Multi-electron and multi-muon production have been measured at high transverse momentum in electron-proton collisions at HERA. Good overall agreement is found with the Standard Model predictions, dominated by photon-photon interactions. Events are observed with a di-electron mass above 100 GeV, a domain where the Standard Model prediction is low.

1. Introduction

The measurement of rare processes provides a unique method to search for new physics. At HERA, two experiments (H1 and ZEUS) study electron-proton collisions with a center of mass energy of 300 to 320 GeV. In this paper we shortly describe the first measurement of multi-electron and multi-muon production at high transverse momentum ($P_T$) in $ep$ collisions at HERA.

2. Multi-lepton Processes

Within the Standard Model (SM) the production of multilepton events in $ep$ collisions is possible mainly through photon-photon interactions, where quasi-real photons radiated from the incident electron and proton interact to produce a pair of leptons $\gamma \gamma \rightarrow \ell^+ \ell^-$. The GRAPE Monte Carlo generator interfaced to full detector simulation has been used to simulate multi-lepton production. This generator is based on the full electro-weak matrix element calculation at tree level. The scattered proton or its remnants is treated in three phase space regions: elastic, quasielastic and inelastic.

The main experimental backgrounds to multi-electron production are processes where, in addition to a true electron, one or more fake electrons may be reconstructed from the final state particles. The dominant contribution is expected from Neutral Current Deep Inelastic Scattering (NC-DIS) where a fake electron from the hadrons or a radiated photon is selected together with the scattered electron. Elastic Compton scattering can also contribute if the high $P_T$ photon is misidentified as an electron. Background for multi-muon events are processes where fake muons are reconstructed from isolated hadrons. This contribution is negligible.

3. Measurement of multi-electron events

Both the H1 and ZEUS experiments are complex detectors with very good lepton identification capabilities. The electron identification is based on calorimetric information together with tracking conditions for efficient background rejection.

Electrons are measured by both H1 and ZEUS in a large acceptance range $5^\circ < \theta_e < 175^\circ$, where $\theta_e$ is the electron polar angle measured with respect to the outgoing proton direction. The electron energy measured from calorimetric information has to be above 5 GeV. This energy threshold is increased in H1 analysis to 10 GeV for electrons candidates with $\theta_e < 20^\circ$. The ZEUS analysis requires the electron energy above 10 GeV for $\theta_e < 164^\circ$. The electron candidates have to be isolated from other calorimetric deposits. In the central region defined by $20^\circ < \theta_e < 150^\circ$ for the H1 analysis and $17^\circ < \theta_e < 164^\circ$ for the ZEUS
Table 1

Observed and predicted multi-electron event rates for all selected events and for events with masses $M_{12} > 100$ GeV as function of the number of identified electrons. The prediction errors for the H1 analysis include model uncertainties and experimental systematical errors added in quadrature. For ZEUS analysis, the predicted rates are shown with the statistical errors of the Monte Carlo only.

| Selection                  | DATA   | SM      | GRAPE   | NC-DIS + Compton |
|----------------------------|--------|---------|---------|------------------|
| **H1 115 pb$^{-1}$**       | 20$^\circ$ < $\theta^{e1,2}$ < 150$^\circ$, $P_T^{e1} > 10$ GeV, $P_T^{e2} > 5$ GeV | 105     | 118.2 ± 12.8 | 93.3 ± 11.5 | 25.0 ± 5.5 |
| Visible 2e                 | 16     | 21.6 ± 3.0 | 21.5 ± 3.0 | 0.1 ± 0.1 |
| Visible 3e, $M_{12} > 100$ GeV | 3      | 0.25 ± 0.05 | 0.21 ± 0.04 | 0.04 ± 0.03 |
| Visible 3e, $M_{12} > 100$ GeV | 3      | 0.23 ± 0.04 | 0.23 ± 0.04 | 0.00 ± 0.00 |
| **ZEUS 130 pb$^{-1}$**     | 17$^e$ < $\theta^{e1,2}$ < 167$^e$, $P_T^{e2} > 10$ GeV, $E^{e2} > 10$ GeV | 266     | 21.3 ± 3.9 | 182.2 ± 1.2 | 31.7 ± 3.7 |
| Visible 2e                 | 191    | 34.7 ± 5.0 | 34.7 ± 5.0 | - |
| Visible 3e, $M_{12} > 100$ GeV | 2      | 0.77 ± 0.08 | 0.47 ± 0.05 | 0.30 ± 0.07 |
| Visible 3e, $M_{12} > 100$ GeV | 0      | 0.37 ± 0.04 | 0.37 ± 0.04 | - |

