ABSTRACT: We generalize the unifying relations for tree amplitudes to the 1-loop Feynman integrands. By employing the 1-loop CHY formula, we construct differential operators which transmute the 1-loop gravitational Feynman integrand to Feynman integrands for a wide range of theories, including Einstein-Yang-Mills theory, Einstein-Maxwell theory, pure Yang-Mills theory, Yang-Mills-scalar theory, Born-Infeld theory, Dirac-Born-Infeld theory, bi-adjoint scalar theory, non-linear sigma model, as well as special Galileon theory. The unified web at 1-loop level is established. Under the well known unitarity cut, the 1-loop level operators will factorize into two tree level operators. Such factorization is also discussed.

1 Introduction

The past decades have revealed amazing relations and common structures within amplitudes of gauge and gravity theories, such as the Kawai-Lewellen-Tye (KLT) relations [1], Bern-Carrasco-Johansson (BCJ) color-kinematics duality [2–4], which are invisible upon inspecting the traditional Feynman rules. These progresses hint the existence of some long hidden unifying relations for on-shell amplitudes. The marvelous unity was first spelled out in [9] by using the Cachazo-He-Yuan (CHY) formulations [5–9]. In the CHY framework, different theories are defined by different CHY integrands, while they found that CHY integrands for a wide range of theories can be generated from the CHY integrand for gravity theory,\(^1\) through the so called compactifying, squeezing, as well as the generalized dimensional reduction procedures [9]. More recently, similar unifying relations for on-shell tree amplitudes of a

\(^1\)Here the gravity theory has to be understood in a generalized version, i.e., Einstein gravity theory couples to a dilaton and two-forms.
variety of theories, based on constructing some Lorentz and gauge invariant differential operators, were proposed by Cheung, Shen and Wen [10]. By acting these differential operators, one can transmute the physical amplitude of a theory into the one of another theory. The similarity between two unified webs implies the underlying connection between two approaches. This connection has been established in [11–13], by applying differential operators to CHY integrals for different theories.

It is natural to ask if these unifying relations can be generalized to the loop level. This interesting question was first considered in [12], which showed the strong evidence for the existence of unifying relations at 1-loop level. Motivated by the experience at the tree level, we study this issue by considering the 1-loop CHY formula in this paper. The 1-loop CHY formula can be obtained via either the underlying ambitwistor string theory [14–19, 21], or the forward limit method [22–25]. In this paper, we focus on the latter one. Our basic idea can be summarized as follows. Suppose the tree amplitudes of theories $A$ and $B$ are connected by the operator $O$ as $A_B = O A_A$, we seek the 1-loop level operator $O_1$ satisfying $O_1 F A_A = F O_1 A_A$, where the operator $F$ denotes taking the forward limit. Since the 1-loop Feynman integrands are obtained via the forward limit as $I_A = (1/\ell^2) F A_A$ and $I_B = (1/\ell^2) F A_B$, one can conclude that the operator $O_1$ transmutes the Feynman integrand in the desired manner $I_B = O_1 I_A$.

The elegant structure of the tree and 1-loop CHY formulae offers some advantages, which allow us to realize the above idea conveniently. The tree amplitudes and the 1-loop Feynman integrands in the CHY formulae are formulated as contour integrals over auxiliary variables as

$$A = \int d\mu I^L I^R, \quad I = \frac{1}{\ell^2} \int d\mu' F (I^L I^R) = \frac{1}{\ell^2} \int d\mu' (F I^L)(F I^R),$$

(1.1)

respectively, where the auxiliary variables are localized by constraints from the so-called scattering equations. In these formulae, different theories are characterized by the so called CHY integrands $I^L I^R$ and $F (I^L I^R)$. The tree level operators in [10–13] are commutable with the CHY contour integrals $\int d\mu$, while the 1-loop level operators $O_1$ which will be constructed in this paper are commutable with the contour integral $\int d\mu'$. Therefore, transmuting a Feynman integrand is equivalent to transmuting the associated CHY integrand. More explicitly, if two Feynman integrands $I_A$ and $I_B$ are related by an operator $O_1$ as $I_A = O_1 I_B$, analogous relation $F (I^L I^R)_B = O_1 F (I^L I^R)_A$ for CHY integrands must hold, and vice versa. Similarly, at the tree level, the connection $A_A = O A_B$ is equivalent to $(I^L I^R)_B = O (I^L I^R)_A$. Thus, one can study the unifying relations systematically by acting operators on CHY integrands. Furthermore, the partial integrands $I^L$ and $I^R$ carry two independent sets of polarization vectors $\{\epsilon_i\}$ and $\{\tilde{\epsilon}_i\}$ respectively, and so do $(F I^L)$ and $(F I^R)$. Thus one can define two classes of operators, where $O_1^{\epsilon}$ and $O^\epsilon$ depend on polarization vectors in $\{\epsilon_i\}$, while $O_1^{\tilde{\epsilon}}$ and $O^{\tilde{\epsilon}}$ depend on those in $\{\tilde{\epsilon}_i\}$. Then, for our purpose, it is sufficient to find the operator $O_1^{\epsilon}$ which satisfies $O_1^{\epsilon} F I^L = F O^{\epsilon} I^L$ (or equivalently the operator $O_1^{\tilde{\epsilon}}$ satisfies $O_1^{\tilde{\epsilon}} F I^R = F O^{\tilde{\epsilon}} I^R$). We will construct the 1-loop differential operators $O_1^{\epsilon}$ which satisfy the above requirement by considering the effects of the operators $O^\epsilon$ at the tree level.
Using the method discussed above, we will find the 1-loop differential operators which transmute the 1-loop GR Feynman integrand to the Feynman integrands of a large verity of theories including pure Yang-Mills (YM) theory, Einstein-Yang-Mills (EYM) theory, Einstein-Maxwell (EM) theory, Born-Infeld (BI) theory, Dirac-Born-Infeld (DBI) theory, special Galileon (SG) theory, non-linear sigma model (NLSM), as well as bi-adjoint scalar (BAS) theory, and establish the unified web at 1-loop level.

Under the well known unitarity cut, the 1-loop Feynman integrand factorizes into two on-shell tree amplitudes. Suppose the Feynman integrands of two theories are related as $I_B = O \circ I_A$, under the unitarity cut, the 1-loop level operator $O \circ$ should also factorize into two tree level operators, due to the assumption $A_B = O \circ A_A$ which serve as the foundation of our method. This property exhibits another connection between the tree and 1-loop operators. We will also discuss such factorization of the 1-loop level differential operators.

The remainder of this paper is organized as follows. In section 2, we give a brief introduction to the tree level and 1-loop level CHY formulae, the forward limit approach, as well as the tree level differential operators, which are crucial for subsequent discussions. In section 3, we construct the 1-loop level differential operator which transmutes the 1-loop GR Feynman integrand to the YM Feynman integrand, and transmutes the YM Feynman integrand to the BAS Feynman integrand. Then, in section 4 we apply the similar idea to other theories, and find operators which relate the GR Feynman integrand to Feynman integrand of a special case of the single trace EYM, the Feynman integrands of BI, NLSM, SG, EM and the extended EM that photons carry flavors, as well as DBI. The factorization of 1-loop level differential operators under the unitarity cut will be studied in section 5. Finally, we end with a summary and discussions in section 6, provide the 1-loop level unified web of different theories.

2 Background

For reader’s convenience, in this section we rapidly review the necessary background. In subsection 2.1, we give a brief introduction to the CHY formula at the tree level. Then, in subsection 2.2, we review the forward limit method, as well as the CHY formula at the 1-loop level. Finally, the tree level differential operators, which link the tree level amplitudes of a wide range of theories together, will be introduced in subsection 2.3.

2.1 Tree level CHY formula

In the CHY framework, tree amplitudes for $n$ massless particles in arbitrary dimensions arise from a multi-dimensional contour integral over the moduli space of genus zero Riemann surfaces with $n$ punctures, $\mathcal{M}_{0,n}$ [5–9], formulated as

$$A_n = \int d\mu_n \mathcal{I}^L(\{k, \epsilon, z\})\mathcal{I}^R(\{k, \tilde{\epsilon}, \tilde{z}\}),$$

(2.1)

which possesses the Möbius $\text{SL}(2, \mathbb{C})$ invariance. Here $k_i, \epsilon_i$ and $z_i$ are the momentum, polarization vector, and puncture location for $i$th external particle, respectively. The measure part is defined as

$$d\mu_n = \frac{d^n z}{\text{vol SL}(2, \mathbb{C})} \prod_i \delta(\xi_i).$$

(2.2)
The $\delta$-functions impose the scattering equations
\begin{equation}
\mathcal{E}_i \equiv \sum_{j \in \{1, 2, \ldots, n\} \setminus \{i\}} \frac{k_i \cdot k_j}{z_{ij}} = 0, \tag{2.3}
\end{equation}
where $z_{ij} \equiv z_i - z_j$. The scattering equations define the map from the punctures on the moduli space $\mathcal{M}_{0,n}$ to vectors on the light cone, and fully localize the integral on their solutions. The measure part is universal, while the integrand in (2.1) depends on the theory under consideration. For any theory known to have a CHY representation, the corresponding integrand can be split into two parts $I^L$ and $I^R$, as can be seen in (2.1). Either of them are weight-2 for each variable $z_i$ under the Möbius transformation. In table 1, we list the tree level CHY integrands which will be used in this paper [9].

| Theory | $I^L(k, \epsilon, z)$ | $I^R(k, \epsilon, z)$ |
|--------|---------------------|---------------------|

Table 1. Form of the integrands for various theories.

We now explain building blocks appearing in table 1 in turn. There are five kinds of $n \times n$ matrixes
\begin{align}
A_{ij} &= \begin{cases} k_i \cdot k_j \over z_{ij} & i \neq j, \\ 0 & i = j \end{cases}, & B_{ij} &= \begin{cases} \epsilon_i \cdot \epsilon_j \over z_{ij} & i \neq j, \\ 0 & i = j \end{cases}, \\
C_{ij} &= \begin{cases} k_i \cdot \epsilon_j \over z_{ij} & i \neq j, \\ - \sum_{l=1, l \neq j}^{n} \frac{k_l \cdot \epsilon_j}{z_{lj}} & i = j \end{cases} \tag{2.4}
\end{align}

For theories contain gauge or flavor groups, we only show the integrands for color-ordered partial amplitudes instead of full ones.
and
\[ X_{ij} = \begin{cases} \frac{1}{z_{ij}} & i \neq j, \\ 0 & i = j. \end{cases} \] (2.5)
where \( \delta_{ij} \) forbids the interaction between particles with different flavors. To clarify the dimension, we denote the \( n \times n \) matrixes \( X \) and \( \mathcal{X} \) as \([X]_n\), \([\mathcal{X}]_n\). The \( 2n \times 2n \) antisymmetric matrix \( \Psi \) is given by
\[ \Psi = \left( \begin{array}{cc} A & C \\ -C^T & B \end{array} \right). \] (2.6)

The definition of \( \Psi \) can be generalized to the \((2a+b) \times (2a+b)\) case \([\Psi]_{a,b}\) as
\[ [\Psi]_{a,b} = \left( \begin{array}{c} A_{(a+b)\times(a+b)} \\ -C_{a\times(a+b)}^T \\ B_{a\times a} \end{array} \right), \] (2.7)
where \( A \) is a \((a+b) \times (a+b)\) matrix, \( C \) is a \((a+b) \times a\) matrix, and \( B \) is an \( a \times a\) matrix. The definitions of elements of \( A, B \) and \( C \) are the same as before.

The notation \( \text{Pf} \) stands for the polynomial called Pfaffian. For a \( 2n \times 2n \) skew symmetric matrix \( S \), Pfaffian is defined as
\[ \text{Pf} S = \frac{1}{2^n n!} \sum_{\sigma \in S_{2n}} \text{sgn}(\sigma) \prod_{i=1}^{2n} a_{\sigma(2i-1),\sigma(2i)}. \] (2.8)
where \( S_{2n} \) is the permutation group of \( 2n \) elements and \( \text{sgn}(\sigma) \) is the signature of \( \sigma \). More explicitly, let \( \Pi \) be the set of all partitions of \( \{1, 2, \cdots, 2n\} \) into pairs without regard to the order. An element \( \alpha \) in \( \Pi \) can be written as
\[ \alpha = \{(i_1, j_1), (i_2, j_2), \cdots, (i_n, j_n)\}, \] (2.9)
with \( i_k < j_k \) and \( i_1 < i_2 < \cdots < i_n \). Now let
\[ \sigma_\alpha = \begin{pmatrix} 1 & 2 & 3 & 4 & \cdots & 2n-1 & 2n \\ i_1 & j_1 & i_2 & j_2 & \cdots & i_n & j_n \end{pmatrix} \] (2.10)
be the associated permutation of the partition \( \alpha \). If we define
\[ S_\alpha = \text{sgn}(\sigma_\alpha) a_{i_1j_1} a_{i_2j_2} \cdots a_{i_nj_n}, \] (2.11)
then the Pfaffian of the matrix \( S \) is given as
\[ \text{Pf} S = \sum_{\alpha \in \Pi} S_\alpha. \] (2.12)
From the (2.12) one can observe that in every term \( S_\alpha \) of the Pfaffian, each number of \( \{1, 2, \cdots, 2n\} \), as the subscript of the matrix element, will appear once and only once. This observation is simple but useful for latter discussions.

With the definition of Pfaffian provided above, the reduced Pfaffian of the matrix \( \Psi \) is defined as \( \text{Pf}' \Psi = \frac{(-1)^{i+j}}{z_{ij}} \text{Pf} \Psi_{i,j} \), where the notation \( \Psi_{i,j} \) means the rows and columns \( i, j \)
of the matrix $\Psi$ have been deleted (with $1 \leq i, j \leq n$). It can be proved that this definition is independent of the choice of $i$ and $j$. Analogous notation holds for $\mathbf{Pf}^I A$. The reduced Pfaffian $\mathbf{Pf}[\Psi]_{a,b,c}$ is defined in the same manner. With the definition of the reduced Pfaffian, one can observe that each polarization vector $\epsilon_i$ appears once and only once in each term of the reduced Pfaffian.

Finally, the Parke-Taylor factor for ordering $\sigma$ is given as

$$PT(\sigma_1, \ldots, \sigma_n) = \frac{1}{z_{\sigma_1}z_{\sigma_2}z_{\sigma_3} \cdots z_{\sigma_{n-1}}z_{\sigma_n}z_{\sigma_1}}, \tag{2.13}$$

it implies the color ordering $\sigma_1, \ldots, \sigma_n$ for the partial amplitude. Throughout this paper, we use $\sigma_1, \ldots, \sigma_m$ to denote the color ordering among $m$ elements $\sigma_i$.

### 2.2 Forward limit method and 1-loop CHY formula

The 1-loop CHY formula can be obtained via the so called forward limit method. The forward limit is reached as follows:

- Consider a $(n + 2)$-point tree amplitude $A(k_1, \ldots, k_n, k_+, k_-)$ including $n$ massless legs with momenta in $\{k_1, \ldots, k_n\}$ and two massive legs with $k_+^2 = k_-^2 = m^2$;
- Take the limit $k_\pm \to \pm \ell$, and glue the two corresponding legs together;
- Sum over all allowed internal states of the internal particle with loop momenta $\ell$, such as polarization vectors or tensors, colors, flavors, and so on.\(^3\)

Roughly speaking, the obtained object, times the factor $1/\ell^2$ as

$$\frac{1}{\ell^2} F A(k_1, \ldots, k_n, k_+^{h+}, k_-^{h-}) = \frac{1}{\ell^2} \sum_h A(k_1, \ldots, k_n, \ell^{h+}, -\ell^{h-}), \tag{2.14}$$

contributes to the 1-loop Feynman integrand $I(k_1, \ldots, k_n)$. Here we introduced the forward limit operator $F$ to denote the operation of taking forward limit. In this paper, we denote the 1-loop Feynman integrands by $I$, to distinguish them from the CHY integrands $I$.

Now we introduce the relation among $F A(k_1, \ldots, k_n, k_+^{h+}, k_-^{h-})$ and $I(k_1, \ldots, k_n)$, in the CHY framework. For the tree amplitude $A(k_1, \ldots, k_n, k_+, k_-)$ with two massive legs $k_+^2 = k_-^2 = m^2$, there are $(n + 2)$ scattering equations, given as

$$\mathcal{E}_i \equiv \sum_{j \in \{1, \ldots, n\} \setminus \{i\}} \frac{k_i \cdot k_j}{z_{ij}} + \frac{k_+ \cdot k_i}{z_{i+}} + \frac{k_- \cdot k_i}{z_{i-}} = 0, \quad i \in \{1, \ldots, n\}$$

$$\mathcal{E}_+ \equiv \sum_{j=1}^{n} \frac{k_+ \cdot k_j}{z_{+j}} + \frac{k_+ \cdot k_+ + m^2}{z_{+-}} = 0, \quad \mathcal{E}_- \equiv \sum_{j=1}^{n} \frac{k_- \cdot k_j}{z_{-j}} + \frac{k_- \cdot k_- + m^2}{z_{-+}} = 0. \tag{2.15}$$

\(^3\)For theories include gauge or flavor groups, we only discuss the color ordered partial amplitudes in this paper, thus the summations over colors or flavors are hidden. We will encounter the summation over flavors when considering the EMf theory that photons carry flavors.
In the limit \( k_{\pm} \to \pm \ell \), these equations behave as

\[
E_i \equiv \sum_{j \in \{1, 2, \ldots, n\} \setminus \{i\}} \frac{k_i \cdot k_j}{z_{ij}} + \frac{k_i \cdot \ell}{z_{i+}} - \frac{k_i \cdot \ell}{z_{i-}} = 0, \quad i \in \{1, \ldots, n\}
\]

These 1-loop scattering equations yield the massive propagators \( 1/((\ell + K)^2 - \ell^2) \) in the loop, rather than the desired massless ones \( 1/(\ell + K)^2 \). However, these massive propagators relate to the massless ones through the well known partial fraction identity

\[
\frac{1}{D_1 \cdots D_m} = \sum_{i=1}^{m} \frac{1}{D_i} \left[ \prod_{j \neq i} \frac{1}{D_j - D_i} \right],
\]

which implies

\[
\frac{1}{\ell^2 (\ell + K_1)^2 (\ell + K_1 + K_2)^2 \cdots (\ell + K_1 + \cdots + K_{m-1})^2} \approx \frac{1}{\ell^2} \sum_{i=1}^{m} \left[ \prod_{j \neq i}^{i+m-2} \frac{1}{(\ell + K_i + \cdots + K_j)^2 - \ell^2} \right].
\]

For each individual term at the r.h.s. of the above relation, we have shifted the loop momentum without alternating the result of Feynman integral. Here \( \approx \) means the l.h.s. and r.h.s. are not equivalent to each other at the integrand level, but are equivalent at the integration level. We emphasize that the l.h.s. of (2.18) is the standard propagators in the loop for an individual diagram, contributes to \( I(k_1, \cdots, k_n) \), while each term at the r.h.s. can be obtained via the forward limit method.

