ad } \circ \pi$. It then follows from Theorem 2.8 that $\kappa_G(G \cdot e) = \kappa_{\mathcal{G}}(\mathcal{G} \cdot \bar{e})$. We therefore may assume that $G$ is semisimple of adjoint type.

**Lemma 3.3.** Let $G$ be semisimple of adjoint type. Then $G$ is a direct product of simple groups $G = G_1G_2 \cdots G_r$. If $e \in \mathfrak{g}$ is nilpotent, then $e = e_1 + e_2 + \ldots + e_r$ for $e_i$ nilpotent in $\mathfrak{g}_i = \text{Lie } G_i$ and $\kappa_G(G \cdot e) = \sum_{i=1}^r \kappa_{G_i}(G_i \cdot e_i)$.

**Proof.** Since $G$ is semisimple of adjoint type, so that $G$ is the direct product $G = G_1G_2 \cdots G_r$ of simple groups $G_i$, we have $\text{Lie } G = \bigoplus \text{Lie } G_i$. Let $e \in \mathfrak{g}$ be nilpotent. Clearly, any element $x \in C_G(e)$ is of the form $x = x_1x_2 \cdots x_r$ where $x_i \in G_i$ and we also have that $e = e_1 + e_2 + \ldots + e_r$, where $e_i \in \mathfrak{g}_i$ and each $e_i$ must be nilpotent. We know that $\text{Ad}(x)(e) = e$ so $\text{Ad}(x_1)\text{Ad}(x_2) \cdots \text{Ad}(x_r)(e_1 + e_2 + \ldots + e_r) = e_1 + e_2 + \ldots + e_r$. For $i \neq j$ we have $\text{Ad}(x_i)(e_j) = e_j$, so $\text{Ad}(x)(e_i) = \text{Ad}(x_i)(e_i)$. Therefore, as $\text{Ad}(x_i)$ stabilizes $\mathfrak{g}_i$, we have $\text{Ad}(x_i)(e_i) = e_i$. Thus, we obtain the following decomposition $C_G(e) = C_{G_1}(e_1)C_{G_2}(e_2) \cdots C_{G_r}(e_r)$. For $B$ a
Borel subgroup of $G$ we have $B = B_1 B_2 \cdots B_r$, where each $B_i$ is a Borel subgroup of $G_i$ and $C_B(e) = C_{B_1}(e_1)C_{B_2}(e_2) \cdots C_{B_r}(e_r)$. In particular, for $B \in \Gamma_G(e)$ we have that $\dim C_B(e)$ is minimal. This implies that $\dim C_{B_i}(e_i)$ is minimal for each $i$ and so $B_i \in \Gamma_{G_i}(e_i)$. Therefore, we have

$$\kappa_G(G \cdot e) = \dim G - \dim C_B(e) - \dim B + \dim C_B(e)$$

$$= \sum_{i=1}^r \dim G_i - \sum_{i=1}^r \dim C_{G_i}(e_i) - \sum_{i=1}^r \dim B_i + \sum_{i=1}^r \dim C_{B_i}(e_i)$$

$$= \sum_{i=1}^r (\dim G_i - \dim C_{G_i}(e_i) - \dim B_i + \dim C_{B_i}(e_i))$$

$$= \sum_{i=1}^r \kappa_{G_i}(G_i \cdot e_i),$$

and the result follows. \[\square\]

**Lemma 3.4.** Let $G$ be a connected reductive algebraic group and $e \in \mathfrak{g}$ be nilpotent. If $ht(e) = 2$, then $e$ is spherical.

**Proof.** First we assume that $G$ is simple. Let $\lambda \in \Omega_G^0(e)$. Let $\mathfrak{g}_E$ be the Lie subalgebra of $\mathfrak{g}$ as defined in (3.1) and let $Q$ be the parabolic subgroup of $G_E$ as in Proposition 3.2(ii). Since $ht(e) = 2$, we have $\mathfrak{g}_E = \mathfrak{g}(-2) \oplus \mathfrak{g}(0) \oplus \mathfrak{g}(2)$. Set $L = C_G(\lambda)$. Then $\kappa_G(G \cdot e) = \kappa_L(\mathfrak{g}(2))$, by Theorem 2.33. Also, by Proposition 3.2, $\text{Lie} R_u(Q) = \mathfrak{g}(2)$. Since $R_u(Q)$ is abelian, Corollary 2.45 implies that $\kappa_L(\mathfrak{g}(2)) = 0$.

Now suppose that $G$ is reductive. Let $DG = G_1 G_2 \cdots G_r$ be a commuting product of simple groups. For $e \in \mathfrak{g}$ we have $e = e_1 + e_2 + \ldots + e_r$, where $e_i \in \mathfrak{g}_i = \text{Lie} G_i$ and each $e_i$ is nilpotent. Since $ht(e) = \max_{1 \leq i \leq r} ht(e_i)$, we have $ht(e_i) \leq ht(e) = 2$ for all $i$. Since $\kappa_G(G \cdot e) = \sum_{i=1}^r \kappa_{G_i}(G_i \cdot e_i)$, by Lemma 3.3, the result follows from the simple case just proved. \[\square\]

3.2. **Even Gradings.** Suppose that the given nilpotent element $e \in \mathfrak{g}$ satisfies $ht(e) \geq 4$. Also assume that any $\lambda \in \Omega_G^a(e)$ induces an even grading on $\mathfrak{g}$, that is $\mathfrak{g}(i, \lambda) = \{0\}$ whenever $i$ is odd. As usual we denote $\mathfrak{g}(i, \lambda)$ simply by $\mathfrak{g}(i)$.

**Lemma 3.5.** Let $e \in N$ and $\lambda \in \Omega_G^a(e)$ be as above. Then $\mathfrak{g}_{i>2}$ is non-abelian.

**Proof.** Set $ht(e) = d$. For the highest root $\check{\alpha} \in \Psi^+$ we have $\mathfrak{g}_{\check{\alpha}} \subseteq \mathfrak{g}(d)$. Write $\check{\alpha} = \alpha_1 + \alpha_2 + \ldots + \alpha_r$ as a sum of not necessarily distinct simple roots. The sequence of simple roots $\alpha_1, \alpha_2, \ldots, \alpha_r$ can be chosen so that $\alpha_1 + \alpha_2 + \ldots + \alpha_s$ is a root for all $1 \leq s \leq r$, [19, Cor. 10.2.A]. Since the grading of $\mathfrak{g}$ induced by $\lambda$ is even, for all simple roots $\alpha \in \Pi$, we have $\mathfrak{g}_\alpha \subseteq \mathfrak{g}(i)$ with $i \in \{0, 2\}$, cf. (2.37). Since $d \geq 4$, for at least one $\alpha_i$ we must have $\mathfrak{g}_{\alpha_i} \subseteq \mathfrak{g}(2)$. Let $\alpha_k$ be the last simple root in the sequence $\alpha_1, \alpha_2, \ldots, \alpha_r$ with this property. Thus, for $\beta = \alpha_1 + \alpha_2 + \ldots + \alpha_{k-1}$ we have $\mathfrak{g}_\beta \subseteq \mathfrak{g}(d-2) \subseteq \mathfrak{g}_{i>2}$. Since char $k$ is good for $G$, we have $[\mathfrak{g}_\beta, \mathfrak{g}_{\alpha_k}] = \mathfrak{g}_{\beta'}$ where $\beta' = \beta + \alpha_k$. Therefore, $\mathfrak{g}_{i>2}$ is non-abelian. \[\square\]

**Corollary 3.6.** Let $P$ be the destabilizing parabolic subgroup of $G$ defined by $e \in N$. Then $R_u(P)$ is non-abelian.
Set $p_u = \text{Lie } R_u(P)$. Because the grading of $\mathfrak{g}$ is even, $\mathfrak{g}_{\geq 2} = p_u$. Thus, by Proposition 2.40 and Theorem 2.33, we have $\kappa_G(G \cdot e) = \kappa_G(G/L)$, where $L = C_G(\lambda)$. Using the classification of the spherical Levi subgroups and the classification of the parabolic subgroups of $G$ with abelian unipotent radical, Theorem 2.42 and Lemma 2.43, we see that there are only two cases, for $G$ simple, when $R_u(P)$ is non-abelian and $L$ is spherical, namely when $G$ is of type $B_n$ and $\mathcal{DL}$ is of type $A_{n-1}$ and when $G$ is of type $C_n$ and $\mathcal{DL}$ is of type $C_{n-1}$.

Lemma 3.7. Let $G$ be of type $B_n$ or of type $C_n$. Let $e \in \mathcal{N}$ and $\lambda \in \Omega_{G}^n(e)$. Set $L = C_G(\lambda)$. If $\pi_e = [r_1^1, 2^2, \ldots]$ is the corresponding partition for $e$, then $\dim Z(L) = |\{a_i, b_i \in \mathbb{Z}_{\geq 0} | a_i + 1 = \sum_{j \geq i} r_{2j+1}, b_i + 1 = \sum_{j \geq i} r_{2j}\}|$.

Proof. Since $L$ is reductive, $L = Z(L)\mathcal{DL}$, and $Z(L) \cap \mathcal{DL}$ is finite, we have $\dim L = \dim Z(L) + \dim \mathcal{DL}$. The result follows from Proposition 2.36.

