HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
ABSTRACT. We study three fundamental topics in the representation theory of
disconnected algebraic groups whose identity component is reductive: (i) the
classification of irreducible representations; (ii) the existence and properties of
Weyl and dual Weyl modules; and (iii) the decomposition map relating repre-
sentations in characteristic 0 and those in characteristic $p$ (for groups defined
over discrete valuation rings). For each of these topics, we obtain natural
generalizations of the well-known results for connected reductive groups.

1. Introduction

Let $G$ be a (possibly disconnected) affine algebraic group over an algebraically
closed field $k$, and let $G^\circ$ be its identity component. We call $G$ a (possibly) dis-
connected reductive group if $G^\circ$ is reductive. The goal of this paper is to extend a
number of well-known foundational facts about connected reductive groups to the
disconnected case.

Such groups occur naturally, even when one is primarily interested in connected
reductive groups. Namely, for a connected reductive group $H$, the stabilizer $H^x$
of a nilpotent element in the Lie algebra of $H$ may be disconnected. Let $H^x_{\text{unip}}$ be
its unipotent radical; then $H^x/H^x_{\text{unip}}$ is a disconnected reductive group. The study
of (the derived category of) coherent sheaves on the nilpotent cone $N$ of $H$, and
in particular of perverse-coherent sheaves on $N$, leads naturally to questions about
representations of $H^x/H^x_{\text{unip}}$. See [AHR] for some questions of this form, and for
some applications of the results of this paper.

The present paper contains three main results:

1. We classify the irreducible representations of $G$ in terms of those of $G^\circ$, via
   an adaptation of Clifford theory (Theorem 2.16).
2. Assuming that the characteristic of $k$ does not divide $|G/G^\circ|$, we prove that
   the category of finite-dimensional $G$-modules has a natural structure of a
   highest-weight category (Theorem 3.7).
3. Starting from a disconnected reductive group scheme over an extension of
   the $p$-adic integers (with algebraically closed residue field), one obtains a
   “decomposition map” relating the Grothendieck groups of representations
   in characteristic 0 and in characteristic $p$. We prove that this map is an
   isomorphism.

P.A. was supported by NSF Grant Nos. DMS-1500890 and DMS-1802241. This project has
received funding from the European Research Council (ERC) under the European Union’s Horizon
2020 research and innovation programme (grant agreement No. 677147).
These results are certainly not surprising, and some of them may be known to experts, but we are not aware of a reference that treats them in the detail and generality needed for the applications in [AHR].

Acknowledgments. We thank Jens Carsten Jantzen a helpful conversation.

2. Classification of simple representations

In this section we consider (affine) algebraic groups over an arbitrary algebraically closed field $k$. Our goal is to describe the representation theory of a disconnected algebraic group $G$ whose neutral connected component $G^o$ is reductive in terms of the representation theory of $G^o$, via a kind of Clifford theory.

2.1. Twist of a representation by an automorphism. Let $G$ be an algebraic group, $\varphi : G \to G$ an automorphism, and let $\pi = (V, \varrho)$ be a representation of $G$. Then we define the representation $\varphi \pi$ as the pair $(V, \varrho \circ \varphi^{-1})$. (Below, we will most of the time write $V$ for $\pi$, and $\varphi V$ for $\varphi \pi$.) It is straightforward to check that if $\psi : G \to G$ is a second automorphism, then we have

$$\psi (\varphi \pi) = \varphi \varrho \pi.$$

If $f : \pi \to \pi'$ is a morphism of $G$-representations, then the same linear map defines a morphism of $G$-representations $\varphi \pi \to \varphi \pi'$, which will sometimes be denoted $\varphi f$.