Thus, to construct the correct 1-loop Feynman integrand \( I(k_1, \cdots, k_n) \) via the 1-loop scattering equations in (2.16), one need to cut each propagator in the loop once, and sum over all resulting objects, as required by the partial fraction relation (2.18). For the amplitude without any color ordering, this requirement is satisfied automatically when summing over all possible Feynman diagrams, thus we have

\[
I(k_1, \cdots, k_n) = \frac{1}{\ell^2} \mathcal{F} A(k_1, \cdots, k_n, k_{+}^{h+}, k_{-}^{h-}).
\]

For the color ordered amplitude, this requirement is satisfied by summing over color orderings cyclically, namely

\[
I(\sigma_1, \cdots, \sigma_n) = \frac{1}{\ell^2} \sum_{i \in \{1, \ldots, n\}} \mathcal{F} A(\sigma_i, \cdots, \sigma_{i-1}, -).
\]

The integrands \( I(k_1, \cdots, k_n) \) and \( I(\sigma_1, \cdots, \sigma_n) \) provided in (2.19) and (2.20) are not the original 1-loop Feynman integrands written via Feynman rules, since the loop momenta have been shifted in each term. But we still regard them as Feynman integrands, since they are equivalent to the original ones at the integration level. In other words, the 1-loop

\[
\text{(2.16)}
\]

\[
\text{(2.17)}
\]

\[
\text{(2.18)}
\]

\[
\text{(2.19)}
\]

\[
\text{(2.20)}
\]
Feynman integrand should be understood as a class of integrands which give the same result after doing the integration.

As an equivalent interpretation, the forward limit method can also be understood from the dimensional reduction point of view, as studied in [23].

Let us take a brief look at the CHY integrand at the 1-loop level. In the CHY framework, the forward limit operator $\mathcal{F}$ acts on the $(n+2)$-point tree amplitude as follows

$$\mathcal{F} A_{n+2} = \mathcal{F} \left( \int d\mu_{n+2} \mathcal{I}^L(\{k,\epsilon, z\}) \mathcal{I}^R(\{k, \tilde{\epsilon}, z\}) \right)$$

where the measure $d\mu_{n+2}$ is generated from $d\mu_n$ by turning the scattering equations in (2.15) to those in (2.16). Thus the 1-loop CHY integrand is determined by

$$\mathcal{I}_o^L(\{k, \epsilon, z\}) = \mathcal{F} \mathcal{I}^L(\{k, \epsilon, z\}), \quad \mathcal{I}_o^R(\{k, \epsilon, z\}) = \mathcal{F} \mathcal{I}^R(\{k, \epsilon, z\}).$$

Using this statement, the 1-loop CHY integrands for GR, YM and BAS are given in table 2.

| Theory | $\mathcal{I}_o^L(k, \epsilon, z)$ | $\mathcal{I}_o^R(k, \tilde{\epsilon}, z)$ |
|--------|-----------------|-----------------|
| GR     | $\mathcal{F} \text{Pf}^f \Psi$ | $\mathcal{F} \text{Pf}^f \Psi$ |
| YM     | $\text{PT}_o(\sigma_1, \cdots, \sigma_n)$ | $\mathcal{F} \text{Pf}^f \Psi$ |
| BAS    | $\text{PT}_o(\sigma_1, \cdots, \sigma_n)$ | $\text{PT}_o(\sigma'_1, \cdots, \sigma'_n)$ |

Table 2. 1-loop CHY integrands.
The 1-loop CHY formula in (2.21) suffer from the divergence in the forward limit. It was observed in [22] that the solutions of 1-loop scattering equations separate into three sectors which are called regular, singular I and singular II, according to the behavior of punctures \( z_\pm \) in the limit \( k_+ + k_- \to 0 \). In this paper, we will bypass this subtle and crucial point by employing the conclusion in [23], which can be summarized as follows: as long as the CHY integrand is homogeneous in \( \ell^\mu \), the singular solutions contribute to the scaleless integrals which vanish under the dimensional regularization. The homogeneity is manifest for the Parke-Taylor factor. On the other hand, for \( \mathcal{F} \mathcal{Pf} \Psi \), the only place that can violate the homogeneity in \( \ell^\mu \) is the diagonal elements in the matrix \( C \), since the deleted rows and columns are chosen to be \( k_+ \) and \( k_- \). For singular solutions we have \( z_+ = z_- \), then it is direct to observe that the dependence on \( \ell^\mu \) exactly cancel away, left with a homogeneous CHY integrand. The CHY integrands for BI, NLSM, SG, EM and DBI, which will be considered in latter sections, are also homogeneous in \( \ell^\mu \), as can be verified straightforwardly. This observation allows us to ignore the problem of singular solutions.

2.3 Differential operators at tree level

The differential operators introduced by Cheung, Shen and Wen transmute tree amplitudes of one theory to those of other theories [10–12]. Three kinds of basic operators are defined as follows:

- (1) Trace operator:
  \[
  \mathcal{T}^\epsilon[\ell, \ell'] \equiv \partial_{\ell_\epsilon} \cdot \ell'_{\epsilon'},
  \tag{2.26}
  \]
  where \( \epsilon_i \) is the polarization vector of \( i \)th external leg. The up index \( \epsilon \) means the operators are defined through polarization vectors in \( \{\epsilon_i\} \).

- (2) Insertion operator:
  \[
  \mathcal{I}^\epsilon_{ikj} \equiv \partial_{k_i} \ell_i - \partial_{k_j} \ell_j,
  \tag{2.27}
  \]
  where \( k_i \) denotes the momentum of the \( i \)th external leg. When applying to physical amplitudes, the insertion operator \( \mathcal{T}^\epsilon_{ik(i+1)} \) inserts the external leg \( k \) between external legs \( i \) and \( (i+1) \) in the color-ordering \( \cdots, i, i+1, \cdots \). For general \( \mathcal{I}^\epsilon_{ikj} \) with \( i < j \), one can use the definition (2.27) to decompose \( \mathcal{I}^\epsilon_{ikj} \) as
  \[
  \mathcal{I}^\epsilon_{ikj} = \mathcal{I}^\epsilon_{ik(i+1)} + \mathcal{I}^\epsilon_{(i+1)k(i+2)} + \cdots + \mathcal{I}^\epsilon_{(j-1)kj}.
  \tag{2.28}
  \]
  In the above expression, each \( \mathcal{I}^\epsilon_{ak(a+1)} \) on the r.h.s. can be interpreted as inserting the leg \( k \) between \( a \) and \( (a+1) \). Consequently, the effect of \( \mathcal{I}^\epsilon_{ikj} \) can be understood as inserting \( k \) between \( i \) and \( j \) in the color-ordering \( \cdots, i, \cdots, j, \cdots \), and summing over all possible positions together.

- (3) Longitudinal operator:
  \[
  \mathcal{L}^\epsilon_i \equiv \sum_{j \neq i} (k_i \cdot k_j) \partial_{\ell_\epsilon} \ell_i \cdot \ell_j, \quad \mathcal{L}^\epsilon_{ij} \equiv -(k_i \cdot k_j) \partial_{\ell_\epsilon} \ell_i \cdot \ell_j.
  \tag{2.29}
  \]

- 9 -
By using products of these three kinds of basic operators, one can transmute amplitudes of one theory into those of other theories. Three combinatory operators which are products of basic operators are defined as follows:

- (1) For a length-$m$ ordered set $\sigma_m = \{\sigma_1, \cdots, \sigma_m\}$ of external particles, the operator $T^r[\sigma_m]$ is given as

$$T^r[\sigma_m] \equiv \left( \prod_{i=2}^{m-1} T^r_{\sigma_i\sigma_{i+1}} \right) T^r[\sigma_1, \sigma_m].$$

It fixes $\sigma_1$ and $\sigma_m$ at two ends of the color-ordering via the operator $T^r[\sigma_1, \sigma_m]$, and inserts other elements between them by insertion operators. The operator $T^r[\sigma_m]$ is also called the trace operator since it generates the color-ordering $\sigma_1, \sigma_2, \cdots, \sigma_m$. The interpretation of insertions operators indicates that $T^r[\sigma_m]$ has various equivalent formulae, for example

$$T^r[\sigma_m] = \left( \prod_{i=m-1}^{2} T^r_{\sigma_{i-1}\sigma_i} \right) T^r[\sigma_1, \sigma_m],$$

and so on. The second example provided above shows that it is not necessary to choose the first operator to be $T^r[\sigma_1, \sigma_m]$. In other words, two reference legs in the color ordering can be chosen arbitrary.

- (2) For $n$-point amplitudes, the operator $L^c$ is defined as

$$L^c \equiv \prod_i L^c_i, \quad \bar{L}^c \equiv \sum_{\rho \in \text{pair}} \prod_{i,j} L^c_{ij}.$$  

Two definitions $L^c$ and $\bar{L}^c$ are not equivalent to each other at the algebraic level. However, when acting on proper on-shell physical amplitudes, two combinations $L^c \cdot T^r[a,b]$ and $\bar{L}^c \cdot T^r[a,b]$, with subscripts of $L^c_i$ and $L^c_{ij}$ run through all nodes in $\{1, 2, \cdots, n\} \setminus \{a, b\}$, give the same effect which can be interpreted physically.

- (3) For a length-$2m$ set $I$, the operator $T^r_N_{2m}$ is defined as

$$T^r_N_{2m} \equiv \sum_{\rho \in \text{pair}} \prod_{i_k,j_k \in \rho} \delta l_{ik} l_{jk} T^r[i_k, j_k],$$

where $\delta l_{ik} l_{jk}$ forbids the interaction between particles with different flavors. For the special case $2m$ particles do not carry any flavor, the operator $T^r_N_{2m}$ is defined by removing $\delta l_{ik} l_{jk}$,

$$T^r_N_{2m} \equiv \sum_{\rho \in \text{pair}} \prod_{i_k,j_k \in \rho} T^r[i_k, j_k].$$
The explanation for the notation \( \sum_{\rho \in \text{pair}} \prod_{i_k, j_k \in \rho} \) is in order. Let \( \Gamma \) be the set of all partitions of the set \( \{1, 2, \cdots, 2m\} \) into pairs without regard to the order. An element in \( \Gamma \) can be written as

\[
\rho = \{(i_1, j_1), (i_2, j_2), \cdots, (i_m, j_m)\},
\]

with conditions \( i_1 < i_2 < \cdots < i_m \) and \( i_t < j_t, \forall t \). Then, \( \prod_{i_k, j_k \in \rho} \) stands for the product of \( T^\tau_{[i_k, j_k]} \) for all pairs \( (i_k, j_k) \) in \( \rho \), and \( \sum_{\rho \in \text{pair}} \) denotes the summation over all partitions.

The combinatorial operators exhibited above unify tree amplitudes of a wide range of theories together, by translating the GR amplitudes into amplitudes of other theories, formally expressed as

\[
A = O^\tau O^\sim A^\sim_{GR}.
\]

Operators \( O^\tau \) and \( O^\sim \) for different theories, which will be used in this paper, are listed in table 3. In this table, all amplitudes include \( n \) external particles. The symbol \( \mathbb{I} \) stands for the identical operator. Notations \( H_a, P_a, G_a \) and \( S_a \) denote sets of gravitons, photons, gluons and scalars respectively, where the subscript denotes the length of the set. A bold number or letter stands for a set, and \( ^\sim \) denotes that the set is ordered. We use \( A^\sim_{SYMS}(\sigma_m; G_{n-m} | \sigma_n) \) as the example to explain notations \( |, \) and \( : \). The additional color ordering among all external particles is presented at the r.h.s. of the notation \( |, \) such as \( \sigma_n \) among all scalars and gluons in the example. Notation \( : \) is used to separate different sets of external particles, particles on the l.h.s. of \( : \) carry lower spin. In our example, the l.h.s. of \( : \) is the set of scalars while the r.h.s. is the set of gluons. The up index of \( A \) denotes the polarization vectors of external particles. In the cases amplitudes include external gravitons, the rule is: the previous polarization vectors are carried by all particles, while the later ones are only
carried by gravitons. For instance, in the notation $A_{\text{EMI}}^{\varepsilon}(P_{2m}; H_{n-2m})$, $\epsilon_i$ are carried by both photons and gravitons, while $\tilde{\epsilon}_i$ are only carried by gravitons.

In table 3, two sectors of operators labeled by polarization vectors $\epsilon$ and $\tilde{\epsilon}$ are exchangeable. As an example, YM amplitudes carry the polarization vectors $\Psi$ and $\tilde{\Psi}$ to the desired object $\mathcal{PT}[+; \sigma_1, \cdots, \sigma_n, -]$ cyclicly, the BAS Feynman integrand can be generated from the YM Feynman integrand, and the YM Feynman integrand can be generated from the GR Feynman integrand, as can be seen in subsection 3.4.

Thus, the full unified web for tree amplitudes of different theories is involved in table 3.

3 From GR to YM and BAS

In this section, we discuss the differential operator which links the 1-loop Feynman integrands of GR, YM and BAS together. Based on the structure of CHY integrands of these theories in table 2, it is sufficient to find the operator which transmutates the building block $\mathcal{F}\mathcal{Pf}'\Psi$ to the 1-loop Parke-Taylor factor $\mathcal{PT}(\mp; \sigma_1, \cdots, \sigma_n, -)$, then sum over these operators cyclicly to get $\mathcal{PT}_o(\sigma_1, \cdots, \sigma_n)$. In subsection 3.1, we construct the operator $T_o^\epsilon[+; \sigma_1, \cdots, \sigma_n, -]$ satisfies

$$T_o^\epsilon[+; \sigma_1, \cdots, \sigma_n, -] \mathcal{F}\mathcal{Pf}'\Psi = \mathcal{F}T^\epsilon[+; \sigma_1, \cdots, \sigma_n, -] \mathcal{Pf}'\Psi,$$

by general consideration, without respecting to the formula of obtained object at each step. Then, in subsection 3.2, we verify that the operator $T_o^\epsilon[+; \sigma_1, \cdots, \sigma_n, -]$ does transmute $\mathcal{F}\mathcal{Pf}'\Psi$ to the desired object $\mathcal{PT}(\mp; \sigma_1, \cdots, \sigma_n, -)$. The physical interpretation of the insertion operators indicates the freedom of choosing the formula of $T_o^\epsilon[+; \sigma_1, \cdots, \sigma_n, -]$, this issue will be discussed in subsection 3.3. By applying the operator $T_o^\epsilon[+; \sigma_1, \cdots, \sigma_n, -]$ defined as summing over $T_o^\epsilon[+; \sigma_1, \cdots, \sigma_n, -]$ cyclicly, the BAS Feynman integrand can be generated from the YM Feynman integrand, and the YM Feynman integrand can be generated from the GR Feynman integrand, as can be seen in subsection 3.4.

3.1 Constructing operator

Let us try to seek the operator which links the 1-loop GR, YM and BAS Feynman integrands together. As pointed out before, transmuting these integrands is equivalent to transmuting $\mathcal{F}\mathcal{Pf}'\Psi$ to the 1-loop Parke-Taylor factor $\mathcal{PT}_o(\sigma_1, \cdots, \sigma_n)$. Since $\mathcal{PT}_o(\sigma_1, \cdots, \sigma_n)$ can be expanded as

$$\mathcal{PT}_o(\sigma_1, \cdots, \sigma_n) = \sum_{i \in \{1, \cdots, n\}} \mathcal{PT}(\mp; \sigma_i, \cdots, \sigma_{i-1}, -),$$

for example, from relations

$$\mathcal{A}_{\text{BI}}(P_n) = \mathcal{L}^\varepsilon T^\varepsilon[a, b]\mathcal{A}_{\text{GR}}^{\varepsilon}(H_n),$$

$$\mathcal{A}_{\text{NLSM}}(\sigma_n) = T^\varepsilon[\sigma_n]\left(\mathcal{L}^\varepsilon T^\varepsilon[a, b]\mathcal{A}_{\text{GR}}^{\varepsilon}(H_n)\right),$$

one can get

$$\mathcal{A}_{\text{NLSM}}(\sigma_n) = T^\varepsilon[\sigma_n]\mathcal{A}_{\text{BI}}(P_n).$$

(3.1)
As the analog, our first step should be choosing two reference legs in the color ordering $+$, $\sigma_1, \ldots, \sigma_n, -$ which transmutes $F \mathcal{P} f \Psi$ to the tree Parke-Taylor factor $PT(\mathcal{P} f \Psi)$, then sum over the operators $T_\sigma[+, \sigma_1, \ldots, \sigma_{n-1}, -]$ cyclically.