It is straightforward to deduce the following from Propositions 2.27 and 2.36.

Lemma 3.8. Let $e \in \mathcal{N}$ and $\lambda \in \Omega_{G}^n(e)$ with $ht(e) \geq 4$. Set $L = C_G(\lambda)$. If $G$ is of type $B_n$, then $\mathcal{DL}$ is not of type $A_{n-1}$ and if $G$ is of type $C_n$, then $\mathcal{DL}$ is not of type $C_{n-1}$.

Lemma 3.9. Let $e \in \mathcal{N}$ and suppose that $\lambda \in \Omega_{G}^n(e)$ induces an even grading on $\mathfrak{g}$. If $ht(e) \geq 4$, then $e$ is non-spherical.

Proof. First we observe that if $G$ is simple, then the statement follows from the facts that $R_u(P)$ is non-abelian (Corollary 3.6) and that $(G, \mathcal{DL})$ is not one of the pairs $(B_n, A_{n-1})$ or $(C_n, C_{n-1})$ (Lemma 3.8). So by Theorem 2.42 and Lemma 2.43, we see that $L$ is a non-spherical subgroup. Therefore, by Proposition 2.40, $\kappa_L(\mathfrak{g}_{\geq 2}) > 0$ and $e$ is non-spherical.

In case $G$ is reductive, we argue as in the proof of Lemma 3.4 and reduce to the simple case.

3.3. Nilpotent Orbits of Height at Least Four. Let $e \in \mathfrak{g}$ be nilpotent and let $\lambda \in \Omega_{G}^n(e)$. Let $\mathfrak{g}_E$ be the subalgebra of $\mathfrak{g}$ as defined in (3.1). Also let $G_E$ be the connected reductive algebraic group such that $\text{Lie } G_E = \mathfrak{g}_E$ and $Q$ be the parabolic subgroup of $G_E$ as in Proposition 3.2(ii).

Since $e \in \mathfrak{g}_E$ and $\lambda(k^*) \leq G_E$, it follows from [11, Thm. 1.1] that $\lambda$ is a cocharacter of $G_E$ which is associated to $e$, i.e. $\lambda \in \Omega_{G_E}^n(e)$. Moreover, for $P = P_\lambda$, we have $Q = P \cap G_E$ is the destabilizing parabolic subgroup of $G_E$ defined by $e$.

Let $ht_E(e)$ denote the height of $e \in \mathfrak{g}_E$. Now if $ht(e) \geq 4$ and $ht(e)$ is even, then $ht_E(e) = ht(e)$. The case when $ht(e) \geq 4$ and $ht(e)$ is odd is slightly more involved. First we need some preliminary results. A proof of the following can be found in [33, Prop. 2.4].

Lemma 3.10. Suppose that $\text{char } k = 0$. If $e \in \mathcal{N}$ with $ht(e)$ odd, then the weighted Dynkin diagram $\Delta(e)$ contains no “2” labels.

If $\Pi$ is a set of simple roots of $\Psi$ relative to a maximal torus $T$ which contains $\lambda(k^*)$, then for $\alpha \in \Pi$ we have

$$(3.11) \quad \mathfrak{g}_\alpha \subseteq \mathfrak{g}(i) \text{ where } i \in \{0, 1\}.$$  

To see this recall (2.37): $\text{Ad}(\lambda(t))(e_\alpha) = t^{m_\alpha}e_\alpha$, for $e_\alpha \in \mathfrak{g}_\alpha$ and $m_\alpha$ is the corresponding label of the weighted Dynkin diagram $\Delta(e)$ of $e$. Thus, by Lemma 3.10, we have $m_\alpha \in \{0, 1\}$.

Lemma 3.12. If $ht(e) = d$ odd, then $\mathfrak{g}(d - 1) \neq \{0\}$.
Proof. The result follows easily, arguing as in the proof of Lemma 3.5 and using (3.11). □

**Corollary 3.13.** If \( e \in \mathcal{N} \) with \( \text{ht}(e) \) odd, then \( \text{ht}_E(e) = \text{ht}(e) - 1 \).

In particular, we have the following conclusion.

**Corollary 3.14.** If \( e \in \mathcal{N} \) with \( \text{ht}(e) \geq 4 \), then \( \text{ht}_E(e) \geq 4 \).

Thus, by Lemma 3.9, Corollary 3.14, and the fact that \( \Omega^a_G(e) \cap Y(G_E) = \Omega^a_{G_E}(e) \) ([11, Thm. 1.1]), we have \( \kappa_L(\mathfrak{g}_{E, \geq 2}) > 0 \), where \( \mathfrak{g}_{E, \geq 2} = \bigoplus_{i \geq 1} \mathfrak{g}(2i) \) and \( L = C_G(\lambda) = C_{G_E}(\lambda) \).

**Lemma 3.15.** If a Borel subgroup \( B_L \) of \( L \) acts on \( \mathfrak{g}_{ \geq 2} \) with a dense orbit, then \( B_L \) acts on \( \mathfrak{g}_{E, \geq 2} \) with a dense orbit.

*Proof. This follows readily from Theorem 2.9. □*

Combining Lemmas 3.9, 3.15 and Corollary 3.14, we get the main result of this subsection.

**Proposition 3.16.** Let \( e \in \mathcal{N} \). If \( \text{ht}(e) \geq 4 \), then \( e \) is non-spherical.

### 3.4 Nilpotent Orbits of Height Three.

Let \( e \in \mathcal{N} \) and let \( \lambda \in \Omega^a_G(e) \). Let \( P = P(e) \) be the destabilizing parabolic subgroup defined by \( e \). Then \( P = LR_u(P) \) for \( L = C_G(\lambda) \). Let \( B_L \) be a Borel subgroup of \( L \) so that \( \lambda(k^*) \subseteq B_L \). Write \( B_L = TU_L \) for a Levi decomposition of \( B_L \), where \( U_L = R_u(B_L) \) and \( T \) is a maximal torus of \( G \) containing \( \lambda(k^*) \). Let \( \mathfrak{b}_L = \text{Lie } B_L \), \( \mathfrak{n} = \text{Lie } U_L \), and \( \mathfrak{t} = \text{Lie } T \).

**Lemma 3.17.** Let \( e \in \mathfrak{g} \) be nilpotent and \( \lambda \) be an associated cocharacter for \( e \) in \( \mathfrak{g} \). Then the following are equivalent.

(i) The nilpotent element \( e \) is spherical.

(ii) There exists \( e' \in \mathfrak{g}_{ \geq 2} \) such that \( \text{Ad}(B_L)(e') = \mathfrak{g}_{ \geq 2} \).

(iii) There exists \( e' \in \mathfrak{g}_{ \geq 2} \) such that \( \dim C_{B_L}(e') = \dim B_L - \dim \mathfrak{g}_{ \geq 2} \).

*Proof. Thanks to Theorem 2.33, \( \kappa_G(G \cdot e) = \kappa_L(\mathfrak{g}_{ \geq 2}) \). Thus (i) and (ii) are equivalent. The equivalence between (ii) and (iii) is clear. □*

Recall from Subsection 2.1 the definition of the support of a nilpotent element in \( \mathfrak{u} \).

**Lemma 3.18.** Let \( e \in \mathfrak{g}_{ \geq 2} \). If \( \text{supp}(e) \) is linearly independent, then \( \dim C_T(e) = \dim T - |\text{supp}(e)| \).

*Proof. Suppose that \( \text{supp}(e) \) is linearly independent. Then \( \dim \text{Ad}(T)(e) = |\text{supp}(e)| \), e.g. see [13, Lem. 3.2]. The desired equality follows. □*

The following is a standard consequence of orbit maps.

**Lemma 3.19.** Let \( e' \in \mathfrak{g}_{ \geq 2} \). Then \( \dim C_{B_L}(e') \leq \dim \mathfrak{c}_{B_L}(e') \) and \( \dim C_{U_L}(e') \leq \dim \mathfrak{c}_{U_L}(e') \).

In [15, Prop. 5.4], Goodwin showed that each \( U \)-orbit in \( \mathfrak{u} \) admits a unique so called minimal orbit representative, see [15, Def. 5.3]. (This depends on a suitable choice of an ordering of the positive roots compatible with the height function, cf. [15, Def. 3.1].) Moreover, a special case of [15, Prop. 7.7] gives that for \( e \) the minimal representative of its \( U \)-orbit in \( \mathfrak{u} \), we have \( C_B(e) = C_T(e)C_U(e) \). As a consequence, we readily obtain the following.

**Lemma 3.20.** Let \( e' \in \mathfrak{g}_{ \geq 2} \). Suppose that \( e' \) is the minimal representative of its \( U \)-orbit in \( \mathfrak{u} \). Then \( C_{B_L}(e') = C_T(e')C_{U_L}(e') \). In particular, \( \dim C_{B_L}(e') = \dim C_T(e') + \dim C_{U_L}(e') \).
Proposition 3.21. Let $G$ be a simple algebraic group. Table 2 below gives a complete list of the height 3 nilpotent orbits in $\mathfrak{g}$.