Lemma 2.1. Let $H \subset G$ be a subgroup, and $(V, \varrho)$ be a representation of $H$. Then there exists a canonical isomorphism of $G$-modules

$$\varphi \text{Ind}_H^G(V, \varrho) \cong \text{Ind}_{\varphi(H)}^G(V, \varrho \circ \varphi^{-1}).$$

Proof. By definition, we have

$$\text{Ind}_H^G(V, \varrho) = \{ f : G \to V \mid \forall h \in H, f(gh) = \varrho(h^{-1})f(g) \},$$

$$\text{Ind}_{\varphi(H)}^G(V, \varrho \circ \varphi^{-1}) = \{ f : G \to V \mid \forall h \in \varphi(H), f(gh) = \varrho \circ \varphi^{-1}(h^{-1})f(g) \}.$$

Here, in both cases the functions are assumed to be algebraic, and the $G$-action is defined by $(g \cdot f)(h) = f(g^{-1}h)$. We have a natural isomorphism of vector spaces

$$\text{Ind}_H^G(V, \varrho) \cong \text{Ind}_{\varphi(H)}^G(V, \varrho \circ \varphi^{-1})$$

sending $f$ to $f \circ \varphi^{-1}$. It is straightforward to check that this morphism is an isomorphism of $G$-modules from $\varphi \text{Ind}_H^G(V, \varrho)$ to $\text{Ind}_{\varphi(H)}^G(V, \varrho \circ \varphi^{-1})$. \hfill $\square$

Remark 2.2. More generally, if $G'$ is another algebraic group and $\varphi : G \to G'$ is an isomorphism, for any $G$-module $\pi$ we can consider the $G'$ module $\varphi \pi$ defined as above. Then the same arguments as for Lemma 2.1 show that we have $\varphi \text{Ind}_{H}^{G'}(\pi) \cong \text{Ind}_{\varphi(H)}^{G'}(\varphi \pi)$.

In particular, assume that we are given an algebraic group $G'$ and an embedding of $G$ as a normal subgroup of $G'$. Then for any $g \in G'$, we have an automorphism $\text{ad}(g)$ of $G$ sending $h$ to $ghg^{-1}$. In this setting, we will write $\varrho V$ for $\text{ad}(\varrho) V$, and $gf$ for $\text{ad}(g)f$. Then for $g, h \in G'$, since $\text{ad}(g) \circ \text{ad}(h) = \text{ad}(gh)$, (2.1) translates to

$$g(h V) = \varrho h V.$$

The verification of the following lemma is straightforward.

Lemma 2.3. Let $(V, \varrho)$ be a representation of $G$. Then if $g \in G$, $\varrho(g^{-1})$ induces an isomorphism $V \to \varrho V$. 

2.2. **Disconnected reductive groups.** From now on we fix an algebraic group $G$ whose identity component $G^\circ$ is reductive. We set $A := G/G^\circ$ (a finite group). The canonical quotient morphism $G \to A$ will be denoted $\pi$.

Let $T$ be the “universal maximal torus” of $G^\circ$, i.e., the quotient $B/(B, B)$ for any Borel subgroup $B \subset G^\circ$. (Since all Borel subgroups in $G^\circ$ are $G^\circ$-conjugate, and since $B = N_{G^\circ}(B)$ acts trivially on $B/(B, B)$, the quotient $B/(B, B)$ does not depend on $B$, up to canonical isomorphism.) Let $X = X^*(T)$ be its weight lattice. If $T' \subset B$ is any maximal torus, then the composition $T' \to B \to T$ is an isomorphism, and this lets us identify $X$ with $X^*(T')$. The image in $X$ under this identification of the roots of $(G, T')$, and of the subset of positive roots (chosen as the opposite of the $T'$-weights on the Lie algebra of $B$), do not depend on the choice of $T'$; so they define the canonical root system $\Phi \subset X$ and the subset $\Phi^+ \subset \Phi$ of positive roots.

Similar comments apply to coroots, so that we can define the dominant weights $X^+ \subset X$. We denote by $W$ the Weyl group of $T$. (This group is well defined because $N_B(T') = T'$ for a maximal torus $T'$ contained in a Borel subgroup $B$.)