Before starting, we point out that if the action of the differential operator at tree level is commutative with taking forward limit, one can conclude that the desired operator at 1-loop level is totally the same, since the 1-loop integrand is obtained via the forward limit. Unfortunately, as can be seen soon, such commutativity is not satisfied. Thus, the differential operator which links the tree level GR, YM and BAS amplitudes together cannot be applied directly to the 1-loop case.

Although the tree level operator does not make sense at the 1-loop level directly, we still hope the effects of desired 1-loop operator are paralleled to those at tree level, at each step. More explicitly, we expect the operator $T_\sigma[+, \sigma_1, \ldots, \sigma_m, -]$ to satisfy

$$T_\sigma[+, \sigma_1, \ldots, \sigma_m, -] F \mathcal{P} f \Psi = F T_\sigma[+, \sigma_1, \ldots, \sigma_m, -] \mathcal{P} f \Psi,$$

(3.3)

for each $m$ with $0 \leq m \leq n$, where the tree level operator $T^\prime(\mathcal{P} f \Psi)$ is defined in (2.30). At the tree level, the first step of applying $T^\prime[\mathcal{P} f \Psi]$ is to perform the operator $T_\sigma[\mathcal{P} f \Psi] \equiv \partial_{\mathcal{P} f \Psi}$. This manipulation has two effects, one is reducing the spins of external particles $a$ and $b$ by 1, another one is creating the color ordering $\vec{a}, \vec{b}$, where the legs $a$ and $b$ play the role of reference legs for inserting more legs into the color ordering. As the analog, our first step should be choosing two reference legs in the color ordering $\mathcal{P} f \Psi$, and reduce the corresponding spins simultaneously. Since the 1-loop Parke-Taylor factor can be expanded as in (3.2), it is nature to choose $+$ and $-$ as reference legs.\footnote{After taking the forward limit, $+$ and $-$ are no longer external legs of the amplitude. But when discussing the Parke-Taylor factor $PT(\mathcal{P} f \Psi)$, we still call them “leg”.

5} However, when taking the forward limit, the polarization vectors of tree level external legs $+$ and $-$ are summed as

$$\sum_r (\epsilon^r_+)\mu (\epsilon^-_\nu)(A_{n+2}^{\text{tree}})^{\mu\nu} = \sum_r (\epsilon^r_+)\mu (\epsilon^-_+)^{\mu\nu},$$

(3.4)

thus neither $\epsilon_+$ nor $\epsilon_-$ will appear in the 1-loop integrand. To handle this, we observe that

$$\sum_r (\epsilon^r_+) = D - 2,$$

and dividing $\epsilon_+ \cdot \epsilon_-$ at tree level is equivalent to dividing $(D - 2)$ at 1-loop level, due to the summation (3.4). Here we think the Lorentz vectors as follows, the momenta in $\{k_1, \ldots, k_n, \ell\}$ and polarization vectors in $\{\epsilon_1, \ldots, \epsilon_n\}$ lie in the $d$ dimensional space where $d$ is regarded as a constant, while the polarization vectors $\epsilon_+$ and $\epsilon_-$ are in the $D$ dimensional space where $D$ is regarded as a variable. We can set $D = d$ finally to obtain a physically acceptable object. The reason for this treatment will be seen soon.

The above observation is not enough, due to another effect of $\partial_{\epsilon_+ \epsilon_-}$ at tree level. Since each polarization vector appears once and only once in each term of the amplitude, the operator $\partial_{\epsilon_+ \epsilon_-}$ turns all $\epsilon_+ \cdot V$ and $\epsilon_- \cdot V$ except $\epsilon_1 \cdot \epsilon_2$ to 0 at tree level. Here $V$ denotes Lorentz vectors including both polarization vectors and external momenta. Thus, to realize all effects of the operator $\partial_{\epsilon_+ \epsilon_-}$, the associated manipulation at the 1-loop level can be chosen as

$$\mathcal{D} F \mathcal{P} f \Psi = \frac{\partial}{\partial D} \left( F \mathcal{P} f \Psi \right).$$

(3.5)
The reason we regard $D$ as a variable is to make the operator $\partial_D$ to be well defined. The operator $\mathcal{D}$ defined above selects the terms contain the factor $(D-2)$ in $\mathcal{F} \text{Pf}^\ell \Psi$, and annihilates all the other terms. After applying this operator, the obtained object does not depend on $\epsilon_+$ and $\epsilon_-$ anymore, all remaining Lorentz vectors in $\mathcal{D} \mathcal{F} \text{Pf}^\ell \Psi$ are $d$ dimensional, as they should be. Thus, we now have

$$\mathcal{D} \mathcal{F} \text{Pf}^\ell \Psi = \mathcal{F} T^\epsilon [\underline{\epsilon^+,\underline{\epsilon^-}}] \text{Pf}^\ell \Psi,$$  \hspace{1cm} (3.6)

at the first step.

With two reference legs $+$ and $-$ on hand, now we need to insert a leg between them, and decrease the spin of the corresponding particle by 1. Suppose we insert the leg $n$ at this step, at tree level, the insertion is realized by applying the operator

$$T_{^+n^-}^\epsilon \equiv \partial_{\epsilon_n,k_+} - \partial_{\epsilon_n,k_-}.$$  \hspace{1cm} (3.7)

At 1-loop level, if we apply the operator $T_{^+n^-}^\epsilon$ directly, we will encounter the ambiguity that $\partial_{\epsilon_n,k_+}$ acts not only on $\epsilon_n \cdot k_+$, but also on $\epsilon_n \cdot k_-$, and similar does $\partial_{\epsilon_n,k_-}$, since $k_+ = -k_- = \ell$. To handle this, we observe that in the limit $k_+ \to \pm \ell$ we have

$$\partial_{\epsilon_n,k_+} (\epsilon_n \cdot k_-) = -\partial_{\epsilon_n,k_-} (\epsilon_n \cdot k_-),$$
$$\partial_{\epsilon_n,k_+} (\epsilon_n \cdot k_+) = -\partial_{\epsilon_n,k_-} (\epsilon_n \cdot k_+).$$  \hspace{1cm} (3.8)

It means the operator $-\partial_{\epsilon_n,k_-}$ is equivalent to the operator $\partial_{\epsilon_n,k_+}$. Thus, it is natural to choose

$$T_{^0^+n^-}^\epsilon \equiv \partial_{\epsilon_n,\ell}.$$  \hspace{1cm} (3.9)

Under this choice, all the effects arise from $-\partial_{\epsilon_n,k_-} (\epsilon_n \cdot k_-)$ at tree level are replaced by those from $\partial_{\epsilon_n,k_+} (\epsilon_n \cdot k_-)$, and the first line in (3.8) ensures that the resulting object will not be alternated. Consequently, at the second step, we found

$$T_{^0^+n^-}^\epsilon \mathcal{D} \mathcal{F} \text{Pf}^\ell \Psi = \mathcal{F} T_{^+n^-}^\epsilon [\underline{\epsilon^+,\underline{\epsilon^-}}] \text{Pf}^\ell \Psi.$$  \hspace{1cm} (3.10)

The next step is to insert another leg, for example the leg $(n-1)$, between $+$ and $n$, and decrease the spin of the external particle $(n-1)$. At tree level, it is realized via the insertion operator

$$T_{^+(n-1)n}^\epsilon \equiv \partial_{\epsilon_{n-1},k_+} - \partial_{\epsilon_{n-1},k_n}.$$  \hspace{1cm} (3.11)

Here we also encounter the ambiguity arise from the fact $k_+ = -k_- = \ell$. In practice, this obstacle can be bypassed by employing the momentum conservation law. Using the momentum conservation, one can always remove one of external momenta in the formula of the tree amplitude. Suppose we remove $k_-$ before taking the forward limit, then $k_-$ will not appear in the numerator of the Feynman integrand. Then, we can safely define the insertion operator at 1-loop level as

$$T_{^0^+(n-1)n}^\epsilon \equiv \partial_{\epsilon_{n-1},\ell} - \partial_{\epsilon_{n-1},k_n}.$$  \hspace{1cm} (3.12)

Thus, we now arrive at

$$T_{^0^+(n-1)n}^\epsilon T_{^0^+n^-}^\epsilon \mathcal{D} \mathcal{F} \text{Pf}^\ell \Psi = \mathcal{F} T_{^+(n-1)n}^\epsilon T_{^+n^-}^\epsilon [\underline{\epsilon^+,\underline{\epsilon^-}}] \text{Pf}^\ell \Psi.$$  \hspace{1cm} (3.13)
The above insertion procedure can be performed recursively to insert other legs between 1 and \((n - 1)\), until the full color ordering is obtained.

Combining all the manipulations together, the desired operator which satisfies the relation \((3.3)\) is conjectured as follows

\[
T^\epsilon_o[\ +, \sigma_1, \ldots, \sigma_m, -] \equiv \left( \prod_{i=1}^{m-1} T^\epsilon_{o_i+\sigma_i(\sigma_{i+1})} \right) T^\epsilon_{o_m+\sigma_m} D , \tag{3.14}
\]

where the operators \(D, T^\epsilon_{o_i+\sigma_i} \) and \(T^\epsilon_{o_i+\sigma_i(\sigma_{i+1})} \) are defined in \((3.5), (3.9)\) and \((3.12)\), respectively. This operator is constructed by imposing the requirement \((3.3)\) at each step, thus its physical effect is strictly paralleled to the effect of the tree level operator \(T^\epsilon[\ +, \sigma_1, \ldots, \sigma_m, -] \). In the next subsection, we will verify that the operator \(T^\epsilon_o[\ +, \sigma_1, \ldots, \sigma_n, -] \) transmute the ingredient \(\mathcal{F} \Phi \tau \Psi \) to the Parke-Taylor factor \(PT(\ +, \sigma_1, \ldots, \sigma_n, -) \), as implied by our argument in the current subsection.

### 3.2 Transmuting \(\mathcal{F} \Phi \tau \Psi \)

Now we apply the conjectured operator \(T^\epsilon_o[\ +, \sigma_1, \ldots, \sigma_n, -] \) to the 1-loop ingredient \(\mathcal{F} \Phi \tau \Psi \), and verify that

\[
T^\epsilon_o[\ +, \sigma_1, \ldots, \sigma_n, -] \mathcal{F} \Phi \tau \Psi = PT(\ +, \sigma_1, \ldots, \sigma_n, -) , \tag{3.15}
\]

up to an overall sign. Without lose of generality, we take \(\sigma_i = i\) for simplicity in this subsection.

The first step is to apply the operator \(D \) to \(\mathcal{F} \Phi \tau \Psi \). As analysed in the previous subsection, when applying to \(\sum_r (\epsilon^r_+)\epsilon(\epsilon^-_r) \omega(A^{\text{tree}}_{n+2})_{\mu\nu} \), the operator \(D \) turns \(\sum_r \epsilon^r_+ \cdot \epsilon^-_r \) to 1, and annihilates all terms do not contain \(\sum_r \epsilon^r_+ \cdot \epsilon^-_r \). Thus, we have

\[
D \mathcal{F} \Phi \tau \Psi = D \left( \sum_r \Phi \tau \Psi^r_\ell \right) = \Phi \tau \tilde{\Psi}_\ell , \tag{3.16}
\]

where the new matrix \(\tilde{\Psi}_\ell \) is obtained from \(\Psi_\ell \) via the replacement

\[
\epsilon_+ \cdot \epsilon^- \rightarrow 1 , \quad \epsilon_+ \cdot V \rightarrow 0 , \quad \epsilon^- \cdot V \rightarrow 0 . \tag{3.17}
\]

Without lose of generality, we assume the rows and columns in the matrix \(\Psi_\ell \) are arranged by the order \(\{1, \ldots, n, +, -\} \),\(^6\) then the matrix \(\tilde{\Psi}_\ell \) becomes

\[
\tilde{\Psi}_\ell = \begin{pmatrix}
A_{(n+2)\times(n+2)} & C_{(n+2)\times n} & 0 \\
-C_{n\times(n+2)}^T & B_{n\times n} & 0 \\
0 & 0 & X_{2\times2}
\end{pmatrix} = \begin{pmatrix}
[\Psi_\ell]_{n,+,-} & 0 \\
0 & [X]_2
\end{pmatrix} , \tag{3.18}
\]

with

\[
[X]_2 = \begin{pmatrix}
\frac{1}{z^+} & 0 \\
0 & \frac{1}{z^-}
\end{pmatrix} . \tag{3.19}
\]

\(^6\)This assumption can be realized by moving lows and columns. Since \((n + i)^{th}\) row and column will be moved simultaneously while moving \(i^{th}\) ones, the possible \(-\) sign will not arise.
Notice that the above derivation is ensured by the observation that $D$ in $\mathcal{F} \text{Pf}^t \Psi$ only arise from $\sum_r \epsilon_r^+ \cdot \epsilon_r^-$. A simple way to see this fact is to use the expanded formula of the reduced Pfaffian proposed by Lam [26], expressed as follows,

$$\text{Pf}^t \Psi = -2^{n-1} \sum_{P \in S_{n+2}} (-1)^p W_I U_J \cdots U_K \frac{z_p}{z_p}, \quad z_p = z_I z_J \cdots z_K. \quad (3.20)$$

Here $I = \{\alpha_i\}$, $J = \{\beta_j\}$, $K = \{\beta_k\}$ are ordered subsets of $\{+, 1, \cdots, n, -\}$, and $z_I = z_{\alpha_1 \alpha_2} \cdots z_{\alpha_n \alpha_1}$, and so does $z_J$, $z_K$. In this formula, Lorentz vectors are included in the objects

$$W_I = \epsilon^n_+ \cdot f_{\alpha_1} \cdots f_{\alpha_m} \cdot \epsilon^n_-, \quad U_J = \text{Tr} \left( f_{\beta_1} \cdots f_{\beta_{m'}} \right), \quad (3.21)$$

where $f_{\mu\nu}$ are field strength tensors defined as $f_{\mu\nu} \equiv k_\mu^a \epsilon_\nu^a - \epsilon_\mu^a k_\nu^a$. After taking $k_1 \to \pm \ell$ and summing over $r$, only $W_I$ with $\{\alpha_i\} = \emptyset$ contributes $(D - 2)$.

The reduced Pfaffian of $\Psi_l$ can be calculated directly as

$$\text{Pf}^t \Psi_l = \text{Pf}^t [\Psi_l]_{n,+,-:n} \text{Pf}[X]_2$$

$$= \frac{-1}{z_+^-} \text{Pf} [\Psi_l]_{n:n} \text{Pf}[X]_2$$

$$= \frac{1}{z_+^- z_-^+} \text{Pf} [\Psi_l]_{n:n}. \quad (3.22)$$

As can be seen, the desired Parke-Taylor factor $PT(\bar{+}, -)$ which indicates the color ordering $\bar{+}, -$ has appeared. Comparing with the effect of applying $T^t(\bar{+}, -)$ to $\text{Pf}^t \Psi$, we see that

$$\mathcal{D} \mathcal{F} \text{Pf}^t \Psi = \mathcal{F} T^t(\bar{+}, -) \text{Pf}^t \Psi,$$  

as argued in the previous subsection.

The next step is to perform the operator $T^{(\epsilon)}_{\alpha_i n^-} \equiv \partial_{\epsilon \alpha_i \ell}$. To do this, we observe that $\epsilon_n \cdot \ell$ only occurs in $C_{nn}$ in the matrix $[\Psi_l]_{n:n}$. Using the definition of $C_{nn}$, we get

$$T^{(\epsilon)}_{\alpha_i n^-} C_{nn} = -\frac{1}{z_+^-} + \frac{1}{z_-^+} = \frac{z_+^-}{z_+^- z_-^+}. \quad (3.24)$$

Then we need to reorganize the remaining part in $\text{Pf}[\Psi_l]_{n:n}$. Using the definition of Pfaffian in (2.12), we can expand $\text{Pf}[\Psi_l]_{n:n}$ as

$$\text{Pf}[\Psi_l]_{n:n} = \sum_{\alpha \in \Pi} \text{sgn}(\sigma_\alpha) [\Psi_l]_{a_1 b_1} [\Psi_l]_{a_2 b_2} \cdots [\Psi_l]_{a_n b_n}, \quad (3.25)$$

where the element $[\Psi_l]_{a_i b_i}$ is the element at the $a_i$th row and $b_i$th column in the matrix $[\Psi_l]_{n:n}$. The operator $\partial_{\epsilon \alpha_i \ell}$ selects terms containing the element $[\Psi_l]_{n:2n}$, since $C_{nn}$ is located at the $n$th row and $2n$th column. The remaining part after removing $[\Psi_l]_{n:2n}$ corresponds to a partition of the set $\{1, 2, \cdots, 2n\} \setminus \{n, 2n\}$, which has the length $2(n - 1)$. Such a term appears in $\text{Pf}[\Psi_l]_{n-1:n-1}$, weighted by a new signature $\text{sgn}(\sigma_\alpha)$, where the new matrix $[\Psi_l]_{n-1:n-1}$ is obtained from the original one $[\Psi_l]_{n:n}$ by deleting $n$th and $2n$th rows and columns, and $\text{sgn}(\sigma_\alpha)$ corresponds to the partition of the length-$2(n - 1)$ set. By comparing
these two special partitions, where one belongs to the original matrix and one belongs to the new one,

\[ \alpha = \{(a_1, b_1), (a_2, b_2), \ldots, (n, 2n), \ldots, (a_n, b_n)\}, \]

\[ \tilde{\alpha} = \{(a_1, b_1), (a_2, b_2), \ldots, (a_n, b_n)\}, \] (3.26)

one can get \( \text{sgn}(\sigma_\alpha) = (-)^{n-1} \text{sgn}(\sigma_\alpha) \). Consequently, summing over all survived terms gives

\[ T_{0;+n-n}^\ell \mathcal{PF}[\Psi_\ell]_{n:n} = \frac{(-)^{n-1} \text{sgn}(\sigma_\alpha)}{z+n z_n^{-}} \mathcal{PF}[\Psi_\ell]_{n-1:n-1}. \] (3.27)

Combining (3.16), (3.22) and (3.27) together gives

\[ T_{0;+n-n}^\ell \mathcal{D} \mathcal{F} \mathcal{PF}^\ell \Psi = \frac{(-)^{n}}{z+n z_n^{-}} \mathcal{PF}[\Psi_\ell]_{n-1:n-1}. \] (3.28)

We see that the operator \( T_{0;+n-n}^\ell \mathcal{D} \mathcal{F} \mathcal{PF}^\ell \Psi \) transmutes the Parke-Taylor factor \( \mathcal{PT}(+, -) \) to the new one \( \mathcal{PT}(+, n, -) \) which indicates the color ordering \( +, n, - \). At this step we have

\[ T_{0;+n-n}^\ell \mathcal{F} \mathcal{PF}^\ell \Psi = \mathcal{F} \mathcal{T}^\ell[+, n, -] \mathcal{PF}^\ell \Psi, \] (3.29)

which validates our main idea.