Proof. For the classical groups we use Proposition 2.27. By Remark 2.28, there are no height 3 nilpotent orbits in types $A_n$ and $C_n$. Using the tables in [10, §13] and (2.39), one readily determines the desired orbits when $G$ is exceptional. □

In Table 2 we either give the partition or the Bala–Carter label of the corresponding orbit, cf. [10, §13].

| Type of $G$ | Orbits |
|------------|--------|
| $A_n$      | -      |
| $B_n$      | $[1^i, 2^{2^i}, 3]$ with $i > 0$ |
| $C_n$      | -      |
| $D_n$      | $[1^i, 2^{2^i}, 3]$ with $i > 0$ |
| $G_2$      | $\tilde{A}_1$ |
| $F_4$      | $A_1 + \tilde{A}_1$ |
| $E_6$      | $3A_1$ |
| $E_7$      | $(3A_1)^{\prime}, 4A_1$ |
| $E_8$      | $3A_1, 4A_1$ |

Table 2. The nilpotent orbits of height 3.

In the next three subsections we concentrate on the height 3 orbits in types $B_n$, $D_n$, and the exceptional types, respectively.

3.5. Height Three Nilpotent Elements of $\mathfrak{so}_{2n+1}(k)$. In this subsection let $G$ be of type $B_n$ for $n \geq 3$, so $\mathfrak{g} = \mathfrak{so}_{2n+1}(k)$. The nilpotent orbits in $\mathfrak{g}$ are classified by the partitions of $2n + 1$ with even parts occurring with even multiplicity, see [22, Thm. 1.6]. By Proposition 2.27, the height 3 nilpotent orbits correspond to partitions of $2n + 1$ of the form $\pi_{r,s} = [1^s, 2^{2r}, 3]$, where $r \geq 1$, $s \geq 0$ and $2r + s + 1 = n$. Denote the corresponding nilpotent orbit by $O_{r,s}$ and a representative of such an orbit by $e_{r,s}$.

Lemma 3.22. There are precisely $\left[\frac{n-1}{2}\right]$ distinct height 3 nilpotent orbits in $\mathfrak{g}$.

Proof. By our comments above, we need to show that there are precisely $\left[\frac{n-1}{2}\right]$ partitions of $2n + 1$ of the form $\pi_{r,s}$. This is equivalent to finding all partitions of $n - 1$ of the form $[1^{s/2}, 2^r]$. Thus $r$ satisfies $1 \leq r \leq \frac{n-1}{2}$. Since $r$ is an integer, the result follows. □

Since the number $2r + 1$ appears frequently in the sequel, we set $\tilde{r} = 2r + 1$. Using [10, §13], we readily see that that $e_{r,s}$ has the following weighted Dynkin diagram:
where β

For an associated cocharacter of Lemma 3.24.

with respect to α

labeled with a “1” and that there is an odd number of simple roots between n when n is odd.

For every e

roots this information can be read off from ∆(u)

Remark 3.23. Note that in ∆(e_{r,s}) there are precisely two simple roots, α_1 and α_ν that are labeled with a “1” and that there is an odd number of simple roots between α_1 and α_ν. Also, the short simple root is labeled with a “1” if and only if s = 0, and this can only happen when n is odd.

We refer to [3, Planche II] for information regarding the root system of type B_n. Let α_1, . . . , α_n be the simple roots of Ψ+ and let

\[ β_{j,k} = α_j + \ldots + α_k \quad \text{for} \quad 1 \leq j \leq k \leq n, \]

\[ γ_{j,k} = α_j + \ldots + α_{k-1} + 2α_k + \ldots + 2α_n \quad \text{for} \quad 1 \leq j < k < n, \]

where β_{j,j} = α_j. Note that all the possible β’s and γ’s exhaust Ψ+.

For a T-stable Lie subalgebra m of u recall the definition of the set of roots Ψ(m) of m with respect to T from Subsection 2.1.

Lemma 3.24. For an associated cocharacter of e_{r,s} in g we have

(i) \( Ψ(g(2)) = \{ β_{l,m}, γ_{l,k} \mid 1 < l < k \leq \hat{r} \leq j \quad \text{and} \quad 1 < i < m \leq \hat{r} \}, \) and so \( \dim g(2) = 2r^2 - r + 2s + 1; \)

(ii) \( Ψ(g(3)) = \{ γ_{1,k} \mid k \leq \hat{r} \}, \) and so \( \dim g(3) = 2r. \)

Proof. For every δ ∈ Ψ we have that g_δ ⊆ g(i) for some i ∈ {0, ±1, ±2, ±3}. For the simple roots this information can be read off from ∆(e_{r,s}), see (2.37). Let δ = \( \sum_{α ∈ Π} c_δ,α,α \) be a positive root.

Now g_δ ⊆ g(2) if and only if \( c_δ,α_1 + c_δ,α_ν = 2. \) All of the roots listed above satisfy this condition, and no others do. Finally, g_δ ⊆ g(3) if and only if \( c_δ,α_1 + c_δ,α_ν = 3. \) All of the roots listed above satisfy this condition, and no others do.

Lemma 3.25. For an associated cocharacter of e_{r,s} in g we have

(i) \( Ψ(b_L) = \{ β_{j,k}, γ_{l,m} \mid \hat{r} < j \quad \text{or} \quad 1 < j < k < \hat{r}, \hat{r} < l < m \}. \)

(ii) \( \dim b_L = 2r^2 + s^2 + r + 1. \)

Proof. For every δ ∈ Ψ we have that g_δ ⊆ g(i) for some i ∈ {0, ±1, ±2, ±3}. As mentioned above, for the simple roots this information can be read off from ∆(e_{r,s}), see (2.37). Let δ = \( \sum_{α ∈ Π} c_δ,α,α \) ∈ Ψ+. Then g_δ ⊆ b_L if and only if \( c_δ,α_1 + c_δ,α_ν = 0. \) All of the roots listed above satisfy this condition, and no others do. Consequently, \( \dim n = 2r^2 + s^2 - r. \) Since \( \dim t = n, \) we get \( \dim b_L = 2r^2 + s^2 + r + 1. \)

It follows from Figure 1 that L is of Dynkin type A_{r-1} × B_s. Accordingly, there is a natural partition of the roots of b_L into a union of two subsets, namely the positive roots of the A_{r-1} and B_s subsystems, respectively. Thus, we have \( Ψ(b_L) = Ψ_1(b_L) ∪ Ψ_2(b_L), \)

where

\[ Ψ_1(b_L) = \{ β_{j,k} \mid 1 < j \leq k < \hat{r} \}, \]

\[ Ψ_2(b_L) = \{ β_{j,k}, γ_{l,m} \mid \hat{r} < j \leq k, \hat{r} < l < m \}. \]
Similarly, we can decompose the roots of $g_{\geq 2}$ into two sets as follows: $\Psi(g_{\geq 2}) = \Psi_1(g_{\geq 2}) \cup \Psi_2(g_{\geq 2})$, where

$$\Psi_1(g_{\geq 2}) = \{ \gamma_{j,k} \mid 1 \leq j < k \leq \hat{r} \},$$
$$\Psi_2(g_{\geq 2}) = \{ \beta_{1,j}, \gamma_{1,k} \mid \hat{r} \leq j, \hat{r} < k \}.$$

The sets $\Psi_i(b_L)$ and $\Psi_i(g_{\geq 2})$ satisfy the following property:

$$\delta \in \Psi_i(b_L), \eta \in \Psi_{3-i}(g_{\geq 2}) \Rightarrow \delta + \eta \notin \Psi, \ i \in \{1, 2\}.$$  

(3.26)

Denote by $b_i^*$ the Lie subalgebras of $b_L$ such that $\Psi(b_i^*) = \Psi_i(b_L)$ for $i = 1, 2$. For the rest of this subsection we show that the following element is a representative of the dense $B_L$-orbit in $g_{\geq 2}$; set:

$$e'_{r,s} := \sum_{j,k=0}^{r-1} (e_{\gamma_{r-j-1,\hat{r}-j}} + e_{\gamma_{1,\hat{r}-2k}}) + e_{\gamma_j} + e_{\beta_1,\hat{r}}$$

where $e_\delta \in g_\delta \setminus \{0\}$ for $\delta \in \Psi(g_{\geq 2})$.

Recall from the paragraph before Lemma 3.20 the notion of minimal $U$-orbit representatives in $u$ from [15].

**Lemma 3.27.** Each $e'_{r,s}$ is the minimal representative of its $U$-orbit in $u$, supp($e'_{r,s}$) is linearly independent, and $|\text{supp}(e'_{r,s})| = \begin{cases} 2r + 2 & \text{if } s > 0; \\ 2r + 1 & \text{if } s = 0. \end{cases}$

**Proof.** It is straightforward to check that $e'_{r,s}$ is the minimal representative of its $U$-orbit in $u$ in the sense of [15] and one easily computes $|\text{supp}(e'_{r,s})|$. Note that the root $\gamma_{1,\hat{r}+1}$ only occurs if $s > 0$.