The selection of multi-electron events is based on the requirement of two central electrons with large energy or transverse momentum. Both H1 and ZEUS analysis require the first central electron to have transverse momentum above 10 GeV. The second central electron is required to have $P_T^{e2} > 5$ GeV ($E^{e2} > 10$ GeV) in H1 (ZEUS) analysis. Any other electron identified is also counted and the selected events are classified by the number of identified electrons in the event.

The results of H1 and ZEUS analyses are presented in the table. The H1 analysis on an event sample corresponding to 115 pb$^{-1}$ measured 121 multi-electron events, while ZEUS, with an integrated luminosity of 130 pb$^{-1}$ detected 217 such events. The di-electron sample is dominated by the signal with a 15-20% contribution from the background. In the tri-electron sample, the background contribution is negligible. Both H1 and ZEUS observations are in good agreement with the predicted rates. The main difference between H1 and ZEUS acceptances for the signal is due to different angular range for the central electrons.

The distributions of the invariant mass of the two highest $P_T$ electrons are shown in figures 1 and 2. Data are in good overall agreement with the Standard Model prediction. A few events with masses $M_{12} > 100$ GeV are observed in a region where the standard model prediction is low. H1 measured 3 di-electron events for 0.25 expected. ZEUS observed 2 di-electron events for 0.77 expected. In the tri-electron sample, H1 observed 3 events with $M_{12} > 100$ GeV for an expectation of 0.23 while ZEUS do not observe events in that mass region where the expectation is 0.37. For the high mass di-electron events, the transverse momenta of the two electrons is also large (above 50 GeV). The topology of the observed tri-electron high-mass events is different: the transverse momenta of the two highest $P_T$ electrons is lower (around 30 GeV) and the high mass value is associated with a larger polar opening angle between the two electrons (“forward-backward” topology).

4. Measurement of multi-muon events

Muons are identified using central tracker reconstructed tracks, calorimetric deposits and muon chamber signals. A search for multi-muon events has been performed by the H1 and ZEUS
Figure 1. Distribution of the invariant mass $M_{12}$ of the two highest $P_T$ electrons for the H1 analysis. Events classified as di-electrons (left) and tri-electrons (right) are shown.

No event with two muons at high mass $M_{\mu\mu} > 100$ GeV is observed by either experiment. Starting from the 3 high mass di-electron events observed by H1 the expected observation should be of the order of one di-muon event with $M_{12} > 100$ GeV, due to the lower efficiency and luminosity in the multi-muon channel. The expected increase in luminosity at HERA II will improve the knowledge of the high mass region and allow a better comparison between electron and muon channels.

Figure 3 presents the visible cross section measured by H1 as a function of the invariant mass of the muon pair compared to the Standard Model prediction. Backgrounds and also other sources of muon pair production like heavy hadron decays are negligible. Very good agreement with the Standard Model prediction is observed up to 80 GeV over a four order of magnitude decrease in the cross section. The integrated cross section in the visible phase space has been measured to be $46.5 \pm 4.7$ pb in good agreement with the prediction of 46.2 pb.

The H1 collaboration has measured separate cross-section for inelastic muon pair production. Inelastic events contain hadrons attributed to the proton dissociation detected in the main calorimeter or in the forward components of the detector. The inelastic cross section has been measured by H1 to be $20.8 \pm 3.3$ pb in agreement with the expected cross section of 21.5 pb.
5. Conclusions

Events with two or three visible leptons (electrons or muons) have been measured for the first time in electron-proton collisions by H1 and ZEUS experiments. Good overall agreement with the Standard Model prediction is observed. In the multi-electron analysis, several events with invariant mass of the two highest $P_T$ electrons $M_{12} > 100$ GeV have been observed. Multi-muon events have also been detected and the differential cross section has been measured and found in very good agreement with the Standard Model. No event with two muons at high mass $M_{\mu\mu} > 100$ GeV is observed by either experiment. The increase in luminosity expected at HERA II will improve the knowledge of multi-lepton production at high transverse momenta and high mass.