Then we need to apply the operator \( T_{0;+n-n}^\ell \mathcal{D} \mathcal{F} \mathcal{PF}^\ell \Psi \) to the new one \( \mathcal{PT}(+, n, -) \) to rewrite the elements \( C_{i i} \) as

\[ C_{ii} = \sum_{j \neq i, -} \frac{(k_j \cdot \epsilon_i) z^{-j}}{z_{j i} z_{i i}^{-}}. \] (3.30)

In the rewritten form, the momenta \( k_- = -\ell \) has been removed. A little algebra yields

\[ T_{0;+n-n}^\ell C_{(n-1)(n-1)} = \frac{z+n}{z+(n-1) z_{n(n-1)}}. \] (3.31)

Using this, together with the discussion about partitions in the previous step, we find

\[ T_{0;+n-n}^\ell \mathcal{PF}[\Psi_\ell]_{n-1:n-1} = \frac{(-)^{n-2} z+n}{z+(n-1) z_{n(n-1)}} \mathcal{PF}[\Psi_\ell]_{n-2:n-2}, \] (3.32)

thus

\[ T_{0;+n-n}^\ell T_{0;+n-n}^\ell \mathcal{F} \mathcal{PF}^\ell \Psi = \frac{(-)^{n}(-)^{n-1}}{z+(n-1) z_{n(n-1)} z_{n-} z_{-+}} \mathcal{PF}[\Psi_\ell]_{n-2:n-2}. \] (3.33)

Here the matrix \( [\Psi_\ell]_{n-2:n-2} \) is obtained from \( [\Psi_\ell]_{n-1:n-1} \) by deleting \((n-1)^{\text{th}}\) and \(2(n-1)^{\text{th}}\) rows and columns. At this step, the Parke-Taylor factor \( \mathcal{PT}(+, (n-1), n, -) \) has been generated. We again notice that

\[ T_{0;+n-n}^\ell \mathcal{F} \mathcal{PF}^\ell \Psi = \mathcal{F} \mathcal{T}^\ell[+, n-1, n, -] \mathcal{PF}^\ell \Psi. \] (3.34)
The manipulation at this step can be performed recursively, and finally we arrive at
\begin{equation}
T'_0[\mp,1,\cdots,n,-] \mathcal{F} \text{ Pf}' \Psi = (-)^{\frac{n(n+1)}{2}} PT(\mp,1,\cdots,n,-). \tag{3.35}
\end{equation}

Thus, we conclude that the operator \(T'_0[\mp,\sigma_1,\cdots,\sigma_n,-]\) transmutes \(\mathcal{F} \text{ Pf}' \Psi\) to the tree Parke-Taylor factor \(PT(\mp,\sigma_1,\cdots,\sigma_n,-)\), up to an overall sign \((-)^{\frac{n(n+1)}{2}}\). We also verified that the key requirement (3.3) is satisfied at each step.

### 3.3 Freedom of choosing insertion operators

In the previous subsection, the color ordering \(+,1,\cdots,n,−\) is obtained by giving two reference legs \(+\) and \(−\) at the first step, then inserting the leg \(n\) between \(+\) and \(−\), and then inseting \((n-1)\) between \(+\) and \(n\), and so on. It is natural to ask if the insertions can be done in different manners. For example, consider the color ordering \(+,1,2,3,−\). The algorithm in the previous subsection is as follows:

- Create reference legs \(+\) and \(−\);
- Insert 3 between \(+\) and \(−\);
- Insert 2 between \(+\) and 3;
- Insert 1 between \(+\) and 2.

However, it is natural to image other manners such as

- Create reference legs \(+\) and \(−\);
- Insert 2 between \(+\) and \(−\);
- Insert 1 between \(+\) and 2;
- Insert 3 between \(2\) and \(−\).

Let us verify the above alternative manner by rigorous calculation. The definitions of insertion operators \(I'_{\epsilon \circ ;+2−}\) and \(I'_{\epsilon \circ ;+12}\) can be found in (3.9) and (3.12), respectively. As the analog of the tree level insertion operator, we also introduce the operator
\begin{equation}
I'_{\epsilon \circ ;23} \equiv \partial_{\epsilon_3 \cdot k_2} - \partial_{\epsilon_3 \cdot k_2} = \partial_{\epsilon_3 \cdot k_2} + \partial_{\epsilon_3 \cdot \ell}. \tag{3.36}
\end{equation}

When applying \(T'_{0;23-}\) to \(C_{33}\), to avoid the ambiguity that \(\partial_{\epsilon_3 \cdot \ell}\) acts on \(\epsilon_3 \cdot k_+\), one should rewrite \(C_{33}\) as
\begin{equation}
C_{33} = \sum_{j \neq 3,-} \frac{(k_j \cdot \epsilon_3)z_{±j}}{z_3 z_3}. \tag{3.37}
\end{equation}

Then, following the calculation in the previous subsection, we find that the alternative operator, defined by
\begin{equation}
T'_0[\mp,1,2,3,-] \equiv T'_0[\mp,23-] T'_0[\pm,12] T'_0[\pm,2-] D, \tag{3.38}
\end{equation}
transmutes \(\mathcal{F} \text{ Pf}' \Psi\) to the Parke-Taylor factor \(PT(\mp,1,2,3,-)\), as expected.
We have constructed the operator \( T \) where the insertion operators can be separated into 4 classes, defined as follows,

\[
T^{e}_{o;+i} = \partial \epsilon_i \ell, \quad T^{+k}_{o;+j} = \partial \epsilon_k \ell - \partial \epsilon_j k, \\
T^{e}_{o;ij} = \partial \epsilon_i \ell - \partial \epsilon_j \ell, \quad T^{+k}_{o;ijk} = \partial \epsilon_k \ell - \partial \epsilon_j k.
\]

Each \( T^{eabc}_{o} \) can be understood as turning the Parke-Taylor factor \( PT(\cdots, a, b, c, \cdots) \) to \( PT(\cdots, a, c, b, \cdots) \). All \( T^{e}_{o;+i} \) constructed via the above interpretation satisfy our requirement.

### 3.4 Relations among GR, YM and BAS Feynman integrands

We have constructed the operator \( T^{e}_{o;+i} \) which transmutes \( F \Psi \) to \( PT(\cdots, a, c, \cdots) \). Now we introduce the operator \( T^{e}_{oc}[\sigma_1, \cdots, \sigma_n] \) as

\[
T^{e}_{oc}[\sigma_1, \cdots, \sigma_n] = \sum_{i=1}^{n} T^{e}_{o;+i} + \sigma_i - \sigma_{i-1} - \sigma_n.
\]

Clearly, the operator \( T^{e}_{oc}[\sigma_1, \cdots, \sigma_n] \) defined above transmutes \( F \Psi \) to \( PT(\cdots, a, c, \cdots) \).

It is natural to expect that this operator transmutes the 1-loop GR CHY integrand to the 1-loop YM CHY integrand, and transmutes the 1-loop YM CHY integrand to the BAS CHY integrand, due to the structures of 1-loop CHY integrands established in Table 2. Since this operator does not modify the measure of CHY contour integral, it is commutative with the CHY contour integral. Thus, we conclude this operator transmutes the 1-loop GR Feynman integrand to the 1-loop YM Feynman integrand, and transmutes the 1-loop YM Feynman integrand to the BAS Feynman integrand.

To really achieve the goal described above, we require that the polarization vectors \( \epsilon_+ \) and \( \epsilon_- \) are \( D \) dimensional, while the polarization vectors \( \tilde{\epsilon}_+ \) and \( \tilde{\epsilon}_- \) are \( \tilde{D} \) dimensional.

Now we introduce

\[
\mathcal{D}T^{e}_{ocGR} = \frac{\partial}{\partial \mathcal{D}} \left( T^{e}_{ocGR} \right), \quad \tilde{\mathcal{D}}T^{e}_{ocGR} = \frac{\partial}{\partial \tilde{\mathcal{D}}} \left( T^{e}_{ocGR} \right).
\]

Here \( \mathcal{D} \) and \( \tilde{\mathcal{D}} \) are two different variables, thus the operator \( \mathcal{D} \) will not affect \( T^{e}_{ocGR} \), while the operator \( \tilde{\mathcal{D}} \) will not affect \( \frac{\partial}{\partial \mathcal{D}} \). Then we define two operators

\[
T^{e}_{o;+i} \equiv \left( \prod_{i=1}^{n} T^{e}_{o;+i} + \sigma_i - \sigma_{i-1} - \sigma_n \right) , \\
T^{e}_{o;ij} \equiv \left( \prod_{i=1}^{n} T^{e}_{o;+i} + \sigma_i - \sigma_{i-1} - \sigma_n \right) ,
\]

where the insertion operators \( T^{eabc}_{o;abc} \) and \( T^{eabc}_{o;abc} \) are defined via polarization vectors in \( \{\epsilon_i\} \) and \( \{\tilde{\epsilon}_i\} \), respectively. Applying these two operators, we have

\[
T^{e}_{o;+i} \left( T^{e}_{ocGR} T^{e}_{ocGR} \right) = PT(\cdots, a, c, \cdots) T^{e}_{ocGR}, \\
T^{e}_{o;ij} \left( T^{e}_{ocGR} T^{e}_{ocGR} \right) = T^{e}_{ocGR} PT(\cdots, a, c, \cdots),
\]

The goal described above is achieved.
Applying the above operators without any ambiguity. Then, we define
\[
\mathcal{T}_C[\sigma_1, \ldots, \sigma_n] = \sum_{i=1}^{n} \mathcal{T}_0[+; \sigma_i, \ldots, \sigma_{i-1}; -], \\
\tilde{\mathcal{T}}_C[\sigma_1', \ldots, \sigma_n'] = \sum_{i=1}^{n} \tilde{\mathcal{T}}_0[+; \sigma_i', \ldots, \sigma_{i-1}'; -].
\] (3.44)

Applying the above operators \(\mathcal{T}_C[\sigma_1, \ldots, \sigma_n]\) and \(\tilde{\mathcal{T}}_C[\sigma_1', \ldots, \sigma_n']\) to \((\tilde{I}_0^{L} \tilde{I}_0^{H})\), and using the commutativity between the operators and the CHY integral, we arrive at the following relations
\[
\begin{align*}
I^{\epsilon}_{YM}(\sigma_1, \ldots, \sigma_n) &= \mathcal{T}^\epsilon_C[\sigma_1', \ldots, \sigma_n'] I^{\epsilon}_{GR}(H_n), \\
I^{\epsilon}_{YM}(\sigma_1, \ldots, \sigma_n) &= \mathcal{T}^\epsilon_C[\sigma_1, \ldots, \sigma_n] I^{\epsilon}_{GR}(H_n), \\
I_{BAS}(\sigma_1, \ldots, \sigma_n|\sigma_1', \ldots, \sigma_n') &= \mathcal{T}^\epsilon_C[\sigma_1, \ldots, \sigma_n] I_{YM}(\sigma_1', \ldots, \sigma_n') \\
&= \mathcal{T}^\epsilon_C[\sigma_1', \ldots, \sigma_n'] I_{YM}(\sigma_1, \ldots, \sigma_n) \\
&= \mathcal{T}^\epsilon_C[\sigma_1, \ldots, \sigma_n] \tilde{\mathcal{T}}^\epsilon_C[\sigma_1', \ldots, \sigma_n'] I^{\epsilon}_{GR}(H_n). 
\end{align*}
\] (3.45)

From these relations, we see that by applying operators \(\mathcal{T}^\epsilon_C[\sigma_1, \ldots, \sigma_n]\) and \(\tilde{\mathcal{T}}^\epsilon_C[\sigma_1', \ldots, \sigma_n']\), the 1-loop YM Feynman integrand can be generated from the GR Feynman integrand, and the BAS Feynman integrand can be generated from the YM Feynman integrand.

Some remarks are in order. When applying to \(I^{\epsilon}_{GR}(H_n)\), two operators \(\mathcal{T}^\epsilon_C[\sigma_1', \ldots, \sigma_n']\) and \(\tilde{\mathcal{T}}^\epsilon_C[\sigma_1, \ldots, \sigma_n]\) work well as long as \(I^{\epsilon}_{GR}(H_n)\) includes two parameters \(D\) and \(\tilde{D}\). Of course we have \(D = \tilde{D} = d\), but we need to separate \(d\) into two sectors and denote them by \(D\) and \(\tilde{D}\) respectively. This requirement is realized naturally via the forward limit method, since \(D\) and \(\tilde{D}\) arise from two distinguished sectors of polarization vectors. Thus, to apply the operators considered above, one needs to denote \(d - 2 = \sum r e_\alpha \cdot e_\alpha\) as \((D - 2)\) and denote \(d - 2 = \sum c_\lambda \cdot c_\lambda\) as \((\tilde{D} - 2)\) when using the forward limit method to write down the 1-loop Feynman integrand.

Before ending this subsection, we emphasize that the operators \(\mathcal{T}^\epsilon_C[\sigma_1', \ldots, \sigma_n']\) and \(\tilde{\mathcal{T}}^\epsilon_C[\sigma_1, \ldots, \sigma_n]\) are not commutative with the 1-loop Feynman integral, since they affect on Lorentz invariants \(\epsilon_i \cdot l\) and \(\vec{c}_j \cdot l\) which depend on the loop momentum. Thus, the relations discussed above only hold at the Feynman integrands level, i.e., they are not satisfied at the 1-loop amplitudes level.

4 Other theories

In the previous section, we constructed the operator \(\mathcal{T}^\epsilon_C[\sigma_1, \ldots, \sigma_n]\) which links the 1-loop Feynman integrands of GR, YM and BAS together. These relations are inherited from the relations at tree level, and the basic idea is to seek the operator \(\mathcal{O}_\epsilon\) satisfying \(\mathcal{O}_\epsilon \mathcal{F} \mathcal{P}^I \Psi = \mathcal{F} \mathcal{O}' \mathcal{P}^I \Psi\). At tree level, the unified web includes a large variety of theories, as can be seen in table 3. Thus, the aim of this section is to apply the same idea to other theories included in table 3, to construct more 1-loop level operators which generates the 1-loop Feynman integrands of other theories.
The CHY integrands for theories under consideration in this section have not been given explicitly in literatures, but can be obtained easily via the forward limit method. For the 1-loop CHY formula for a new theory, one may encounter the problem of singular solutions of scattering equations. Fortunately, all CHY integrands which will be considered in this section are homogeneous in $\ell^n$, as can be verified directly. As discussed in subsection 2.2, using the conclusion in [23], we can claim that all singular solutions contribute to scaleless integrals which vanish under the dimensional regularization, and ignore them.

In subsection 4.1, we show that the operator $T_{0c}^c[\sigma_1, \cdots, \sigma_m]$ with $m < n$ transmutes the 1-loop $n$-point GR Feynman integrand to the single trace 1-loop $n$-point EYM Feynman integrand, with a gluon running in the loop, and also transmutes the 1-loop $n$-point YM Feynman integrand to the single trace 1-loop $n$-point BAS Feynman integrand, with a scalar running in the loop. We call them the special Feynman integrands of single trace EYM and single trace YMS, and denote them as ssEYM and ssYMS, respectively. In subsection 4.2, we discuss the operator which transmutes the 1-loop GR Feynman integrand to the BI and SG Feynman integrands, and also transmutes the 1-loop YM Feynman integrand to the NLSM integrand. In subsection 4.3, we consider the operator which transmutes 1-loop GR Feynman integrand to the EM Feynman integrand, and transmutes the 1-loop BI Feynman integrand to the DBI Feynman integrand. In this subsection, new situation arises from the fact the virtual particle running in the loop is not unique, which means the operator $F$ is not unique, thus one can not expect that the full 1-loop single trace EYM Feynman integrand with fixed external legs and color ordering can be obtained through the above manipulation. The reason is, for the EYM theory, the virtual particle running in the loop can be either gluon or graviton, as shown in figure 1, but the operator $D$ indicates that the forward limit is took for two external gluons thus the diagrams with only a graviton running in the loop are excluded. Now we argue that after performing the operator $D$, the only candidate for

4.1 ssEYM and ssYMS

In the previous section, we constructed the operator $T_0^c[\sigma_1, \cdots, \sigma_m, -]$ satisfying the relation (3.3). We also proved that the operator $T_0^c[\sigma_1, \cdots, \sigma_m, -]$ transmutes the object $F \cdot PT(\Psi)$ to the Parke-Taylor factor $PT(\Psi)$, which contributes to the 1-loop CHY integrands of YM and BAS. It is natural to ask the physical interpretation of the resulting object after performing $T_0^c[\sigma_1, \cdots, \sigma_m, -]$, with $0 \leq m < n$.