Suppose there exist scalars $\tau_j, \xi_k, \mu$ and $\nu$ such that

$$\sum_{j=0}^{r-1} \tau_j \gamma_{r-j-1,\hat{r}-2j} + \sum_{k=0}^{r-1} \xi_k \gamma_{1,\hat{r}-2k} + \mu \gamma_{1,\hat{r}+1} + \nu \beta_1,\hat{r} = 0.$$

Since the coefficients of $\alpha_1, \alpha_2,$ and $\alpha_3$ must be zero, we have

$$\sum_{k=0}^{r-1} \xi_k + \mu + \nu = 0, \ \tau_{r-1} + \sum_{k=0}^{r-1} \xi_k + \mu + \nu = 0, \ \text{and} \ \xi_{r-1} + 2\tau_{r-1} + \sum_{k=0}^{r-1} \xi_k + \mu + \nu = 0.$$

These three equations imply that $\tau_{r-1} = 0 = \xi_{r-1}$. Continuing in this way, we see that $\tau_j = 0 = \xi_j$ for all $j$. Thus we are left to show that $\gamma_{1,\hat{r}+1}$ and $\beta_1,\hat{r}$ are linearly independent; but this is obvious.

Thanks to Lemma 3.27 it is harmless to assume that supp($e'_{r,s}$) is part of a Chevalley basis of $g$.

**Lemma 3.28.** $\dim e_{r,s}(e'_{r,s}) = \begin{cases} (s - 1)^2 & \text{if } s > 0; \\ 0 & \text{if } s = 0. \end{cases}$

**Proof.** Thanks to (3.26), we may consider the two summands $\sum_{j,k=0}^{r-1} (e_{\gamma_{r-j-1,\hat{r}-2j}} + e_{\gamma_{1,\hat{r}-2k}})$ and $e_{\gamma_j} + e_{\beta_1,\hat{r}}$ of $e'_{r,s}$ separately. Since $\gamma_{r-j-1,\hat{r}-2j} + \gamma_{1,\hat{r}-2k} \in \Psi_1(g_{\geq 2})$, we need only consider the root spaces $g_\delta$ for $\delta \in \Psi_1(b_L)$. So let $\beta_{l,m} \in \Psi_1(b_L)$. If $m = \hat{r} - 2l$ for some $0 \leq l < r$, then, by the Chevalley commutator relations, $[e_{\gamma_{r-2l+1,\hat{r}}}, g_{\beta_{l,\hat{r}-2l}}] = \nu$. If $m = 0$, then $\gamma_{r-1} = \beta_1,\hat{r}$.
showed that the height three nilpotent orbits correspond to partitions of 2
Lemma 3.32.

Next we consider the summand $e_{\gamma_1,\bar{r}+1} + e_{1,\bar{r}}$. First observe that $[n, e_{\gamma_1,\bar{r}+1}] = \{0\}$, so $c_n(e_{\gamma_1,\bar{r}+1}) = n$. Secondly, the root $e_{1,\bar{r}}$ lies in $\Psi_2(\mathfrak{g}_{\geq 2})$. Thanks to property (3.26), we need only consider roots $\delta \in \Psi_2(\mathfrak{b}_L)$. We see that the only roots $\delta \in \Psi_2(\mathfrak{b}_L)$ with $\delta + e_{1,\bar{r}} \in \Psi(\mathfrak{g}_{\geq 2})$ are of the form $e_{\bar{r}+1,j} + e_{\bar{r}+1,k}$ where $\bar{r} + 1 \leq j, k \leq n$ and $\bar{r} + 1 < k \leq n$. Again the Chevalley commutator relations imply $[\mathfrak{g} e_{\bar{r}+1,j}, e_{1,\bar{r}}] = \mathfrak{g} e_{1,j}$ and $[\mathfrak{g} e_{\bar{r}+1,k}, e_{1,\bar{r}}] = \mathfrak{g} e_{\bar{r}+1,k}$. We also observe that $e_{\bar{r},\bar{r}}$ and $\gamma_{1,m}$ for $\bar{r} + 1 < j, l$ have the property that $\beta_{1,\bar{r}+1} + \gamma_{1,m} + e_{1,\bar{r}} \notin \Psi_2(\mathfrak{g}_{\geq 2})$. All the roots above exhaust $\Psi_2(\mathfrak{b}_L)$, so we conclude that all the roots $e_{\bar{r},\bar{r}}$ and $\gamma_{1,m}$ for $\bar{r} + 1 < j, l$ of $\Psi_2(\mathfrak{b}_L)$ are all contained in $\Psi(c_n(e_{1,\bar{r}}))$. If $s > 0$, these roots form the set of positive roots of a root system of type $B_{s-1}$, there are exactly $(s-1)^2$ positive roots in a root system of type $B_{s-1}$ and so $|\Psi(c_n(e_{1,\bar{r}}))| = (s-1)^2$. Therefore, $\dim c_n(e_{1,\bar{r}}) = (s-1)^2$, clearly, if $s = 0$ then $\dim c_n(e_{1,\bar{r}}) = 0$.

**Proposition 3.29.** The $B_L$-orbit of $e_{1,\bar{r}}$ is dense in $\mathfrak{g}_{\geq 2}$.

**Proof.** Thanks to Lemma 3.17, it is sufficient to show that $\dim B_L = \dim C_{B_L}(e_{1,\bar{r}}) + \dim \mathfrak{g}_{\geq 2}$. Lemma 3.24 implies that $\dim \mathfrak{g}_{\geq 2} = 2r^2 + 2s + r + 1$ and Lemma 3.25 implies that $\dim B_L = 2r^2 + 2s + s + r + 1$. By Lemma 3.27, $e_{1,\bar{r}}$ is the minimal representative of $U$-orbit in $\mathfrak{u}$. Thus, by Lemma 3.20, we have $\dim C_{B_L}(e_{1,\bar{r}}) = \dim C_T(e_{1,\bar{r}}) + \dim C_U(e_{1,\bar{r}})$. Consequently, Lemmas 3.19, 3.27, and 3.28 imply that, for $s > 0$, $\dim C_{B_L}(e_{1,\bar{r}}) \leq n - 2r - 2 + (s-1)^2 = s^2 - s$. So

$$\dim C_{B_L}(e_{1,\bar{r}}) + \dim \mathfrak{g}_{\geq 2} \leq s^2 - s + 2r^2 + r + 2s + 1 = \dim B_L.$$

This clearly implies $\dim B_L = \dim C_{B_L}(e_{1,\bar{r}}) + \dim \mathfrak{g}_{\geq 2}$. Similarly, if $s = 0$, we get $\dim B_L = \dim C_{B_L}(e_{1,\bar{r}}) + \dim \mathfrak{g}_{\geq 2}$.

**Corollary 3.30.** $\dim C_{B_L}(e_{1,\bar{r}}) = s(s-1)$.

Finally, from Lemma 3.17 we obtain

**Corollary 3.31.** If $G$ is of type $B_n$ and $e \in \mathcal{N}$ with $ht(e) = 3$, then $e$ is spherical.

3.6. Height Three Nilpotent Elements of $\mathfrak{so}_{2n}(k)$. Assume for this subsection that $G$ is of type $D_n$ for $n \geq 4$, so $\mathfrak{g} = \mathfrak{so}_{2n}$. We know that the nilpotent orbits in $\mathfrak{g}$ are classified by the partitions of $2n$ with even parts occurring with even parity, see [22, Thm. 1.6]. We showed that the height three nilpotent orbits correspond to partitions of $2n$ of the form $\tau_{r,s} = [1^{2r+1}, 2r, 3]$ where $r \geq 1, s \geq 0$ and $2r + s + 2 = n$, see Proposition 2.27. Similarly to the $B_n$ case, we denote the corresponding orbit by $O_{r,s}$ and a representative of such an orbit by $e_{r,s}$. Because the proofs of the results in this subsection are virtually identical to the ones in Subsection 3.5, they are omitted.

**Lemma 3.32.** There are precisely $\frac{n-2}{2}$ distinct height 3 nilpotent orbits in $\mathfrak{g}$.

Using [10, §13], we can easily calculate that for $s > 0$, $e_{r,s}$ has the weighted Dynkin diagram $\Delta(e_{r,s})$ as shown in Figure 2 below.

Similarly, when $s = 0$, the labelling of $\Delta(e_{r,0})$ is shown in Figure 3 below.

**Remark 3.33.** Note that there is always an odd number of “0” labels between the first and second “1” labels in $\Delta(e_{r,s})$. If $s > 0$, then there are $s + 1$ “0” labels to the right of the second “1” label. Finally, $s = 0$ only if $n$ is even.
We refer to [3, Planche IV] for information regarding the root system of type $D_n$. We use the following notation for the positive roots $\Psi^+$. Let $\alpha_1, \ldots, \alpha_n$ be the set of simple roots of $\Psi^+$ and let

$$
\begin{align*}
\beta_{j,k} &= \alpha_j + \ldots + \alpha_k \text{ for } 1 \leq j \leq k \leq n \text{ not } j = n - 1, k = n, \\
\beta_j &= \alpha_j + \ldots + \alpha_{n-2} + \alpha_n \text{ for } 1 \leq j \leq n - 2, \\
\gamma_{j,k} &= \alpha_j + \ldots + \alpha_{k-1} + 2\alpha_k + \ldots + 2\alpha_{n-2} + \alpha_{n-1} + \alpha_n \text{ for } 1 \leq j < k < n - 2.
\end{align*}
$$

Here we again use the convention $\beta_{j,j} = \alpha_j$. Note that all the possible $\beta$’s and $\gamma$’s exhaust $\Psi^+$.

Next we consider the structure of the abelian Lie subalgebra $g_{\geq 2} = g(2) \oplus g(3)$.

**Lemma 3.34.** An associated cocharacter for $e_{r,s}$ affords the following.

1. $\Psi(g(2)) = \begin{cases} 
\{\beta_{1,j}, \beta_1, \gamma_{l,k}, \gamma_{1,m} \mid 1 < l < k \leq \hat{r} \leq j, \hat{r} < m\} & \text{if } s > 0; \\
\{\beta_{1, n-1}, \beta_1, \beta_{n, n}, \gamma_{j,k} \mid 2 \leq i < \hat{r}, 1 < j < k < \hat{r}\} & \text{if } s = 0.
\end{cases}$

   In particular, $\dim g(2) = 2r^2 - r + 2s + 2$.

2. $\Psi(g(3)) = \begin{cases} 
\{\gamma_{l, k} \mid k \leq \hat{r}\} & \text{if } s > 0; \\
\{\beta_{1,n}, \gamma_{1,k} \mid 2 \leq k < \hat{r}\} & \text{if } s = 0.
\end{cases}$

   In particular, $\dim g(3) = 2r$.

Next we look at the structure of the Lie subalgebra $b_L$ of $g(0)$.

**Lemma 3.35.** An associated cocharacter for $e_{r,s}$ affords the following.

$$
\Psi(b_L) = \begin{cases} 
\{\beta_1, \beta_{j,k}, \gamma_{l,m} \mid \hat{r} < j \text{ or } 1 < j \leq k < \hat{r}, \hat{r} < i, \hat{r} < l < m\} & \text{if } s > 0; \\
\{\beta_{j,k} \mid 1 < j \leq k < \hat{r}\} & \text{if } s = 0.
\end{cases}
$$

In particular, $\dim b_L = 2r^2 + s^2 + r + 2s + 2$.

Similarly to the $B_n$ case, the roots of $b_L$ naturally form two distinct subsets, namely the roots whose support lies strictly to the left of the second “1” label of the weighted Dynkin
diagram and those whose support lies strictly to the right of the second “1” label on the weighted Dynkin diagram. More precisely, we have $Ψ(b_L) = Ψ_1(b_L) ∪ Ψ_2(b_L)$ where

$Ψ_1(b_L) = \{ β_{j,k} \mid 1 < j < k < \widehat{r} \}$,

$Ψ_2(b_L) = \{ β_{j,k}, β_i, γ_{l,m} \mid \widehat{r} < j < k, \widehat{r} < i, \widehat{r} < l < m \}$.

Again we partition the roots of $g_{≥2}$ into two distinct subsets. More precisely, we write $Ψ(g_{≥2}) = Ψ_1(g_{≥2}) ∪ Ψ_2(g_{≥2})$, where for $s ≥ 1$, we define

$Ψ_1(g_{≥2}) = \{ γ_{j,k} \mid 1 ≤ j < k ≤ \widehat{r} \}$,

$Ψ_2(g_{≥2}) = \{ β_1, β_{1,j}, γ_{1,k} \mid \widehat{r} ≤ j, \widehat{r} < k \}$,

and for $s = 0$, we define

$Ψ_1(g_{≥2}) = \{ γ_{j,k} \mid 1 ≤ j < k ≤ \widehat{r} \}$,

$Ψ_2(g_{≥2}) = \{ β_1, β_{1,n-1}, β_{j,n}γ_{1,k} \mid j ≤ \widehat{r} < k \}$.

Again, we have the following property of these sets:

$δ \in Ψ_i(b_L), η \in Ψ_{3-i}(g_{≥2}) \Rightarrow δ + η \notin Ψ, i \in \{1, 2\}$.

For $s > 1$, set

$e'_{r,s} := \sum_{j,k=0}^{r-1} (e_{γ_{j-1,1}, \widehat{r}-j} + e_{γ_{1,\widehat{r}-2k}}) + e_{γ_{1,\widehat{r}+1}} + e_{b_1, \widehat{r}} \in g_{≥2},$

for $s = 1$, set

$e'_{r,1} := \sum_{j,k=0}^{r-1} (e_{γ_{j-1,1}, \widehat{r}-j} + e_{γ_{1,\widehat{r}-2k}}) + e_{b_1, n} + e_{b_1, \widehat{r}} \in g_{≥2},$

and for $s = 0$, set

$e'_{r,0} := \sum_{j,k=1}^{r-1} (e_{γ_{j-1,1}, \widehat{r}-j} + e_{γ_{1,\widehat{r}-2k}}) + e_{b_1, n} + e_{b_1, n-1} + e_{b_{n-2}, n} + e_{b_1} \in g_{≥2}.$

**Lemma 3.37.** With the notation as above, we have $\mid \text{supp}(e'_{r,s}) \mid = 2r + 2$, $\text{supp}(e'_{r,s})$ is linearly independent, and $\text{dim}(c_n(e'_{r,s})) = s(s-1)$.

**Proposition 3.38.** The $B_L$-orbit of $e'_{r,s}$ is dense in $g_{≥2}$.

**Corollary 3.39.** If $G$ is of type $D_n$ and $e \in N$ with $\text{ht}(e) = 3$, then $e$ is spherical.

3.7. **Height Three Nilpotent Elements of the Exceptional Lie Algebras.** We fix an ordering of the roots $α_1, \ldots, α_r$ of $Ψ(g_{≥2})$ such that $α_i < α_j$ for $i < j$. Define the subalgebra $m_i$ of $g_{≥2}$ by setting $m_i = \bigoplus_{j=1}^{i} g_{aj}$ and the quotient $q_i$ by $q_i = g_{≥2}/m_i$ for $0 ≤ i ≤ r$. Let $B$ be a Borel subgroup of $G$ such that $g_{≥2} \subseteq \text{Lie} R_u(B) = u$. Note that each $q_i$ is a $B$-module.

The computer programme, DOOBS, devised by S.M. Goodwin allows us to determine whether $B$ acts on $g_{≥2}$ with a dense orbit. For details of the GAP4 ([12]) computer algebra program of Goodwin, we refer the reader to [13] and [16]. Working inductively, starting with $i = 0$, at each stage of the algorithm, DOOBS determines a representative $x_i + m_i$, with
supp($x_i$) linearly independent of a dense $B$-orbit on $q_i$, or decides that $B$ does not act on $q_i$ with a dense orbit.

DOOBS also keeps a record of the primes for which $\dim_p c_u(x_i + m_{i+1}) > \dim_0 c_u(x_i + m_{i+1})$, where $\dim_p c_u(x_i + m_{i+1})$ and $\dim_0 c_u(x_i + m_{i+1})$ denote the dimension of $c_u(x_i + m_{i+1})$ over a field of characteristic $p$ and characteristic 0 respectively, see Remark 3.2 in [13]. For these primes we cannot conclude that $B$ acts on $g_{\geq 2}$ with a dense orbit. If DOOBS determines that $B$ acts on $g_{\geq 2}$ with a dense orbit, then it calculates a representative of the dense orbit and a list of primes for which the result is not necessarily valid.

There is a variant of DOOBS called DOOBSLevi, see [16]. This program considers a parabolic subgroup $P = LR_u(P)$ and determines whether a Borel subgroup $B_L$ of $L$ acts on an ideal of Lie $R_u(P)$ with a dense orbit. The algorithm used to determine whether $B_L$ acts on an ideal with a dense orbit is essentially the same as the DOOBS algorithm, with $B_L$ replacing $B$. DOOBSLevi also records the primes for which its conclusions are not necessarily valid.

Let $e \in N$ of height 3 and let $\lambda$ be a cocharacter of $G$ that is associated to $e$. We use the same numbering of the positive roots as in GAP4. Table 3 below lists the roots whose root subgroups together with $T$ generate the Levi subgroup $C_G(\lambda)$ and we also list the roots whose root subspaces generate $g_{\geq 2}$ (as a $B$-submodule of $g$) for the 7 cases of height three nilpotent orbits for the simple exceptional groups, see Proposition 3.21. These are determined by means of the weighted Dynkin diagrams.

| Type of $G$ | Bala–Carter Label | Generators for $L$ | Generators for $g_{\geq 2}$ |
|-------------|------------------|------------------|------------------|
| $G_2$       | $\tilde{A}_1$    | $\alpha_2$       | $\alpha_4$       |
| $F_4$       | $A_1 + \tilde{A}_1$ | $\Pi \setminus \{\alpha_4\}$ | $\alpha_{16}$ |
| $E_6$       | $3A_1$           | $\Pi \setminus \{\alpha_4\}$ | $\alpha_{24}$ |
| $E_7$       | $(3A_1)'$        | $\Pi \setminus \{\alpha_3\}$ | $\alpha_{37}$ |
| $E_7$       | $4A_1$           | $\Pi \setminus \{\alpha_2, \alpha_7\}$ | $\alpha_{30}, \alpha_{53}$ |
| $E_8$       | $3A_1$           | $\Pi \setminus \{\alpha_7\}$ | $\alpha_{74}$ |
| $E_8$       | $4A_1$           | $\Pi \setminus \{\alpha_2\}$ | $\alpha_{69}$ |

Table 3. Height Three Nilpotent Orbits in the Exceptional Lie Algebras.