We begin the discussion of this subject by applying $T_0^c[\sigma_1, \cdots, \sigma_m, -]$ to the 1-loop GR Feynman integrand. At tree level, the corresponding operator $T^c[\sigma_1, \cdots, \sigma_m, -]$ transmutes the GR amplitude to the single trace EYM one as follows

$$T^c[\sigma_1, \cdots, \sigma_m, -]A_{GR}^c(H_{n+2}) = A_{EYM}^c(\sigma_1, \cdots, \sigma_m, -; H_{n-m}). \quad (4.1)$$

Using the relation (3.3), we conclude that the object $T_0^c[\sigma_1, \cdots, \sigma_m, -]F A_{GR}^c(H_{n+2})$ can be understood as the forward limit $F A_{EYM}^c(\sigma_1, \cdots, \sigma_m, -; H_{n-m})$, thus contributes to the 1-loop EYM Feynman integrand.

However, one can not expect that the full 1-loop single trace EYM Feynman integrand with fixed external legs and color ordering can be obtained through the above manipulation. The reason is, for the EYM theory, the virtual particle running in the loop can be either gluon or graviton, as shown in figure 1, but the operator $D$ indicates that the forward limit is took for two external gluons thus the diagrams with only a graviton running in the loop are excluded. Now we argue that after performing the operator $D$, the only candidate for
the virtual particle in the loop is a gluon. The EYM theory includes three interaction
vertices in figure 2, these vertices indicate that for the tree EYM amplitude including only
two external gluons, one can always start from one external gluon, go along the gluon lines,
and arrive at another one. It means, after taking the forward limit for two external gluons,
a closed loop contains only gluon lines is obtained. At the 1-loop level, this observation
is sufficient to fix the virtual particle as a gluon. Thus, the operator $\mathcal{D}$ turns the internal
graviton running in the loop to a gluon. Consequently, after applying $T_0^e[+,-] = \mathcal{D}$ to
the 1-loop GR Feynman integrand, the obtained object is nothing but the 1-loop EYM
Feynman integrand with a gluon in the loop and all external particles are gravitons.

The calculation in subsection 3.2 shows that the operator $T_0^e[+,-,-,-] \mathcal{F} \text{Pf}'\Psi$ as follows

$$T_0^e[+,-,-,-] \mathcal{F} \text{Pf}'\Psi = PT(+,\sigma_1,\cdots,\sigma_m,-) \text{Pf} [\Psi_\ell]_{n-m:n-m} , \quad (4.2)$$

where the matrix $[\Psi_\ell]_{n-m:n-m}$ is obtained from $[\Psi_\ell]_{n:n}$ by deleting rows and columns labeled
by $\sigma_1, \cdots, \sigma_m$, and $\sigma_1 + n, \cdots, \sigma_m + n$. The Parke-Taylor factor $PT(+,\sigma_1,\cdots,\sigma_m,-)$
indicates the color ordering $\sigma_1,\cdots,\sigma_m$ at 1-loop level, thus the r.h.s. of (4.2) contributes
to the 1-loop single trace color ordered EYM CHY integrand, with a gluon running in the
loop. We emphasize that taking the forward limit for two external gluons for the tree EYM
CHY integrand also gives the r.h.s. of (4.2), as can be verified directly. Defining

$$T_{0C}[\sigma_1,\cdots,\sigma_m] \equiv \sum_{i=1}^m T_0^e[+,-,-,-] , \quad (4.3)$$
we arrive at the relation
\[ T^\ell_{oC}[\sigma_1, \ldots, \sigma_m] \mathcal{F} \, \text{Pf}^\ell \Psi = P T^o(\sigma_1, \ldots, \sigma_m) \mathbb{Pf}[\Psi]_{n-m:n-m}, \]  
(4.4)

where \( P T^o(\sigma_1, \ldots, \sigma_m) \) is the 1-loop Parke-Taylor factor defined in (2.24). We immediately get the conclusion that applying \( T^\ell_{oC}[\sigma_1, \ldots, \sigma_m] \) to the 1-loop GR Feynman integrand, the obtained result is the single trace 1-loop EYM Feynman integrand, with a gluon running in the loop, expressed as follows
\[ T^\ell_{oC}[\sigma_1, \ldots, \sigma_m] I^\ell_{\text{GR}}(H_n) = I^\ell_{\text{EYM}}(\sigma_1, \ldots, \sigma_m; H_{n-m}). \]  
(4.5)

This statement is valid for all lengths-\( m \) ordered sets \( \{\sigma_1, \ldots, \sigma_m\} \) with \( 0 \leq m < n \), therefore
\[ T^\ell_o[\mp, \ldots, a, b, c, \ldots, \pm] \mathcal{F} \, A^\ell_{\text{GR}}(H_n) = T^\ell_{o:abc} T^\ell_o[\mp, \ldots, a, c, \ldots, \pm] \mathcal{F} \, A^\ell_{\text{GR}}(H_n) = T^\ell_{o:abc} \mathcal{F} \, A^\ell_{\text{EYM}}(+, \ldots, a, c, \ldots, -; H_{n-m+1}). \]  
(4.6)

This equality supports the interpretation of the 1-loop insertion operator \( T^\ell_{o:abc} \): it turns the graviton \( b \) to a gluon, and inserts the leg \( b \) between \( a \) and \( c \) in the color ordering.

At the tree level, the YMS amplitude can be generated from the YM one, by applying the operator \( T^t[\mp, \sigma_1, \ldots, \sigma_m, \pm] \), as can be seen in table 3. Repeating the discussion for the EYM case, we conclude that the operator \( T^\ell_{oC}[\sigma_1, \ldots, \sigma_m] \) transmutes the 1-loop color ordered YM Feynman integrand to the 1-loop double color ordered YMS Feynman integrand, with a scalar running in the loop.

### 4.2 BI, NLSM, SG

In this subsection, we show that the operator \( L_0^c \mathcal{D} \) links the Feynman integrands for GR, BI, NLSM and SG theories together. The definition of \( L_0^c \) is the same as for the tree level case, except taking \( k_\pm = \pm \ell \).

In subsection 3.2, we found that
\[ \mathcal{D} \, \mathcal{F} \, \text{Pf}^\ell \Psi = \mathcal{F} \, T^t[\mp, \pm] \, \text{Pf}^\ell \Psi. \]  
(4.7)

Thus we immediately get
\[ L_0^c \mathcal{D} \, \mathcal{F} \, \text{Pf}^\ell \Psi = \mathcal{F} \, L^c \, T^t[\mp, \pm] \, \text{Pf}^\ell \Psi, \]  
(4.8)

since the relation \( L_0^c \mathcal{F} \bullet = \mathcal{F} L^c \bullet \) is manifest. At the tree level, the object
\[ L^c \, T^t[\mp, \pm] \, \text{Pf}^\ell \Psi = (\text{Pf}^\ell \, A)^2 \]  
(4.9)

contributes to the BI, NLSM and SG integrands, and we have
\[ L^c \, T^t[\mp, \pm] \, A^\ell_{\text{GR}}(H_{n+2}) = A^\ell_{\text{BI}}(P_{n+2}), \]
\[ L^c \, T^t[\mp, \pm] \, A^\ell_{\text{YM}}(\mp, \sigma_1, \ldots, \sigma_n, \pm) = A^\ell_{\text{NLSM}}(\mp, \sigma_1, \ldots, \sigma_n, \pm), \]
\[ L^c \, T^t[\mp, \pm] \, A^\ell_{\text{BI}}(P_{n+2}) = A^\ell_{\text{SG}}(S_{n+2}), \]  
(4.10)
as shown in table 3. Taking the forward limit for tree amplitudes gives rise to the 1-loop Feynman integrands for BI, NLSM and SG, respectively, i.e.,

$$\frac{1}{l^2} \mathcal{F} A_{\text{BI}}(P_{n+2}) = I_{\text{BI}}(P_n),$$

$$\frac{1}{l^2} \sum_{i \in \{1, \ldots, n\}} \mathcal{F} A_{\text{NLSM}(\sigma_1, \ldots, \sigma_n)} = I_{\text{NLSM}(\sigma_1, \ldots, \sigma_n)},$$

$$\frac{1}{l^2} \mathcal{F} A_{\text{SG}}(S_{n+2}) = I_{\text{SG}}(S_n).$$

(4.11)

Notice that to get the color ordered Feynman integrand $I_{\text{NLSM}(\sigma_1, \ldots, \sigma_n)}$, the cyclic summation of color orderings is required. Each one of three theories includes only one kind of particles, thus there is no ambiguity about the virtual particle running in the loop. Combining (4.8), (4.10) and (4.11) together, we obtain the following relations

$$\mathcal{L}_o^c \mathcal{D} I_{\text{GR}}(H_n) = I_{\text{BI}}(P_n),$$

$$\mathcal{L}_o^c \mathcal{D} I_{\text{YM}(\sigma_1, \ldots, \sigma_n)} = I_{\text{NLSM}(\sigma_1, \ldots, \sigma_n)},$$

$$\mathcal{L}_o^c \mathcal{D} I_{\text{BI}}(P_n) = I_{\text{SG}(S_n)}. \quad (4.12)$$

To verify the relations in (4.12), let us apply the operator $\mathcal{L}_o^c \mathcal{D}$ to $\mathcal{F} \mathbf{Pf}' \Psi$. In the subsection 3.2, we found that

$$\mathcal{D} \mathcal{F} \mathbf{Pf}' \Psi = \frac{1}{z_{+-}} \mathbf{Pf}' [\Psi_i]_{n,+,-n}, \quad (4.13)$$

where the $2(n+1) \times 2(n+1)$ matrix $[\Psi_i]_{n,+,-n}$ is obtained from $\Psi_i$ by deleting rows and columns labeled by $\epsilon_+$ and $\epsilon_-$. To continue, we need to apply $\mathcal{L}_o^c$ to $\mathbf{Pf}' [\Psi_i]_{n,+,-n}$. Since each polarization vector appears once and only once in each term of the reduced Pfaffian, the operator $\partial_{\epsilon_i, k_j}$ turns $\epsilon_i \cdot k_j$ to 1 and annihilates all other $\epsilon_i \cdot V$ simultaneously. This observation indicates that

$$\mathcal{L}_o^c \mathbf{Pf}' [\Psi_i]_{n,+,-n} = \mathbf{Pf}' \tilde{A} = -\frac{1}{z_{+-}} \mathbf{Pf} \left( \frac{A_{n \times n}}{A_{n \times n}} \right), \quad (4.14)$$

where

$$\tilde{A} \equiv \begin{pmatrix} A_{(n+2) \times (n+2)} & A_{(n+2) \times n} \\ A_{n \times (n+2)} & 0 \end{pmatrix}. \quad (4.15)$$

When calculating (4.14), a subtle point is that to avoid the ambiguity $\partial_{\epsilon_i, k_+}$ acts on $\epsilon_i \cdot k_-$ and $\partial_{\epsilon_i, k_-}$ acts on $\epsilon_i \cdot k_+$, one still need to rewrite $C_{ii}$ as in (3.30). After performing the operator $\mathcal{L}_o^c$, each $C_{ii}$ is turned to

$$C_{ii} \rightarrow \sum_{j \neq i,-} \frac{(k_j \cdot k_i)z_{-j}}{z_j z_{i-}}. \quad (4.16)$$

This object can be rewritten as

$$\sum_{j \in \{1, \ldots, n\} \setminus i} \frac{k_i \cdot k_j}{z_{ij} z_{i-}} + \frac{k_i \cdot k}{z_{i+}} - \frac{k_i \cdot \ell}{z_{i-}}. \quad (4.17)$$
via the momentum conservation law and the massless condition \( k_i^2 = 0 \), therefore vanishes automatically due to the 1-loop scattering equations in (2.16). Using the definition of Pfaffian (2.12), one can find that the non-vanishing contributions for (4.14) come from rows \( i \in \{1, \cdots, n\} \) and columns \( j \in \{n + 1, \cdots, 2n\} \), which give rise to the determinate of the matrix \( A_{n \times n} \). Thus the reduced Pfaffian of \( \tilde{A} \) can be obtained as

\[
\text{Pf} \tilde{A} = \left( -\right)^{(n)(n-1)/2 + 1} \frac{1}{2} \text{det} A_{n \times n} = \left( -\right)^{n+2} \frac{1}{2} z_+ (\text{Pf'} A)^2, \tag{4.18}
\]

where we have used \( (-)^{n(n-1)/2} = (-)^{n/2} \), due to the fact \( n \) is even. Combining (4.13) and (4.18) together, we arrive at

\[
\mathcal{L}_\epsilon^c \mathcal{D} \mathcal{F} \text{Pf'} \Psi = \left( -\right)^{n+2} \frac{1}{2} (\text{Pf'} A)^2, \tag{4.19}
\]

it shows that the operator \( \mathcal{L}_\epsilon^c \mathcal{D} \) transmutes \( \mathcal{F} \text{Pf'} \Psi \) to \( (\text{Pf'} A)^2 \), up to an overall sign. This result together with the relations in (4.12) indicate that the 1-loop CHY integrands for BI, NLSM and SG are given as

\[
\begin{align*}
\mathcal{I}^L_{\text{BI}} &= (\text{Pf'} A)^2, \\
\mathcal{I}^L_{\text{NLSM}} &= (\text{Pf'} A)^2, \\
\mathcal{I}^L_{\text{SG}} &= (\text{Pf'} A)^2, \\
\mathcal{I}^R_{\text{BI}} &= \mathcal{F} \text{Pf'} \Psi, \\
\mathcal{I}^R_{\text{NLSM}} &= \mathcal{P} \mathcal{T} (\sigma_1 \cdots, \sigma_n), \\
\mathcal{I}^R_{\text{SG}} &= (\text{Pf'} A)^2.
\end{align*} \tag{4.20}
\]

The above integrands can also be obtained by using the forward limit method, this confirm that our argument about the operator \( \mathcal{L}_\epsilon^c \mathcal{D} \) is correct.

Then, we consider applying the operator \( \mathcal{L}_\epsilon^c \mathcal{D} \) to \( \mathcal{F} \text{Pf'} \Psi \). The first step also gives (4.13). Then, we use the fact that each polarization vector appears once and only once in each term of the reduced Pfaffian, it means the operator \( \partial_{\epsilon_i} \epsilon_j \) turns \( \epsilon_i \cdot V \) to 1 and annihilates all other \( \epsilon_i \cdot V \) and \( \epsilon_j \cdot V \) simultaneously. This observation leads to

\[
\mathcal{L}_\epsilon^c \text{Pf'} \Psi|_{n,+,\cdots,=} = \text{Pf'} \tilde{A} = \frac{1}{z_+} \text{Pf} \left( \begin{array}{c|c}
A_{n \times n} & 0 \\
\hline
0 & -A_{n \times n}
\end{array} \right), \tag{4.21}
\]

where

\[
\tilde{A} \equiv \left( \begin{array}{c|c}
A_{(n+2) \times (n+2)} & 0 \\
\hline
0 & -A_{n \times n}
\end{array} \right). \tag{4.22}
\]

Evaluating (4.19) directly, we also arrive at the result in (4.19). Thus we conclude that at the 1-loop level the operator \( \mathcal{L}_\epsilon^c \mathcal{D} \) is equivalent to \( \mathcal{L}_\epsilon^c \) when applying to the object \( \mathcal{F} \text{Pf'} \Psi \), similar as the situation at the tree level.

### 4.3 EM and DBI

In this subsection, we consider the operator which transmutes the GR Feynman integrand to the EM Feynman integrand, and transmutes the BI Feynman integrand to the DBI Feynman integrand. Similar as the EYM and YMS case, the virtual particles running in the loop is not unique for these cases, as can be seen in figure 1. For the EYM and YMS cases, we have not treat all possibilities of the virtual loop particles, due to some
technic difficulties. But in this subsection, we will consider the full EM and DBI Feynman integrands with fixed external particles, which include all possibilities of virtual particles.

We begin with the EM theory that photons carry no flavor. Before discussing the desired operator, let us take a look at the forward limit for the EM case. As pointed out in subsection 2.2, the partial fraction identity indicates that each loop propagator should be cut once. The EM Feynman integrand is not color ordered, thus it does not require the cyclic summation of tree level color orderings. However, since the virtual particles running in the loop can be either gravitons or photons, in order to cut each loop propagator once, one need to take the forward limit for each of two candidates once, where one candidate is taking the forward limit for two external gravitons, and another one is for two external photons. Consequently, the 1-loop EM Feynman integrand is obtained via

\[
I_{EM}^{\epsilon}(P_{2m}; H_{n-2m}) = \frac{1}{\ell^2} \left( F_{g} A_{EM}^{\epsilon}(P_{2m}; H_{n-2m}) + F_{p} A_{EM}^{\epsilon}(P_{2m+2}; H_{n-2m}) \right)
\]

where \( F_{g} \) and \( F_{p} \) mean taking forward limit for two gravitons and two photons, respectively. The definition of the operator \( T_{X}^{\epsilon} \) can be seen in (2.34), and we have used the relation in table 3 that \( T_{X}^{\epsilon} \) transmutes the tree GR amplitude to the EM one. Without lose of generality, let us assume the operator \( T_{X}^{\epsilon} \) is defined for the length-2m set \( \{1, \cdots , 2m\} \), while the operator \( T_{X}^{\epsilon} \) is defined for \( \{1, \cdots , 2m, +, -\} \).

Now we argue that the operator \( T_{X}^{\epsilon} \) transmutes the 1-loop GR Feynman integrand \( I_{GR}^{\epsilon}(H_{2}) = (1/\ell^2) F_{g} A_{GR}^{\epsilon}(H_{n+2}) + I_{EM}^{\epsilon}(P_{2m}; H_{n-2m}) \). As will be seen soon, applying \( T_{X}^{\epsilon} \) to \( I_{GR}^{\epsilon}(H_{n}) \) gives a part of \( F_{g} T_{X}^{\epsilon} A_{GR}^{\epsilon}(H_{n+2}) \) in (4.23), while applying \( T_{X}^{\epsilon} \) to \( I_{GR}^{\epsilon}(H_{n}) \) gives \( F_{g} T_{X}^{\epsilon} A_{GR}^{\epsilon}(H_{n+2}) \) and the remaining part of \( F_{p} T_{X}^{\epsilon} A_{GR}^{\epsilon}(H_{n+2}) \).

To show this, we first decompose the operator \( T_{X}^{\epsilon} \) into two pieces as follows

\[
T_{X}^{\epsilon} = T_{X}^{\epsilon}[+, -] + \sum_{i \neq j} \left[ T_{X}^{\epsilon}[i, +] T_{X}^{\epsilon}[j, -] \right], \tag{4.24}
\]

then the object \( F_{p} T_{X}^{\epsilon} A_{GR}^{\epsilon}(H_{n+2}) \) in (4.23) is also separated into two parts. Here the operator \( T_{X}^{\epsilon}[i, j] \) is defined for the length-(2m - 2) set \( \{1, \cdots , 2m\} \backslash \{i, j\} \). For the first part, using the relation (4.7), we obtain

\[
T_{X}^{\epsilon}[i, +] T_{X}^{\epsilon}[j, -] = F_{p} T_{X}^{\epsilon} T_{X}^{\epsilon}[+, -] A_{GR}^{\epsilon}(H_{n+2}), \tag{4.25}
\]

where the commutativity between \( T_{X}^{\epsilon} \) and \( F_{p} \) have been used. Notice that the virtual particle running in the loop is fixed to be a photon after performing the operator \( D \), similar as in the EYM case discussed in subsection 4.1.

Now we turn to the second part. To treat this part, we observe that at the tree level the operator \( T^{\epsilon}[i, +] T^{\epsilon}[j, -] \) turns \( (\epsilon_{i} \cdot \epsilon_{+})(\epsilon_{j} \cdot \epsilon_{-}) \) to 1, and annihilates all other terms do not contain \( (\epsilon_{i} \cdot \epsilon_{+})(\epsilon_{j} \cdot \epsilon_{-}) \). At the 1-loop level, the corresponding object behaves as

\[
\sum_{r} (\epsilon_{i} \cdot \epsilon_{r})(\epsilon_{r} \cdot \epsilon_{j}) = \epsilon_{i} \cdot \epsilon_{j}, \tag{4.26}
\]
due to the forward limit procedure. Notice that in general the summation \( \sum_{\nu} (\epsilon^\nu_+)\epsilon^\nu_- = \eta^{\mu\nu} - \frac{l^\mu q^\nu}{l \cdot q} = \Delta^{\mu\nu}, \) (4.27)

where the null \( q \) satisfies \( \epsilon_+ \cdot q = \epsilon_- \cdot q = 0. \) Here we are allowed to drop the \( q \)-dependent term in \( \Delta^{\mu\nu} \) since its contribution vanishes on the solutions to the scattering equations; see [27]. Thus, the effect of applying \( T^t[\bar{i},+] T^t[\bar{j},-] \) at tree level is associated to applying \( T^t[\bar{i},\bar{j}] \) at 1-loop level. But one can not conclude that

\[
\mathcal{F}_p T^t[\bar{i},+] T^t[\bar{j},-] A^c_{GR}(H_{n+2}) = T^t[\bar{i},\bar{j}] \mathcal{F} A^c_{GR}(H_{n+2}).
\]

The first reason is, the object \( \epsilon_i \cdot \epsilon_j \) at 1-loop level receives contributions from either \((\epsilon_i \cdot \epsilon_+)(\epsilon_j \cdot \epsilon_-)\) or \((\epsilon_i \cdot \epsilon_-)(\epsilon_j \cdot \epsilon_+)\) at tree level, thus turning \( \epsilon_i \cdot \epsilon_j \) to 1 at 1-loop level corresponds to turning both \((\epsilon_i \cdot \epsilon_+)(\epsilon_j \cdot \epsilon_-)\) and \((\epsilon_i \cdot \epsilon_-)(\epsilon_j \cdot \epsilon_+)\) to 1 at tree level. The second reason is, the Lorentz invariant \((\epsilon_i \cdot \epsilon_j)\) in \( Y_{GR}(H_n) \) has two origins. Except \((\epsilon_i \cdot \epsilon_+)(\epsilon_j \cdot \epsilon_-)\) or \((\epsilon_i \cdot \epsilon_-)(\epsilon_j \cdot \epsilon_+)\) in the tree amplitude, \((\epsilon_i \cdot \epsilon_j)\) in the tree amplitude \( A^c_{GR}(H_{n+2}) \) also causes \((\epsilon_i \cdot \epsilon_j)\) in \( Y_{GR}(H_n) \). The operator \( \partial_{\epsilon_i \cdot \epsilon_j} \) can not distinguish these two origins. Motivated by the above discussion, we separate \( A^c_{GR}(H_{n+2}) \) into three parts \( A^c_{GR;1}(H_{n+2}), A^c_{GR;2}(H_{n+2}) \) and \( A^c_{GR;3}(H_{n+2}) \), where \( A^c_{GR;1}(H_{n+2}) \) contains \((\epsilon_i \cdot \epsilon_+)(\epsilon_j \cdot \epsilon_-)\) or \((\epsilon_i \cdot \epsilon_-)(\epsilon_j \cdot \epsilon_+)\), \( A^c_{GR;2}(H_{n+2}) \) contains \((\epsilon_i \cdot \epsilon_+)(\epsilon_j \cdot \epsilon_-)\) and \((\epsilon_i \cdot \epsilon_-)(\epsilon_j \cdot \epsilon_+)\). Since each polarization vector appears once and only once in each term of the amplitude, the above three parts have no overlap. Then we have

\[
\mathcal{F}_p T^t[\bar{i},+] T^t[\bar{j},-] + T^t[\bar{j},+] T^t[\bar{i},-] A^c_{GR;1}(H_{n+2}) = T^t[\bar{i},\bar{j}] \mathcal{F} A^c_{GR;1}(H_{n+2}),
\]

\[
a T^t[\bar{i},+] T^t[\bar{j},-] A^c_{GR;2}(H_{n+2}) = T^t[\bar{i},+] T^t[\bar{j},-] A^c_{GR;3}(H_{n+2}) = 0.
\]

On the other hand, we have

\[
\mathcal{F}_p T^t[\bar{i},\bar{j}] A^c_{GR;2}(H_{n+2}) = T^t[\bar{i},\bar{j}] \mathcal{F} A^c_{GR;2}(H_{n+2}),
\]

\[
a T^t[\bar{i},\bar{j}] A^c_{GR;1}(H_{n+2}) = T^t[\bar{i},\bar{j}] A^c_{GR;3}(H_{n+2}) = 0.
\]

Combining (4.29) and (4.30) together gives

\[
T^t[\bar{i},\bar{j}] \mathcal{F} A^c_{GR}(H_{n+2}) = \mathcal{F}_p \left( T^t[\bar{i},+] T^t[\bar{j},-] + T^t[\bar{j},+] T^t[\bar{i},-] \right) A^c_{GR;1}(H_{n+2})
\]

\[
+ \mathcal{F}_p T^t[\bar{i},\bar{j}] A^c_{GR;2}(H_{n+2})
\]

\[
= \left\{ \mathcal{F}_p \left( T^t[\bar{i},+] T^t[\bar{j},-] + T^t[\bar{j},+] T^t[\bar{i},-] \right) + \mathcal{F}_p T^t[\bar{i},\bar{j}] \right\} A^c_{GR;3}(H_{n+2}),
\]

(4.31)

where we have used the observation

\[
T^t[\bar{i},\bar{j}] \mathcal{F} A^c_{GR;3}(H_{n+2}) = 0,
\]

(4.32)
arise from the fact that $\mathcal{F} A^{\epsilon\tilde{\epsilon}}_{\text{GR},3}(\mathcal{H}_{n+2})$ does not contain $(\epsilon_i \cdot \epsilon_j)$. Using (4.31), we have

$$\sum_{\substack{i,j \in \{1,\ldots,n\} \atop i<j}} T^\epsilon_{X^i_{2m-2}} T^\epsilon_{[i,j]} \mathcal{F} A^{\epsilon\tilde{\epsilon}}_{\text{GR}}(\mathcal{H}_{n+2})$$

$$= \sum_{\substack{i,j \in \{1,\ldots,n\} \atop i<j}} \mathcal{F}_p T^\epsilon_{X^i_{2m-2}} \left( T^\epsilon_{[i,+]} T^\epsilon_{[j,-]} + T^\epsilon_{[j,+]} T^\epsilon_{[i,-]} \right) A^{\epsilon\tilde{\epsilon}}_{\text{GR}}(\mathcal{H}_{n+2})$$

$$+ \sum_{\substack{i,j \in \{1,\ldots,n\} \atop i<j}} \mathcal{F}_g T^\epsilon_{X^i_{2m-2}} T^\epsilon_{[i,j]} A^{\epsilon\tilde{\epsilon}}_{\text{GR}}(\mathcal{H}_{n+2}),$$

(4.33)

where the manifest commutativity between $T^\epsilon_{X^i_{2m-2}}$ and $\mathcal{F}_p$, $\mathcal{F}_g$ has been used. It is straightforward to recognize that

$$\sum_{\substack{i,j \in \{1,\ldots,n\} \atop i<j}} T^\epsilon_{X^i_{2m-2}} T^\epsilon_{[i,j]} = \mathcal{T}_{X^{2m}} \mathcal{F},$$

(4.34)

$$\sum_{\substack{i,j \in \{1,\ldots,n\} \atop i<j}} T^\epsilon_{X^i_{2m-2}} \left( T^\epsilon_{[i,+]} T^\epsilon_{[j,-]} + T^\epsilon_{[j,+]} T^\epsilon_{[i,-]} \right) = \sum_{\substack{i,j \in \{1,\ldots,n\} \atop i<j}} T^\epsilon_{X^i_{2m-2}} T^\epsilon_{[i,+]} T^\epsilon_{[j,-]}.$$  

Substituting this into (4.33), we immediately get

$$\mathcal{T}_{X^{2m}} \mathcal{F} A^{\epsilon\tilde{\epsilon}}_{\text{GR}}(\mathcal{H}_{n+2}) = \mathcal{F}_p \left( \sum_{\substack{i,j \in \{1,\ldots,n\} \atop i\neq j}} T^\epsilon_{X^i_{2m-2}} T^\epsilon_{[i,+]} T^\epsilon_{[j,-]} \right) A^{\epsilon\tilde{\epsilon}}_{\text{GR}}(\mathcal{H}_{n+2})$$

$$+ \mathcal{F}_g T^\epsilon_{X^{2m}} A^{\epsilon\tilde{\epsilon}}_{\text{GR}}(\mathcal{H}_{n+2}).$$

(4.35)

The operator in the big bracket at the r.h.s. is just the remaining operator in (4.24), this part together with (4.25) gives the second term in (4.23). The second part at the r.h.s. of (4.35) gives the first term in (4.23). Putting these together, we finally find

$$\mathcal{T}_{X^{2m}}(D+1) \mathcal{F} A^{\epsilon\tilde{\epsilon}}_{\text{GR}}(\mathcal{H}_{n+2}) = \left( \mathcal{F}_g T^\epsilon_{X^{2m}} + \mathcal{F}_p T^\epsilon_{X^{2m+2}} \right) A^{\epsilon\tilde{\epsilon}}_{\text{GR}}(\mathcal{H}_{n+2}),$$

(4.36)

and

$$\mathcal{T}_{X^{2m}}(D+1) I^{\epsilon\tilde{\epsilon}}_{\text{EM}}(\mathcal{H}_n) = I^{\epsilon\tilde{\epsilon}}_{\text{EM}}(\mathcal{P}_{2m};\mathcal{H}_{n-2m}).$$

(4.37)

The relation (4.36) serves as the generalization of our basic idea $\mathcal{O}_\circ \mathcal{F} \mathcal{\bullet} = \mathcal{F} \mathcal{O} \mathcal{\bullet}$.

The above relation can be verified by applying the operator $\mathcal{T}_{X^{2m}}(D+1)$ to $I^{\epsilon\tilde{\epsilon}}_{\text{GR}}(\mathcal{H}_n)$, and comparing the resulting object to $I^{\epsilon\tilde{\epsilon}}_{\text{EM}}(\mathcal{P}_{2m};\mathcal{H}_{n-2m})$ obtained through the forward limit method, similar as what we did in subsection 4.2.

Now we move to the EMf theory that photons carry flavors. For this case, another new situation occurs. As pointed out in subsection 2.2, when taking the forward limit, one should sum over the allowed flavors of legs $+$ and $-$ if they are photons. Thus the relation (4.23) should be modified as

$$I^{\epsilon\tilde{\epsilon}}_{\text{EM}}(\mathcal{P}_{2m};\mathcal{H}_{n-2m}) = \frac{1}{2^2} \left( \mathcal{F}_g T^\epsilon_{X^{2m}} + \sum_{I_+I_-} \delta_{I_+I_-} \mathcal{F}_p T^\epsilon_{X^{2m+2}} \right) A^{\epsilon\tilde{\epsilon}}_{\text{GR}}(\mathcal{H}_{n+2}),$$

(4.38)
where we have used the condition that when summing over the flavors of two internal particles, two flavors must be identified. Similar as in (4.24), we separate the operator $T^\epsilon_{X_{2m+2}}$ as

$$T^\epsilon_{X_{2m+2}} = T^\epsilon_{X_{2m}} \delta_{I_+, I_-} T^\epsilon[+] - \sum_{i,j \in \{1, \ldots, n\} \atop i \neq j} T^\epsilon_{X_{2m-2}} \delta_{I_+, I_-} T^\epsilon[i,+] T^\epsilon[j,-]. \quad (4.39)$$

Substituting the separation (4.39) into (4.38), and doing the summation over $I_+$ and $I_-$, we get

$$I^\epsilon_{E_M}(P_{2m}; H_{n-2m}) = \frac{1}{\ell^2} \left( N F_p T^\epsilon_{X_{2m}} T^\epsilon[+] - \sum_{i,j \in \{1, \ldots, n\} \atop i \neq j} T^\epsilon_{X_{2m-2}} \delta_{I_+, I_-} T^\epsilon[i,+] T^\epsilon[j,-] \right) A^\epsilon_G(H_{n+2}), \quad (4.40)$$

where $N$ stands for the number of different flavors. Using the previous technics, we can recognize these terms as

$$\frac{1}{\ell^2} \left( N F_p T^\epsilon_{X_{2m}} T^\epsilon[+] - \sum_{i,j \in \{1, \ldots, n\} \atop i \neq j} T^\epsilon_{X_{2m-2}} \delta_{I_+, I_-} T^\epsilon[i,+] T^\epsilon[j,-] \right) A^\epsilon_G(H_{n+2}) = \frac{1}{\ell^2} \left( N \delta^\epsilon_{X_{2m}} D \right) F A^\epsilon_G(H_{n+2}), \quad (4.41)$$

and

$$\frac{1}{\ell^2} \left( F_g T^\epsilon_{X_{2m}} + F_p \sum_{i,j \in \{1, \ldots, n\} \atop i \neq j} T^\epsilon_{X_{2m-2}} \delta_{I_+, I_-} T^\epsilon[i,+] T^\epsilon[j,-] \right) A^\epsilon_G(H_{n+2}) = \frac{1}{\ell^2} T^\epsilon_{X_{2m}} F A^\epsilon_G(H_{n+2}). \quad (4.42)$$

Combining them together, we find that the operator $T^\epsilon_{X_{2m}}(ND + 1)$ transmutes the 1-loop GR Feynman integrand to the 1-loop EMF Feynman integrand, formulated as

$$T^\epsilon_{X_{2m}}(ND + 1) I^\epsilon_G(H_n) = I^\epsilon_{E_M}(P_{2m}; H_{n-2m}). \quad (4.43)$$

The underlying basic of relation (4.43) is

$$T^\epsilon_{X_{2m}}(ND + 1) F^{PF} \Psi = \left( F_g T^\epsilon_{X_{2m}} + \sum_{I_+, I_-} \delta_{I_+, I_-} F_P T^\epsilon_{X_{2m+2}} \right) P F^{PF} \Psi, \quad (4.44)$$

which can also be applied to the BI and DBI theory, due to the tree level relations in table 3. Thus we also have the relation

$$T^\epsilon_{X_{2m}}(ND + 1) I^\epsilon_{BI}(P_n) = I^\epsilon_{DBI}(S_{2m}; P_{n-2m}). \quad (4.45)$$
5 Factorization of operators

In this section, we discuss the factorization of differential operators constructed in the previous two sections. Under the unitarity cut, the 1-loop Feynman integrand factorizes into two on-shell tree amplitudes, and we will show that the associated 1-loop level operator factorizes into two tree level operators parallelly. As a by product, we also demonstrate that the tree level operator factorizes into tree level operators with lower points, paralleled to the factorization of tree amplitudes. The above statement implies that both the 1-loop and tree operators can be verified by applying the tree level operator to the tree amplitude with lowest points. The structure of this section is as follows. In subsection 5.1, we give the general discussion about the unitarity cut and the factorizations of operators. Then, we show the factorizations of three operators \( T_{\omega \ell}^{\epsilon} \left[ \sigma_1, \ldots, \sigma_n \right] \), \( L_{\ell}^{\epsilon} D \) and \( T_{X_m}^{\epsilon} (D + 1) \) in subsections 5.2, 5.3 and 5.4, respectively.