The height 3 cases for the exceptional groups were analyzed using the DOOBSLevi algorithm. It turns out that there are no characteristic restrictions in these cases:

**Lemma 3.40.** If $G$ is simple of exceptional type and $e \in N$ with $\text{ht}(e) = 3$, then $e$ is spherical.

Corollaries 3.31 and 3.39 combined with Lemma 3.40 give the following result.

**Proposition 3.41.** Let $G$ be a connected reductive algebraic group and let $e \in N$. If $\text{ht}(e) = 3$, then $e$ is spherical.
Proof. If $G$ is simple, then the statement follows from Corollaries 3.31 and 3.39 and Lemma 3.40. In the general case we argue as in Lemma 3.4 to reduce to the simple case.

3.8. The Classification. Our main classification theorem now follows readily from Lemma 3.4 and Propositions 3.16 and 3.41.

**Theorem 3.42.** Let $G$ be a connected reductive algebraic group. Suppose that char $k$ is a good prime for $G$. Then a nilpotent element $e \in \mathfrak{g}$ is spherical if and only if $ht(e) \leq 3$.

**Remark 3.43.** Let $G$ be a simple algebraic group and let char $k$ be a good prime for $G$. Then the spherical nilpotent orbits are given in Table 4. We present the orbits by listing the corresponding partition in the classical cases or by giving the corresponding Bala–Carter label for the exceptional groups.

| Type of $G$ | Spherical Orbits |
|-------------|------------------|
| $A_n$       | $[1^i, 2^j]$     |
| $B_n$       | $[1^i, 2^{2i}]$, or $[1^i, 2^{2i}, 3]$ with $i \geq 0$ |
| $C_n$       | $[1^i, 2^j]$     |
| $D_n$       | $[1^i, 2^{2i}]$, or $[1^i, 2^{2i}, 3]$ with $i \geq 0$ |
| $G_2$       | $A_1$ or $\tilde{A}_1$ |
| $F_4$       | $A_1$, $\tilde{A}_1$, or $A_1 + \tilde{A}_1$ |
| $E_6$       | $A_1$, $2A_1$, or $3A_1$ |
| $E_7$       | $A_1$, $2A_1$, $(3A_1)'$, $(3A_1)'$, or $4A_1$ |
| $E_8$       | $A_1$, $2A_1$, $3A_1$, or $4A_1$ |

**Table 4.** The spherical nilpotent Orbits for $G$ simple.

**Remark 3.44.** Using the fact that in good characteristic a Springer map affords a bijection between the set of unipotent $G$-conjugacy classes and the set of nilpotent $G$-orbits (see [45]), Theorem 3.42 also gives a classification of the spherical unipotent classes in $G$. Here we define the height of a unipotent element $u$ of $G$ as the height of the image of $u$ in $\mathcal{N}$ under a Springer isomorphism.

4. Applications and Complements

Here we discuss some applications of the main result and some further consequences.

4.1. Spherical Distinguished Nilpotent Elements. Recall that a nilpotent element $e \in \mathcal{N}$ is distinguished in $\mathfrak{g}$ if every torus contained in $C_G(e)$ is contained in the centre of $G$. For now we assume that $G$ is simple, so $e$ is distinguished in $\mathfrak{g}$ if and only if any torus contained in $C_G(e)$ is trivial and hence $C_G(e)^{\circ}$ is unipotent. Further recall that $\kappa_G(G \cdot e) = \kappa_G(G/C_G(e)^{\circ})$, cf. equation (2.15). Since $C_G(e)^{\circ}$ is connected and unipotent, it is contained in the unipotent
radical $U$ of a Borel subgroup $B = TU$ of $G$. Let $B^− = TU^−$ be the unique opposite Borel subgroup to $B = TU$ relative to $T$, see [20, §26.2]. Consequently, $B^− \cap C_G(e)^o \subseteq B^− \cap U = \{1\}$. Thus, by equation (2.11), we have $κ_G(G/C_G(e)^o) = \dim G - \dim C_G(e)^o - \dim B^− = \dim U - \dim C_G(e)$, or equivalently, $κ_G(G \cdot e) = |Ψ^+| - \dim C_G(e)$. We summarize what we have just shown.

**Proposition 4.1.** Let $e ∈ N$ be a distinguished nilpotent element. Then

$$κ_G(G \cdot e) = |Ψ^+| - \dim C_G(e).$$

**Remark 4.2.** Proposition 4.1 was first observed by Panyushev for a field of characteristic zero in [32, Cor. 2.4].

If $G$ is a simple classical group, then the distinguished nilpotent elements are given as follows, see Lemmas 4.1 and 4.2 in [22].

**Lemma 4.3.** Let $e ∈ N$ and let $π_e$ be the corresponding partition of $\dim V$.

(i) If $G = SL(V)$, then $e$ is distinguished if and only if $π_e = [\dim V]$.

(ii) If $G = Sp(V)$, then $e$ is distinguished if and only if $π_e$ consists only of distinct even parts.

(iii) If $G = SO(V)$, then $e$ is distinguished if and only if $π_e$ consists only of distinct odd parts.

**Corollary 4.4.** If $G = SO(V)$ and $e ∈ N$ is spherical and distinguished, then $ht(e) = 2$.

**Proof.** Thanks to Proposition 3.21, the height 3 nilpotent elements have partitions of the form $π = [1^r, 2^r, 3]$, where $r > 0$. Thus such a partition has even parts and so is not distinguished. So if $e$ is spherical and distinguished, then $ht(e) = 2$.

Proposition 2.27 and Lemma 4.3 imply the following result.

**Proposition 4.5.** Let $e ∈ N$ be distinguished and $π_e$ be the corresponding partition of $\dim V$.

(i) If $G = SL(V)$, then $ht(e) = 2$ if and only if $π_e = [2]$.

(ii) If $G = Sp(V)$, then $ht(e) = 2$ if and only if $π_e = [2]$.

(iii) If $G = SO(V)$, then $ht(e) = 2$ if and only if $π_e = [3]$ or $π_e = [1, 3]$.

**Theorem 4.6.** If $G$ is a simple algebraic group and $e ∈ N$ is spherical and distinguished, then $G$ is of type $A_1$.

**Proof.** For $G$ simple classical, Proposition 4.5 implies that $G$ is of type $A_1$. For $G$ of exceptional type it follows from Remark 3.43 and the tables in [10, §13] that there are no nilpotent orbits in $g$ that are both spherical and distinguished. □

4.2. **Orthogonal Simple Roots and Spherical Nilpotent Orbits.** In [33, Thm. 3.4], Panyushev proved that if the characteristic of $k$ is zero, then $e ∈ N$ is spherical if and only if there exist pairwise orthogonal simple roots $α_1, α_2, \ldots, α_t$ in $Π$ such that $G \cdot e$ contains an element of the form $\sum_{i=1}^t e_{α_i}$ where $e_{α_i} ∈ g_{α_i} \setminus \{0\}$. By pairwise orthogonal we mean that $⟨α_i, α_j⟩ = 0$ for $i \neq j$. In this subsection we show that this is also the case if the characteristic of $k$ is good for $G$.

**Lemma 4.7.** Let $DG$ be of type $A_1^t$ for some $t ≥ 1$. Then there is precisely one distinguished nilpotent orbit in $N$.  

28
Proof. Since the nilpotent orbits of $G$ in $\mathfrak{g}$ are precisely the nilpotent orbits of $D\mathcal{G}$ in Lie $D\mathcal{G}$, we may assume that $G$ is semisimple. Thus, $G = G_1G_2\cdots G_r$ and each $G_i$ is of type $A_1$. There is precisely one distinguished nilpotent orbit when $G_i$ is of type $A_1$: the unique non-zero nilpotent orbit. Also $G \cdot e$ is distinguished in $\mathfrak{g}$ if and only if $G_i \cdot e_i$ is distinguished in $\mathfrak{g}_i = \text{Lie} \, G_i$ for all $i$, where $e = e_1 + \ldots + e_r$ and $e_i \in \mathfrak{g}_i$ is nilpotent. \hfill $\square$

Lemma 4.8. Let $e \in \mathcal{N}$ and $S$ be a maximal torus of $C_G(e)$. Then $D\mathcal{C}_G(S)$ is of type $A_t^1$ for some $t \geq 1$ if and only if there exist pairwise orthogonal simple roots $\alpha_1, \alpha_2, \ldots, \alpha_t$ in $\Pi$ such that $G \cdot e$ contains an element of the form $\sum_{i=1}^t e_{\alpha_i}$, where $e_{\alpha_i} \in \mathfrak{g}_{\alpha_i} \setminus \{0\}$.

Proof. Suppose that $D\mathcal{C}_G(S)$ is of type $A_t^1$. Let $\alpha_1, \ldots, \alpha_t$ be simple roots of $\Phi$, where $\Phi$ is the root system of $C_G(S)$ relative to a maximal torus $T$ of $C_G(S)$. As $D\mathcal{C}_G(S)$ is of type $A_t^1$, the roots $\alpha_1, \ldots, \alpha_t$ are pairwise orthogonal. Clearly, $e \in \text{Lie} \, C_G(S) = \mathfrak{c}_G(S)$ and $e$ is distinguished in $\mathfrak{c}_G(S)$, see Proposition 2.17. By Lemma 4.7, an element of the form $\sum_{i=1}^t e_{\alpha_i}$ is also distinguished in $\mathfrak{c}_G(S)$ and there is precisely one distinguished nilpotent orbit in $\mathfrak{c}_G(S)$. Thus, $e$ and $\sum_{i=1}^t e_{\alpha_i}$ are in the same $C_G(S)$-orbit, hence they are in the same $G$-orbit. So $G \cdot e$ contains an element of the desired form.

Conversely, suppose that there exist pairwise orthogonal simple roots $\alpha_1, \alpha_2, \ldots, \alpha_t \in \Psi$ such that $G \cdot e$ contains an element of the form $e' = \sum_{i=1}^t e_{\alpha_i}$. Let $H$ be the subgroup of $G$ generated by $\{T, U_{i\alpha_i} \mid 1 \leq i \leq t\}$, where $T$ is as in the previous paragraph. Then $D\mathcal{C}_G(S)$ is of type $A_t^1$. By construction, $e'$ is distinguished in $\mathfrak{h}$. By Proposition 2.17, $H$ is of the form $C_G(S')$, where $S'$ is a maximal torus of $C_G(e')$. Thus, $D\mathcal{C}_G(S')$ is of type $A_t^1$. Since $e$ and $e'$ are $G$-conjugate, so are $C_G(e)$ and $C_G(e')$, as well as $S$ and $S'$. Finally, we get that $C_G(S)$ and $C_G(S')$ are $G$-conjugate. The result follows. \hfill $\square$

Lemma 4.9. If $e \in \mathcal{N}$ is spherical, then $D\mathcal{C}_G(S)$ is of type $A_t^1$ for some $t \geq 1$.

Proof. Let $\lambda$ be a cocharacter of $G(G(S))$ that is associated to $e$, i.e. $\lambda \in \Omega_{\mathcal{C}_G(S)}^\circ(e)$. Then, since $\text{Lie} \, C_G(S) = \mathfrak{c}_G(S)$, it follows from [11, Cor. 3.21] that $\lambda \in \Omega_{\mathcal{C}_G(S)}^\circ(e)$. As $e$ is spherical in $\mathfrak{g}$, we have $ht(e) \leq 3$, by Theorem 3.42. As $\lambda \in \Omega_{\mathcal{C}_G(S)}^\circ(e)$, we also have $ht(e) \leq 3$ when we regard $e$ as an element of $\mathfrak{c}_G(S)$. Thus, again by Theorem 3.42, $e$ is spherical in $\mathfrak{c}_G(S)$. So $e$ is distinguished and spherical in $\mathfrak{c}_G(S)$ and so $D\mathcal{C}_G(S)$ is of type $A_t^1$, by Theorem 4.6. \hfill $\square$

In order to prove the reverse implication of Lemma 4.9 we first need to consider the group $C_G(S)$. If $G$ is classical, then the structure of $C_G(S)$ can be determined from the partition $\pi_e$ corresponding to $e$; see [22, §4.8] for the following result.

Lemma 4.10. Let $G$ be simple classical and $e \in \mathcal{N}$ with corresponding partition $\pi_e$.

(i) If $G$ is of type $A_n$ and $\pi_e = [1^{r_1}, 2^{r_2}, \ldots]$, then $D\mathcal{C}_G(S)$ is of type $\prod_{i \geq 1} A_{r_i-1}^1$.

(ii) If $G$ is of type $B_n$ and $\pi_e = [1^{2s_1+1}, 2^{2s_2}, 3^{2s_3}, \ldots]$, where $s_i \geq 0$ and $\epsilon_i \in \{0, 1\}$, then $D\mathcal{C}_G(S)$ is of type $\prod_{i \geq 1} A_{s_i - 1}^{\epsilon_i} \times B_m$, where $2m + 1 = \sum_{i \neq 0} \epsilon_i$.

(iii) If $G$ is of type $C_n$ and $\pi_e = [1^{2s_1}, 2^{2s_2+1}, 3^{2s_3}, \ldots]$, where $s_i \geq 0$ and $\epsilon_i \in \{0, 1\}$, then $D\mathcal{C}_G(S)$ is of type $\prod_{i \geq 1} A_{s_i - 1}^{\epsilon_i} \times C_m$, where $2m = \sum_{i \neq 0} \epsilon_i$.

(iv) If $G$ is of type $D_n$ and $\pi_e = [1^{2s_1+1}, 2^{2s_2}, 3^{2s_3}, \ldots]$, where $s_i \geq 0$ and $\epsilon_i \in \{0, 1\}$, then $D\mathcal{C}_G(S)$ is of type $\prod_{i \geq 1} A_{s_i - 1}^{\epsilon_i} \times D_m$, where $2m = \sum_{i \neq 0} \epsilon_i$.

Lemma 4.11. If $G$ is simple classical and $D\mathcal{C}_G(S)$ is of type $A_t^1$, then $e$ is spherical.
Proof. First suppose that $G$ is of type $A_n$. Since $DC_G(S)$ is of type $A_1^r$, it follows from Lemma 4.10 that $r_i = 0$ for all $i \geq 3$. Thus $\pi_e = [1^{r_1}, 2^{r_2}]$ and so $e$ is spherical, by Remark 3.43.

Let $G$ be of type $B_n$. Since $DC_G(S)$ is of type $A_1^r$, it follows from Lemma 4.10 that $s_i = 0$ for $i \geq 3$ and $m \leq 1$, so $2m + 1 \leq 3$. Since $2m + 1$ is a sum of distinct odd integers, we either have $2m + 1 = 1$ or $2m + 1 = 3$. Thus $\pi_e = [1^{2s_1 + 1}, 2^{s_2}]$ or $\pi_e = [1^{2s_1}, 2^{s_2}, 3]$ and so $e$ is spherical, again by Remark 3.43.

Let $G$ be of type $C_n$. Since $DC_G(S)$ is of type $A_1^r$, it follows from Lemma 4.10 that $s_i = 0$ for $i \geq 3$ and $m \leq 1$, so $2m \leq 2$. Since $2m$ is a sum of distinct even integers, we either have $2m = 0$ or $2m = 2$. Thus $\pi_e = [1^{2s_1}, 2^{s_2}]$ or $\pi_e = [1^{2s_1}, 2^{s_2} + 1]$ and so, by Remark 3.43, $e$ is spherical.

Finally, let $G$ be of type $D_n$. Since $DC_G(S)$ is of type $A_1^r$, it again follows from Lemma 4.10 that $s_i = 0$ for $i \geq 3$ and $m \leq 1$, so $2m \leq 4$. Since $2m$ is a sum of distinct odd integers, we either have $2m = 0$ or $2m = 1 + 3$. Thus $\pi_e = [1^{2s_1}, 2^{s_2}]$ or $\pi_e = [1^{2s_1 + 1}, 2^{s_2}, 3]$ and so, by Remark 3.43, $e$ is spherical.

All that remains is to check the exceptional cases. The Bala–Carter label of $e \in \mathcal{N}$ gives the Dynkin type of a Levi subgroup $L$ of $G$ such that $e$ is distinguished in Lie $DL$. By Proposition 2.17, such a Levi subgroup is the centralizer of a maximal torus of $C_G(e)$. Thus, the Bala–Carter label gives the type of $DC_G(S)$. It follows from the tables in [10, §13] and Remark 3.43 that any nilpotent orbit with Bala–Carter label $A_1^r$ is spherical. We summarize this in Table 5 below.

| Type | Bala–Carter Label | Height | Type | Bala–Carter Label | Height |
|------|-------------------|--------|------|-------------------|--------|
| $G_2$ | $A_1$ | 2 | $E_7$ | $A_1$ | 2 |
|      | $\bar{A}_1$ | 3 | $E_7$ | $2A_1$ | 2 |
| $F_4$ | $A_1$ | 2 | $E_7$ | $(3A_1)^c$ | 2 |
|      | $\bar{A}_1$ | 2 | $E_7$ | $(3A_1)'$ | 3 |
| $F_4$ | $A_1 + \bar{A}_1$ | 3 | $E_7$ | $4A_1$ | 3 |
| $E_6$ | $A_1$ | 2 | $E_8$ | $A_1$ | 2 |
|      | $2A_1$ | 2 | $E_8$ | $2A_1$ | 2 |
| $E_6$ | $3A_1$ | 3 | $E_8$ | $3A_1$ | 3 |
|      | $4A_1$ | 3 | $E_8$ | $4A_1$ | 3 |

Table 5. Orbits in Exceptional Lie Algebras with $DC_G(S)$ of Type $A_1^r$.

**Lemma 4.12.** If $G$ is a simple exceptional algebraic group and $DC_G(S)$ is of type $A_1^r$, then $e$ is spherical.

**Lemma 4.13.** Let $e \in \mathcal{N}$. If $DC_G(S)$ is of type $A_1^r$, then $e \in \mathfrak{g}$ is spherical.

Proof. For $G$ simple, the result follows from Lemmas 4.11 and 4.12. In the general case let $DG = G_1G_2 \cdots G_r$ be a commuting product of simple groups and $e = e_1 + e_2 + \ldots + e_r$, where $e_i \in \mathfrak{g}_i = \text{Lie } G_i$ and each $e_i$ is nilpotent. A maximal torus $S$ of $C_G(e)$ is of the form
Lemma 4.16. valid in good characteristic. However, the forward implication of this equivalence is still spherical. This is proved by means of the fact that an orbit $G \cdot e$ is spherical if and only if $ad(e)^4 = 0$, see [32, Cor. 2.2]. Unfortunately, this equivalence is no longer true in positive characteristic, see Example 4.17. However, the forward implication of this equivalence is still valid in good characteristic.