5.1 General discussion

As well known, the 1-loop Feynman integrand factorizes into two tree amplitudes under the so called unitarity cut operation. For the \( s_P \) channel with respecting to the cut momentum \( P \), the unitarity cut is evaluated as

\[
\Delta A_{\omega} |_P = \int d\Omega \tilde{I}|_P ,
\]

where \( \tilde{I}|_P \equiv \ell^2 (\ell + P)^2 I \) is the cut integrand obtained via multiplying the full 1-loop Feynman integrand by two cut propagators \( \ell^2 \) and \( (\ell + P)^2 \). Here we use \( A_{\omega} \) to denote the 1-loop amplitude. The measure above is given by

\[
\int d\Omega = \int d^d\ell \delta(\ell^2)\delta((\ell + P)^2) = \int d^d\ell d^d\tilde{\ell} \delta(\ell^2)\delta(\tilde{\ell}^2)\delta(\tilde{\ell} - \ell - P) .
\]

Under the constraints of \( \delta \)-functions, \( \tilde{I}|_P \) is factorized as

\[
\lim_{\ell^2 \to 0} \lim_{(\ell + P)^2 \to 0} \tilde{I}|_P = \sum_{h_1, h_2} A_L(\cdots, (\ell + P)^{h_1}, -\ell^{h_2}) A_R(\cdots, \ell^{h_1}, -(\ell + P)^{h_2}) .
\]

Here \( \sum_{h_1, h_2} \) means sum over all possible polarization vectors or polarization tensors carried by the external legs arise from cutting the internal loop propagator. Suppose the 1-loop Feynman integrand \( I \) for the considered theory can be generated from the 1-loop Feynman integrand of another theory via the operator \( O_{\omega} \), i.e., \( I = O_{\omega} I' \), and the tree amplitude can be generated via the operator \( O \), then, under the constraints of \( \delta \)-functions, we have

\[
\lim_{\ell^2 \to 0} \lim_{(\ell + P)^2 \to 0} \ell^2 (\ell + P)^2 O_{\omega} I' = \sum_{h_1, h_2} \left( O_L A_L' (\cdots, (\ell + P)^{h_2}, -\ell^{h_1}) \right) \times \left( O_R A_R' (\cdots, \ell^{h_1}, -(\ell + P)^{h_2}) \right) .
\]

In other words, if we multiply the resulting Feynman integrand by two corresponding propagators, and setting two virtual particles running in the loop to be on-shell, the 1-loop
level operator $O_o$ will factorize into two tree level operators $O_L$ and $O_R$, where the operator $O_L$ acts on $A'_L$ and annihilates $A'_R$, while the operator $O_R$ acts on $A'_R$ and annihilates $A'_L$. We emphasize that this factorization of the operator does not mean the operator $O_o$ can be decomposed into $O_L$ and $O_R$ algebraically. It only means the l.h.s. and r.h.s. of (5.4) are equivalent. It is interesting to take a look at how such factorization realize.

To understand the factorization of the operator, let us separate the operation of unitarity cut into two steps

$$
\lim_{\ell^2 \to 0} \ell^2 (\ell + P)^2 I = \lim_{(\ell + P)^2 \to 0} (\ell + P)^2 \left( \lim_{\ell^2 \to 0} \ell^2 I \right). \tag{5.5}
$$

Without lose of generality, we can identify the loop momentum $\ell$ in the above formula as $\ell$ in the forward limit method. Then, the forward limit method indicates that

$$
\lim_{\ell^2 \to 0} \ell^2 I = \sum_{h_1} A(\cdots, -\ell^h_1, \ell^h_1), \tag{5.6}
$$

where $A(\cdots, -\ell^h_1, \ell^h_1)$ is the tree amplitude includes two on-shell external momenta $-\ell$ and $\ell$. Now we assume the Feynman integrand $I$ can be generated from $I'$ via $I = O_o I'$. For theories under consideration in this paper, our results show that (5.6) can be written as

$$
\lim_{\ell^2 \to 0} \ell^2 O_o I' = \sum_{h_1} O A'(\cdots, -\ell^h_1, \ell^h_1). \tag{5.7}
$$

Substituting this into (5.5), then substituting (5.5) into (5.4), we find that the remaining work is to show that the tree level operator $O$ factorizes into $O_L$ and $O_R$ as

$$
\lim_{(\ell + P)^2 \to 0} (\ell + P)^2 O A'(\cdots, -\ell^h_1, \ell^h_1)
= \sum_{h_2} \left( O_L A'_L(\cdots, (\ell + P)^h_2, -\ell^h_1) \right) \left( O_R A'_R(\cdots, \ell^h_1, -(\ell + P)^h_2) \right). \tag{5.8}
$$

This is nothing but the correct factorization of the tree amplitude, i.e.,

$$
\lim_{(\ell + P)^2 \to 0} (\ell + P)^2 A(\cdots, -\ell^h_1, \ell^h_1) = \sum_{h_2} A_L(\cdots, (\ell + P)^h_2, -\ell^h_1) A_R(\cdots, \ell^h_1, -(\ell + P)^h_2), \tag{5.9}
$$

thus must be correct.

### 5.2 Operator $T_{\sigma_0 C}^\epsilon[\sigma_1, \cdots, \sigma_n]$

To illustrate the idea more clear, let us take the operator $T_{\sigma_0 C}^\epsilon[\sigma_1, \cdots, \sigma_n]$ as the example. For our purpose, it is sufficient to consider $I_{YM} = T_{\sigma_0 C}^\epsilon[\sigma_1, \cdots, \sigma_n] I_{GR}^\epsilon$. Then (5.7) becomes

$$
\lim_{\ell^2 \to 0} \ell^2 T_{\sigma_0 C}^\epsilon[\sigma_1, \cdots, \sigma_n] I_{GR}^\epsilon(H_n) = \sum_{h_1} \sum_i T^\epsilon[+\sigma_i, \cdots, \sigma_{i-1}, -\sigma_i] A_{GR}^\epsilon(H_n + \{-\ell^h_1, \ell^h_1\})
= \sum_{h_1} \sum_i A_{YM}^\epsilon(\{+\}^h_1, \sigma_i, \cdots, \sigma_{i-1}, -\{\})^h_1). \tag{5.10}
$$
Now we do the second step in (5.5) for the resulting object above,

$$\lim_{(\ell + P)^2 \to 0} (\ell + P)^2 \left( \sum_{h_1} \sum_i \mathcal{A}_{\text{YM}}^\sim((+)^{h_1}, \sigma_i, \ldots, \sigma_{i-1}, (-)^{h_1}) \right).$$

(5.11)

For the color ordered amplitude, we can assume $P = \sum_{a=k}^l k_{\sigma_a}$. It is straightforward to observe that only the $i = k$ term in the summation over $i$ provides non-vanishing contribution, due to the constraint $(\ell + P)^2 = 0$. Thus our current aim is to show the relation

$$\lim_{(\ell + P)^2 \to 0} (\ell + P)^2 \mathcal{T}'[\mp, \sigma_k, \cdots, \sigma_{k-1}, -] \mathcal{A}_{\text{GR}}^\sim(H_n + \{-\ell^{h_1}, \ell^{h_1}\})$$

$$= \sum_{h_2} \mathcal{A}_{\text{YM},L}^\sim((P^+)^{h_2}, \sigma_i, \cdots, \sigma_{k-1}, (-)^{h_1}) \mathcal{A}_{\text{YM},R}^\sim((+)^{h_1}, \sigma_k, \cdots, \sigma_{i-1}, (P^-)^{h_2}),$$

(5.12)

This is just the tree level factorization

$$\lim_{(\ell + P)^2 \to 0} (\ell + P)^2 \mathcal{A}_{\text{YM}}^\sim((+)^{h_1}, \sigma_k, \cdots, \sigma_{k-1}, (-)^{h_1})$$

(5.13)

$$= \sum_{h_2} \mathcal{A}_{\text{YM},L}^\sim((P^+)^{h_2}, \sigma_i, \cdots, \sigma_{k-1}, (-)^{h_1}) \mathcal{A}_{\text{YM},R}^\sim((+)^{h_1}, \sigma_k, \cdots, \sigma_{i-1}, (P^-)^{h_2}),$$

thus must be true. Here the legs with momenta $(\ell + P)$ and $-(\ell + P)$ are denoted by $P^+$ and $P^-$ in the color orderings, respectively.

Although the factorization of the operator $\mathcal{T}'[\mp, \sigma_k, \cdots, \sigma_{k-1}, -]$ at tree level is ensured by the factorization of tree amplitude, there is no harm to see how it realize. The following treatment is similar as that in [28]. Let us choose the formula of operator $\mathcal{T}'[\mp, \sigma_k, \cdots, \sigma_{k-1}, -]$ to be

$$\mathcal{T}'[\mp, \sigma_k, \cdots, \sigma_{k-1}, -] = \left( \prod_{i=k}^{k-2} I_{+\sigma_i, \sigma_{i+1}} \right) I_{+\sigma_{k-1}} - I_{+\sigma_k} - \mathcal{T}'[\mp, -],$$

(5.14)

and denote the polarization vectors associated to $(\ell + P)$ and $-(\ell + P)$ by $\epsilon_{P^+}$ and $\epsilon_{P^-}$, respectively. We apply the operator $\mathcal{T}'[\mp, \sigma_k, \cdots, \sigma_{k-1}, -]$ chosen above to the factorized formula of $\mathcal{A}_{\text{GR}}^\sim(H_n + \{-\ell^{h_1}, \ell^{h_1}\})$ which is given as

$$\lim_{(\ell + P)^2 \to 0} (\ell + P)^2 \mathcal{A}_{\text{GR}}^\sim(H_n + \{-\ell^{h_1}, \ell^{h_1}\})$$

(5.15)

$$= \sum_{h_2} \mathcal{A}_{\text{GR},L}^\sim(k_{\sigma_i}, \cdots, k_{\sigma_{k-1}}, (\ell + P)^{h_2}, -\ell^{h_1}) \mathcal{A}_{\text{GR},R}^\sim(k_{\sigma_k}, \cdots, k_{\sigma_{i-1}}, -(\ell + P)^{h_2}, \ell^{h_1}).$$

Using the relation

$$\sum_r (\epsilon_{P^+}^r, \epsilon_{P^-}^r)^{r\mu} A_{\mu\nu} = \eta^{\mu\nu} A_{\mu\nu}$$

(5.16)

for on-shell states, we see that the effect of applying $\mathcal{T}'[\mp, -]$ is turning both $(\epsilon_+ \cdot \epsilon_{P^+})$ and $(\epsilon_- \cdot \epsilon_{P^-})$ to 1 and removing the summation over $r$. In other words, the operator $\mathcal{T}'[\mp, -]$ turns $\sum_{h_2}$ to $\sum_{h_2}$, and factorize into $\mathcal{T}'[\mp, P^+]$ and $\mathcal{T}'[P^+, -]$. Obviously, the
operator $T^i[+,P_-]$ acts on $\mathcal{A}_{GR;R}^{\tilde{\epsilon}}$ and annihilates $\mathcal{A}_{GR;L}^{\tilde{\epsilon}}$, while the operator $T^i[P_+,+]$ acts on $\mathcal{A}_{GR;R}^{\epsilon}$ and annihilates $\mathcal{A}_{GR;L}^{\epsilon}$. In the above argument, the fact that each polarization vector appears once and only once in each term of the amplitude has been used. To continue, we observe that $T_{+\sigma_1}^i$ with $i \in \{k, \cdots, l - 1\}$ acts on $\mathcal{A}_{GR;R}^{\tilde{\epsilon}}$ and annihilates $\mathcal{A}_{GR;L}^{\tilde{\epsilon}}$, while those with $i \in \{l, \cdots, k - 1\}$ acts on $\mathcal{A}_{GR;R}^{\epsilon}$ and annihilates $\mathcal{A}_{GR;L}^{\epsilon}$, based on whether the amplitude $\mathcal{A}_{GR;R}^{\tilde{\epsilon}}$ or $\mathcal{A}_{GR;R}^{\epsilon}$ includes the polarization vector $\epsilon_i$. Thus, it is safe to replace $\partial_{\epsilon_{\sigma_i}, k_i}$ acts on $\epsilon_{\sigma_i} \cdot k_i$, as what we did in section 3. To regroup these insertion operators so that each operator can be interpreted appropriately, some treatments are in order. For the operator $T_{+\sigma_{l-1}}^i$, we rewrite it as

$$T_{+\sigma_{l-1}}^i = T_{+\sigma_{l-1}P_-}^i + T_{+\sigma_{l-1}}^i P_-.$$  

(5.17)

The operator $T_{+\sigma_{l-1}P_-}$ can be interpreted as inserting the leg $\sigma_{l-1}$ between $+ \cdot P_-$. Since the momentum $k_{\sigma_i}$ enters $\mathcal{A}_{GR;R}^{\tilde{\epsilon}}$ only through $-P = \sum_{i=0}^{k-1} k_{\sigma_i}$, we have

$$\partial_{\epsilon_{\sigma_{l-1}}, -\ell \cdot P_+} \mathcal{A}_{GR;R}^{\epsilon}(k_{\sigma_1}, \cdots, k_{\sigma_{l-1}}, -(\ell + P)k_1, \ell k_1) = \partial_{\epsilon_{\sigma_{l-1}}, k_{\sigma_1}} \mathcal{A}_{GR;R}^{\tilde{\epsilon}}(k_{\sigma_1}, \cdots, k_{\sigma_{l-1}}, -(\ell + P)k_1, \ell k_1),$$  

(5.18)

thus the operator $T_{+\sigma_{l-1}P_-}$ annihilates only $\mathcal{A}_{GR;R}^{\tilde{\epsilon}}$, but also $\mathcal{A}_{GR;R}^{\epsilon}$. Thus, when acting on $\mathcal{A}_{GR;R}^{\tilde{\epsilon}}$, one can replace $T_{+\sigma_{l-1}}^i$ by $T_{+\sigma_{l-1}}^i P_-$. Then, we arrive at the combinatorial operator

$$\left( \prod_{i=k}^{l-2} T_{+\sigma_{i+1}}^i \right) T_{+\sigma_{l-1}P_-}^i T^i[+,P_-] = T^i[+,\sigma_1, \cdots, \sigma_{l-1}, P_-],$$  

(5.19)

which transmutes $\mathcal{A}_{GR;R}^{\epsilon}$ to $\mathcal{A}_{YM;R}^\epsilon(\sigma_i, \cdots, \sigma_{l-1}, (P_+)\sigma_{l-1})$, and annihilates $\mathcal{A}_{GR;L}^{\tilde{\epsilon}}$. Then we turn to the insertion operators $T_{+\sigma_{i+1}}^i$ with $i \in \{l, \cdots, k - 1\}$. Since the momentum $k_\ell = -\ell$ has been removed via the momentum conservation, the momentum $\ell$ enters $\mathcal{A}_{GR;R}^{\tilde{\epsilon}}$ only through $(\ell + P)$, thus, when applying $\partial_{\epsilon_{\sigma_i}, \ell}$ to $\mathcal{A}_{GR;R}^{\tilde{\epsilon}}$, we have

$$\partial_{\epsilon_{\sigma_i}, \ell} \mathcal{A}_{GR;L}^{\tilde{\epsilon}}(k_{\sigma_1}, \cdots, k_{\sigma_{k-1}}, (\ell + P)\ell k_1) = \partial_{\epsilon_{\sigma_{k-1}}, (-\ell + P)\sigma_{k-1}} \mathcal{A}_{GR;R}^{\tilde{\epsilon}}(k_{\sigma_1}, \cdots, k_{\sigma_{k-1}}, (\ell + P)\ell k_1).$$  

(5.20)

This equality allows us to interpret each $T_{+\sigma_{i+1}}^i$ with $i \in \{l, \cdots, k - 1\}$ as $T_{P_+, \sigma_{i+1}}^i$. But we still need to seek the correct interpretation of $T_{P_+, \sigma_{k-1}, \sigma_{k}}$, since $k_{\sigma_k}$ is included in $\mathcal{A}_{GR;R}^{\tilde{\epsilon}}$ rather than in $\mathcal{A}_{GR;R}^{\epsilon}$. Since $k_\ell = -\ell$ has been removed, we have

$$\partial_{\epsilon_{\sigma_k}, -\ell} \mathcal{A}_{GR;L}^{\tilde{\epsilon}}(k_{\sigma_1}, \cdots, k_{\sigma_{k-1}}, (\ell + P)\ell k_1) = \partial_{\epsilon_{\sigma_{k-1}}, \epsilon_{\sigma_k}} \mathcal{A}_{GR;R}^{\tilde{\epsilon}}(k_{\sigma_1}, \cdots, k_{\sigma_{k-1}}, (\ell + P)\ell k_1) = 0,$$  

(5.21)

thus it is safe to replace $T_{P_+, \sigma_{k-1}, \sigma_{k}}$ by $T_{P_+, \sigma_{k-1}}$. Consequently, we get another combinatorial operator

$$\left( \prod_{i=l}^{k-2} T_{P_+, \sigma_{i+1}}^i \right) T_{P_+, \sigma_{k-1}} T^i[+,P_-] = T^i[+,\sigma_1, \cdots, \sigma_{k-1}, P_-].$$  

(5.22)
which transmutes $A_{GR:L}^{\epsilon,x}$ to $A_{YM:L}^{\epsilon,x}((P_e)^{h_2},\sigma_1,\ldots,\sigma_{k-1},(-)^{h_1})$, and annihilates $A_{GR:R}^{\epsilon,x}$. Based on the above discussion, we conclude that under the on-shell condition $(\ell + P)^2 = 0$, the operator $T^i[+,\sigma_k,\ldots,\sigma_{k-1},-]$ factorizes into

$$O_L = T^i[P_+,\sigma_1,\ldots,\sigma_{k-1},-], \quad O_R = T^i[+,\sigma_k,\ldots,\sigma_{l-1},P_-],$$

and transmutes the factorization of GR amplitude to the factorization of color ordered YM amplitude.