Lemma 4.15. Let $G$ be a simple classical algebraic group and $e \in \mathcal{N}$.

(i) Let $e$ be a nilpotent matrix in $\mathfrak{sl}_n$ or $\mathfrak{sp}_n$. Then $e$ is spherical if and only if $e^2 = 0$.

(ii) Let $e$ be a nilpotent matrix in $\mathfrak{so}_n$. Then $e$ is spherical if and only if the rank of $e^2$ is at most one.

Proof. Let $e$ be a nilpotent matrix in $\mathfrak{sl}_n$ or $\mathfrak{sp}_n$. If $e$ is spherical, then $\pi_e = [1^j, 2^i]$, for appropriate $i$ and $j$, see Remark 3.43. By considering the corresponding Jordan blocks for $\pi_e$, we see that $e^2 = 0$. Conversely, if $e^2 = 0$, then $e$ is conjugate to an element $e'$ with partition $\pi_{e'} = [1^j, 2^i]$ and so $e$ is spherical, again by Remark 3.43.

Let $e$ be a nilpotent matrix in $\mathfrak{so}_n$. If $e$ is spherical, then $\pi_e = [1^j, 2^i]$ or $\pi_e = [1^j, 2^i, 3]$, for appropriate $i$ and $j$, see Remark 3.43. By considering the corresponding Jordan blocks for $\pi_e$, we see that either $e^2 = 0$ or $e^2$ has partition $\pi_{e^2} = [1^k, 2]$. Thus the rank of $e^2$ is either 0 or 1. Conversely, if the rank of $e^2$ is at most 1, then $e$ is conjugate to an element $e'$ with partition $\pi_{e'} = [1^j, 2^i]$ or $\pi_{e'} = [1^j, 2^i, 3]$ and so $e$ is spherical, again by Remark 3.43.

In [34] and [35], D.I. Panyushev and the second author gave a classification of the spherical ideals of $\mathfrak{b} = \text{Lie } B$ contained in $\mathfrak{b}_u = \text{Lie } R_u(B)$, where $B$ is a Borel subgroup of $G$ in characteristic 0. An ideal $\mathfrak{c}$ of $\mathfrak{b}$ is called \textit{spherical} if its $G$-saturation $G \cdot \mathfrak{c} = \{ x \cdot e \mid x \in G, e \in \mathfrak{c} \}$ is a spherical $G$-variety. First in [34, Cor. 2.4] it is proved that if $\mathfrak{a}$ is an Abelian ideal of $\mathfrak{b}$, then $\mathfrak{a}$ is spherical. In [35, Prop. 4.1 and Thm. 4.2] it is proved that there are non-abelian spherical ideals only if $G$ is not simply-laced, that is if the Dynkin diagram of $G$ has a multiple bond.

Theorem 2.3 in [34] states that any $G$-orbit meeting an abelian ad-nilpotent ideal $\mathfrak{a}$ is spherical. This is proved by means of the fact that an orbit $G \cdot e$ is spherical if and only if $\text{ad}(e)^4 = 0$, see [32, Cor. 2.2]. Unfortunately, this equivalence is no longer true in positive characteristic, see Example 4.17. However, the forward implication of this equivalence is still valid in good characteristic.

Lemma 4.16. If $e \in \mathcal{N}$ is spherical, then $\text{ad}(e)^4 = 0$. 

}\]
Corollary 4.19. It is straightforward to get the sphericity of $G$. Theorem 4.18. Let $a$ be an abelian ad-nilpotent ideal of $b$. Remark 4.20. We note that Theorem 4.18 and Corollary 4.19 do in fact hold in arbitrary characteristic, cf. [42, Thm. 1.1].

Remark 4.21. If $c$ is a spherical ideal of $b$, then clearly $B$ acts on $c$ with a finite number of orbits. However, the converse does not hold. There are many additional instances when $B$ acts on a given ideal $c$ of $b$ only with a finite number of orbits, e.g. see the results in [17] and [23].

4.4. A Geometric Characterization of Spherical Orbits. In this subsection we describe a formula characterizing spherical $G$-orbits in a simple algebraic group $G$ in terms of elements of the Weyl group $W$ of $G$ that is proved in [8, Thm. 1]. For $x \in G$ the conjugacy class $G \cdot x$ is spherical if $G \cdot x$ is a spherical variety. While this characterization in loc. cit. is based on case by case arguments, recently, G. Carnovale [9, Thm. 2] gave a proof of this result which is free of case by case considerations and applies in good odd characteristic. Using the arguments from [8] combined with our classification of the spherical unipotent nilpotent orbits, Remark 3.44, we can generalize this formula to good characteristic.
Let $G$ be simple and suppose that $p$ is good for $G$. Fix a Borel subgroup $B$ of $G$. Let $W$ be the Weyl group of $G$ and let $BwB$ be the $(B, B)$-double coset of $G$ containing $w \in W$. The following was shown in [8] in an argument independent of the characteristic of the underlying field: Suppose that $O$ is a conjugacy class in $G$ which intersects the double coset $BwB$ so that $\dim O = \ell(w) + \text{rk}(1 - w)$ holds. Then $O$ is spherical. Here $\text{rk}(1 - w)$ denotes the rank of the linear map $1 - w$ in the standard representation of $W$ and $\ell$ is the usual length function of $W$ with respect to a distinguished set of generators of $W$. Conversely, let $O$ be a spherical conjugacy class in $G$ and let $BwB$ be the $(B, B)$-double coset containing the dense $B$-orbit in $O$. Then $\dim O = \ell(w) + \text{rk}(1 - w)$, see [9, Thm. 2]. Consequently, this gives a geometric characterization of the spherical conjugacy classes in $G$. For proofs we refer the reader to [8] and [9]. Observe that as a consequence of the finiteness of the Bruhat decomposition of $G$ and the fact that any $(B, B)$-double coset and any conjugacy class of $G$ are irreducible subvarieties of $G$, for a given conjugacy class $O$ in $G$ there is a unique $w \in W$ such that $O \cap BwB$ is dense in $O$.

**Theorem 4.22.** ([8, Thm. 1]) Let $O$ be a conjugacy class in $G$ and let $w \in W$ be such that $O \cap BwB$ is dense in $O$. Then $O$ is spherical if and only if $\dim O = \ell(w) + \text{rk}(1 - w)$.

4.5. **Bad Primes and Spherical Nilpotent Orbits.** Finally, we briefly discuss the situation when the characteristic of $k$ is bad for $G$. In this case the classification of the nilpotent orbits in $N$ is different from that in good characteristic, see [10, §5.11]. However, there is still only a finite number of nilpotent orbits, [18]. Unfortunately, our methods do not allow us to give a classification of the spherical nilpotent orbits in this case. For, in our classification we made use of the height of a nilpotent orbit, where the height is defined via an associated cocharacter. However, it is not known whether associated cocharacters always exist for all nilpotent elements in bad characteristic, cf. [22, §5.14, §5.15].

In principle one can still determine whether a given nilpotent orbit is spherical by a case by case analysis. Next we give two examples of this. In particular, we show that Theorem 4.14 fails in bad characteristic in general. These examples show that there can be additional spherical nilpotent orbits in bad characteristic.

**Examples 4.23.** (i). Let $G$ be of type $B_2$ and char $k = 2$. Let $\alpha$ and $\beta$ be the simple roots of $\Psi$ with $\alpha$ the long root. Let $e = e_{\alpha + \beta} + e_{\alpha + 2\beta}$. According to [22, §5.14] the centralizer $C_G(e)$ is the unipotent radical of a Borel subgroup of $G$. Thus, by Lemma 2.12, $C_G(e)$ is a spherical subgroup of $G$ and so $e$ is spherical. Note that the $G$-orbit of $e$ does not contain an element of the form $e_\alpha$ or $e_\beta$, but $e$ is still spherical. Thus, Theorem 4.14 is no longer true in bad characteristic. Moreover, $e$ is distinguished in $g$, [22, §5.14]. This shows that Theorem 4.6 can also fail for bad characteristic.

(ii). Let $G$ be of type $G_2$ and char $k = 3$. Let $\alpha$ and $\beta$ be the simple roots of $\Psi$ with $\alpha$ the long root. Let $e = e_{\alpha + 2\beta} + e_{2\alpha + 3\beta}$. According to [22, §5.15], the centralizer $C_G(e)$ is the unipotent radical of a Borel subgroup of $G$. Thus, by Lemma 2.12, $C_G(e)$ is a spherical subgroup of $G$ and so $e$ is spherical. Again, the $G$-orbit of $e$ does not contain an element of the form $e_\alpha$ or $e_\beta$, but $e$ is spherical. Again, $e$ is distinguished in $g$, [22, §5.15].

**Acknowledgements:** The first author acknowledges funding by the EPSRC. We are grateful to S.M. Goodwin for providing the relative version DOOBSLevi of his program DOOBS that was used in Subsection 3.7 to determine the sphericity of the nilpotent orbits.
of height 3 for the exceptional cases and for very helpful discussions and improvements of the paper. We would also like to thank the referee for suggesting some improvements.