5.3 Operator $L_0^\epsilon \mathcal{D}$

The next example is the factorization of operator $L_0^\epsilon \mathcal{D}$. We will demonstrate it by considering the relation $I^\epsilon_{BL} = L_0^\epsilon \mathcal{D} I^\epsilon_{GR}$. In the case under consideration, (5.7) becomes

$$\lim_{\ell^2 \to 0} \ell^2 L_0^\epsilon \mathcal{D} I^\epsilon_{GR}(H_n) = \sum_{h_1} L^\epsilon T^i[+,±] A_{GR}^{\epsilon,x}(H_n + \{-\ell^{h_1},\ell^{h_1}\})$$

$$= \sum_{h_2} \left( O_L A_{GR:L}^{\epsilon,x}(k_{\sigma_1},\ldots,k_{\sigma_{k-1}},(\ell + P)^{h_2},-\ell^{h_1}) \right)$$

$$\times \left( O_R A_{GR:R}^{\epsilon,x}(k_{\sigma_k},\ldots,k_{\sigma_{l-1}},-(\ell + P)^{h_2},\ell^{h_1}) \right),$$

which is just the tree level factorization

$$\lim_{(\ell + P)^2 \to 0} (\ell + P)^2 A_{BL}^{\epsilon,x}(P_n + \{-\ell^{h_1},\ell^{h_1}\})$$

$$= \sum_{h_2} A_{BL:L}^{\epsilon,x}(k_{\sigma_1},\ldots,k_{\sigma_{k-1}},(\ell + P)^{h_2},-\ell^{h_1}) A_{BL:R}^{\epsilon,x}(k_{\sigma_k},\ldots,k_{\sigma_{l-1}},-(\ell + P)^{h_2},\ell^{h_1}).$$

Again, the factorization of the operator $L^\epsilon T^i[+,±]$ in (5.25) is ensured by the factorization of tree amplitude.

It is straightforward to understand the factorization of the operator $L^\epsilon T^i[+,±]$ at tree level. In the previous subsection, we proved that the operator $T^i[+,±]$ factorizes into $T^i[+,P_-]$ and $T^i[P_+,+]$ under the on-shell condition $(\ell + P)^2 = 0$. One can regroup $L^\epsilon$ to be $L^\epsilon = L_L^\epsilon L_R^\epsilon$ directly, by considering whether $A_{GR:L}^{\epsilon,x}$ or $A_{GR:R}^{\epsilon,x}$ contains the polarization vector $\epsilon_\sigma$. We emphasize that two definitions $L^\epsilon$ and $\tilde{L}^\epsilon$ in (2.32) leads to the same factorization. Notice that when considering $L^\epsilon$, for the operator $(k_i \cdot k_j)\partial_{\epsilon_i,\epsilon_j}$ with $\epsilon_i \in A_{GR:L}$ and $\epsilon_j \in A_{GR:R}$, one can not use the technic of separating $T^i[+,±]$ into $T^i[P_+,±]$ and $T^i[+,P_-]$ to separate $\partial_{\epsilon_i,\epsilon_j}$. The reason is, the summation $\sum_{\nu} (\epsilon_{P_+}^\mu)(\epsilon_{P_-}^\nu)$ has been removed when separating $T^i[+,±]$. Thus, the operator $(k_i \cdot k_j)\partial_{\epsilon_i,\epsilon_j}$ across $A_{GR:L}^{\epsilon,x}$ and $A_{GR:R}^{\epsilon,x}$ annihilates both two amplitudes. After regrouping $L^\epsilon$, we find that the operator $L_L^\epsilon T^i[+,±]$ factorizes into

$$O_L = L_L^\epsilon T^i[P_+,±], \quad O_R = L_R^\epsilon T^i[+,P_-].$$
5.4 Operator $\mathcal{T}_{X_{2m}}^{\ell} (D+1)$

The final example is the operator $\mathcal{T}_{X_{2m}}^{\ell} (D+1)$, which links the 1-loop GR and EM Feynman integrands together as $I_{\text{EM}}^{\ell}(P_{2m};H_{n-2m}) = \mathcal{T}_{X_{2m}}^{\ell} (D+1) I_{\text{GR}}^{\ell}(H_{n})$. The factorization of the operator $\mathcal{T}_{X_{2m}}^{\ell} (N D + 1)$ can be discussed similarly. For latter convenience, let us assume that the external gravitons in the set $\{1, \ldots, 2m\}$ are turned to photons by the operator $\mathcal{T}_{X_{2m}}^{\ell} (D+1)$. For the current example, the new situation occurs. A special cut should be recognized not only by the momenta channel, but also what kind of cut virtual particle. We need to discuss the following three cases, which are cutting two gravitons, cutting one graviton and one photon, as well as cutting two photons.

As before, we start by doing the first step in (5.5). Using (4.23) and (4.37), we know that

$$
\lim_{\ell^2 \to 0} \ell^2 \mathcal{T}_{X_{2m}}^{\ell} (D+1) I_{\text{GR}}^{\ell}(H_n) = \sum_{\ell'_i} \mathcal{T}_{X_{2m}}^{\ell} A_{\text{GR}}^{\ell}(H_n + \{-\ell'_i, \ell'_i\})
$$

if we cut two gravitons. We also have

$$
\lim_{\ell^2 \to 0} \ell^2 \mathcal{T}_{X_{2m}}^{\ell} (D+1) I_{\text{GR}}^{\ell}(H_n) = \sum_{\ell'_i} \mathcal{T}_{X_{2m}}^{\ell} A_{\text{EM}}^{\ell}(P_{2m};H_{n-2m} + \{-\ell'_i, \ell'_i\})
$$

if we cut two photons.

Now we do the second step in (5.5). For the first case (5.28), if we cut two gravitons in the second step, all $T_{\varepsilon}^{i[a,b]}$ with $\epsilon_a \in A_{\text{GR};L}^{\varepsilon}$ and $\epsilon_b \in A_{\text{GR};R}^{\varepsilon}$ annihilates both two amplitudes, thus the effective operator becomes

$$
\mathcal{T}_{X_{2m}}^{\ell} \left| \text{effective} \right. = \left( \sum_{\rho_L} \prod_{i_k,j_k \in \rho_L} T_{\varepsilon}^{i_k,j_k} \right) \left( \sum_{\rho_R} \prod_{i_l,j_l \in \rho_R} T_{\varepsilon}^{i_l,j_l} \right)
$$

(5.30)

where $m_L$ and $m_R$ denote the number of photons in $A_{\text{EM};L}$ and $A_{\text{EM};R}$ respectively, and satisfy $m_L + m_R = 2m$. More explicitly, we have assumed that the operator $\mathcal{T}_{X_{2m}}^{\ell}$ turns external gravitons belong to $\{1, \ldots, 2m\}$ to photons, and now we divide $\{1, \ldots, 2m\}$ into $\{a_1, \ldots, a_{m_L}\}$ and $\{b_1, \ldots, b_{m_R}\}$, where the external graviton labeled by $a_i$ is included in $A_{\text{GR};L}^{\varepsilon}$, while that labeled by $b_i$ is included in $A_{\text{GR};R}^{\varepsilon}$. Partitions $\rho_L$ and $\rho_R$ are understood as partitions for $\{a_1, \ldots, a_{m_L}\}$ and $\{b_1, \ldots, b_{m_R}\}$, respectively. Thus, for this case, the operator $\mathcal{T}_{X_{2m}}^{\ell}$ factorizes into

$$
\mathcal{O}_L = \mathcal{T}_{X_{m_L}}^{\ell} \quad \mathcal{O}_R = \mathcal{T}_{X_{m_R}}^{\ell}
$$

(5.31)

If we cut two photons in the second step, the effective part of the operator $\mathcal{T}_{X_{2m}}^{\ell}$ should contain one and only one $T_{\varepsilon}^{i[a,b]}$ with $\epsilon_a \in A_{\text{GR};L}^{\varepsilon}$ and $\epsilon_b \in A_{\text{GR};R}^{\varepsilon}$, and we can use (5.16)
to see that $\mathcal{T}^e[a,b]$ factorizes into $\mathcal{T}^e[a, P_+]$ and $\mathcal{T}^e[P_-, b]$. Notice that such decomposition can be used only once, as discussed in the previous subsection. Then we find

$$\mathcal{T}^e_{2m} \mid \text{effective} = \sum_{a \in \{a_1, \ldots, a_{2m_L}\}} \mathcal{T}^e[a, P_+] \prod_{i, j, k} \mathcal{T}^e[i, j, k] \mathcal{T}^e[P_-, b] \prod_{i, j, l} \mathcal{T}^e[i, j, l] - \mathcal{T}^e_{m_L+1} \mathcal{T}^e_{m_R+1}. \quad (5.32)$$

Here $\rho^e_L$ and $\rho^e_R$ are understood as partitions for $\{a_1, \ldots, a_{m_L}\} \setminus a$ and $\{b_1, \ldots, b_{m_R}\} \setminus b$, respectively. Thus the operator $\mathcal{T}^e_{2m}$ factorizes into

$$\mathcal{O}_L = \mathcal{T}^e_{m_L+1}, \quad \mathcal{O}_R = \mathcal{T}^e_{m_R+1}. \quad (5.33)$$

Similar discussion holds for the second case (5.29). For the second case, if we cut two gravitons at the second step, we find

$$\mathcal{T}^e_{2m+2} \mid \text{effective} = \left( \sum_{\rho^a_L, \rho^b_R} \prod_{i, j, k} \mathcal{T}^a[i, j, k] \mathcal{T}^b[i, j, l] \right) - \mathcal{T}^e_{m_L+1} \mathcal{T}^e_{m_R+1}. \quad (5.34)$$

Here we use the notations $\mathcal{T}^e_{m_L+1}$ and $\mathcal{T}^e_{m_R+1}$ to distinguish them from $\mathcal{T}^e_{m_L+1}$ and $\mathcal{T}^e_{m_R+1}$ in (5.33). This formula should be understood as follows. The operator $\mathcal{T}^e_{2m+2}$ turns external gravitons in $\{1, \ldots, 2m, +, -\}$ to photons, and we divide $\{1, \ldots, 2m\}$ into $\{a_1, \ldots, a_{m_L}\}$ and $\{b_1, \ldots, b_{m_R}\}$ as before. Then $\rho^a_L$ and $\rho^b_R$ are partitions for $\{a_1, \ldots, a_{m_L}, -\}$ and $\{b_1, \ldots, b_{m_R}, +\}$, respectively. The factorized formula in (5.34) is the similar as that in (5.33). This similarity is quite natural, since from the unitarity cut point of view, both two cases are cutting one graviton and one photon. Cutting two photons at the second step gives

$$\mathcal{T}^e_{2m+2} \mid \text{effective} = \sum_{a \in \{a_1, \ldots, a_{m_L}, -\}} \mathcal{T}^e[a, P_+] \prod_{i, j, k} \mathcal{T}^e[i, j, k] \mathcal{T}^e[P_-, b] \prod_{i, j, l} \mathcal{T}^e[i, j, l] - \mathcal{T}^e_{m_L+1} \mathcal{T}^e_{m_R+2}. \quad (5.35)$$

thus the operator $\mathcal{T}^e_{2m+2}$ factorizes into $\mathcal{T}^e_{m_L+2}$ and $\mathcal{T}^e_{m_R+2}$. Here $\rho^a_L$ and $\rho^b_R$ are partitions of $\{a_1, \ldots, a_{m_L}, -\} \setminus a$ and $\{b_1, \ldots, b_{m_R}, +\} \setminus b$, respectively.

6 Summary and discussions

In this paper, we have constructed the 1-loop level differential operators which transmute the 1-loop GR Feynman integrand to the Feynman integrands of various theories, include
Feynman integrand & $\mathcal{O}_0^\epsilon$ & $\mathcal{O}_0^\tilde{\epsilon}$ \\
\hline
\begin{align*}
I_{\text{GR}}^\epsilon(H_n) & \equiv & I \\
I_{\text{seEYM}}^\epsilon(\bar{\sigma}_m; H_{n-m}) & \equiv & \mathcal{T}_0^\epsilon[\bar{\sigma}_m] \\
I_{\text{EMf}}^\epsilon(P_{2m}; H_{n-2m}) & \equiv & \mathcal{T}_{X_{2m}}^\epsilon(N \tilde{D} + 1) \\
I_{\text{EM}}^\epsilon(P_{2m}; H_{n-2m}) & \equiv & \mathcal{T}_{X_{2m}}^\tilde{\epsilon}(\tilde{D} + 1) \\
I_{\text{BI}}(P_n) & \equiv & \mathcal{L}_0^\epsilon \tilde{D} \\
I_{\text{YM}}(\bar{\sigma}_n) & \equiv & \mathcal{T}_0^\epsilon[\bar{\sigma}_n] \\
I_{\text{seYMS}}^\epsilon(\bar{\sigma}_m; G_{n-m}[\sigma'_n]) & \equiv & \mathcal{T}_0^\epsilon[\sigma'_n] \\
I_{\text{NLSM}}(\bar{\sigma}_n) & \equiv & \mathcal{L}_0^\epsilon \tilde{D} \\
I_{\text{BAS}}(\bar{\sigma}_n[\sigma'_n]) & \equiv & \mathcal{T}_0^\epsilon[\sigma'_n] \\
I_{\text{DBI}}(S_{2m}; P_{n-2m}) & \equiv & \mathcal{L}_0^\epsilon \tilde{D} & \mathcal{T}_{X_{2m}}^\epsilon(N \tilde{D} + 1) \\
I_{\text{SG}}(S_n) & \equiv & \mathcal{L}_0^\epsilon \tilde{D} & \mathcal{T}_0^\epsilon[\sigma'_n] \\
\end{align*}

Table 4. Unifying relations at 1-loop level.

Einstein-Yang-Mills theory, Einstein-Maxwell theory, pure Yang-Mills theory, Yang-Mills-scalar theory, Born-Infeld theory, Dirac-Born-Infeld theory, bi-adjoint scalar theory, non-linear sigma model, as well as special Galileon theory. Similar as the tree level formula (2.36), the 1-loop level relations can be summarized as

$$I = \mathcal{O}_0^\epsilon \mathcal{O}_0^\tilde{\epsilon} I_{\text{GR}}^\epsilon.$$  \hfill (6.1)

Operators $\mathcal{O}_0^\epsilon$ and $\mathcal{O}_0^\tilde{\epsilon}$ for different theories are listed in table 4. Comparing table 4 with table 3, we see that the 1-loop level relations are paralleled to the tree level relations. Based on the relations in table 4, one can construct the unified web for these theories, as shown in figure 3. In this web, different kinds of lines represents different operators. Along a line from theory A to theory B, one can generate the 1-loop Feynman integrand $I_B$, by applying the corresponding operator to $I_A$. For example, there is a double straight line from EMf to DBI, thus we have the relation

$$I_{\text{DBI}}^\tilde{\epsilon}(S_{2m}; P_{n-2m}) = \mathcal{L}_0^\epsilon \mathcal{D} I_{\text{EMf}}^\epsilon(P_{2m}; H_{n-2m}).$$  \hfill (6.2)

We also discussed the factorization of differential operators under the well known unitarity cut. Our result shows that the 1-loop level operator factorizes into two tree level pieces, paralleled to the factorization of amplitudes. As a by product, we also found the mechanism of the factorization of tree level operators. These properties propose an alternative way to verify the operators: applying the tree level operator to the lowest points tree level amplitudes. A natural conjecture is, maybe one can construct a general operator recursively, from the lowest points operator, similar as the well known on-shell recursion relation for constructing amplitudes.
Figure 3. Unified web for 1-loop Feynman integrands. The bold straight line represents the operator $T_{\sigma_n}$, the straight line represents the operator $T_{m}$, the double straight line represents the operator $L_D$, the dashed line represents the operator $T_{X_2m}(D+1)$, the double dashed line represents the operator $T_{X_2m}(N D+1)$, the thin dashed line represents the insertion operators.

For the EYM theory, in this paper we only consider the single trace Feynman integrands with a virtual gluon running in the loop, and similar does the YMS theory. We have not discussed the more general case, due to some technical difficulties those we do not know how to overcome. The general multiple traces case with arbitrary virtual particle in the loop is left to be the future direction.

The basic idea used in this paper is to find the operator $O_s$ satisfying $O_s F \bullet = F O \bullet$, where $O$ is the already known tree level operator. This idea based on the validity of the forward limit method. However, as mentioned in section 1, the forward limit method is not the only candidate for generating the 1-loop CHY formula. Thus, how to reveal relations in table 4 and figure 3 in the ambitwistor string framework is an interesting question. The Feynman integrands provided by the current 1-loop CHY formula in the sense of $Q$-cut [29, 30]. They include propagators linear in $\ell$ rather than quadratic, and are related to the standard ones via the partial fraction identity. Until now we do not have a systematical way to construct the CHY formula which leads to Feynman integrands with propagators quadratic in $\ell$. Searching the differential operators link Feynman integrands with quadratic propagators together, via a path which is independent of the CHY formula, is another interesting challenge.