Given a weight $\lambda \in X^+$, we denote by $$ L(\lambda), \quad \Delta(\lambda), \quad \nabla(\lambda) $$

the irreducible, Weyl, and dual Weyl $G^\circ$-modules, respectively, corresponding to $\lambda$. Here $\nabla(\lambda)$ is defined as the induced module $\text{Ind}_{G^\circ}^G(k_B(\lambda))$ for some choice of Borel subgroup $B \subset G^\circ$, $L(\lambda)$ is the unique simple submodule of $\nabla(\lambda)$, and $\Delta(\lambda)$ is defined as $(\nabla(-w_0\lambda))^*$, where $w_0 \in W$ is the longest element. (These modules do not depend on the choice of $B$ up to isomorphism thanks to Lemma 2.1 and Lemma 2.3.)

For any $g \in G$ and any Borel subgroup $B \subset G^\circ$, $\text{ad}(g)$ induces an isomorphism $B/(B, B) \xrightarrow{\sim} gBg^{-1}/(gBg^{-1}, gBg^{-1})$. Since $gBg^{-1}$ is also a Borel subgroup of $G^\circ$, this defines an automorphism $\text{ad}(g)$ of $T$. The fact that $T$ is well defined translates to the property that $\text{ad}(g) = \text{id}$ if $g \in G^\circ$, so that $\text{ad}$ factors through a morphism $A \to \text{Aut}(T)$, which we will also denote by $\text{ad}$.

For $a \in A$ and $\lambda \in X$, we set $$ ^a\lambda := \lambda \circ \text{ad}(a^{-1}). $$

This operation defines an action of $A$ on $X$, which preserves $\Phi$, $\Phi^+$ and $X^+$. Moreover, Lemma 2.1 implies that for any $\lambda \in X^+$ and $g \in G$, we have canonical isomorphisms

$$ ^g\Delta(\lambda) \cong \Delta(\varpi(\lambda)), \quad ^gL(\lambda) \cong L(\varpi(\lambda)), \quad ^g\nabla(\lambda) \cong \nabla(\varpi(\lambda)). $$

We will denote by $\text{Irr}(G^\circ)$ the set of isomorphism classes of simple $G^\circ$-modules. This set admits an action of $G$, where $g$ acts via $[V] \mapsto [gV]$. (Of course, this action factors through an action of $A$.) The constructions above provide a natural bijection $X^+ \xrightarrow{\sim} \text{Irr}(G^\circ)$ (sending $\lambda$ to the isomorphism class of $L(\lambda)$), which is $A$-equivariant in view of (2.3).

**Lemma 2.4.** Let $V$ be an irreducible $G$-module. Then $V$ is semisimple as a $G^\circ$-module. All of its irreducible $G^\circ$-submodules lie in a single $G$-orbit in $\text{Irr}(G^\circ)$. 

Proof. Choose an irreducible $G^o$-submodule $M \subset V$, and choose a set of coset representatives $g_1, \ldots, g_r$ for $G^o$ in $G$. The subspace
$$\sum_{i=1}^r g_i M \subset V$$
is stable under the action of $G$, so it must be all of $V$. Each summand $g_i M$ is stable under $G^o$, so there is a surjective map of $G^o$-representations
$$\bigoplus_{i=1}^r g_i M \twoheadrightarrow \sum_{i=1}^r g_i M = V.$$Now, $g_i M$ is isomorphic as a $G^o$-module to $g_i M$; in particular, each $g_i M$ is an irreducible $G^o$-module, and $\bigoplus_i g_i M$ is semisimple. Thus, as a $G^o$-module, $V$ is a quotient of a semisimple module, all of whose summands lie in a single $G$-orbit of $\text{Irr}(G^o)$, so the same holds for $V$ itself. $\square$

2.3. The component group and induced representations. For each $a \in A = G/G^o$, let us choose, once and for all, a representative $\iota(a) \in G$. In the special case $a = 1_A$, we require that $\iota(1_A) = 1_G$.

Given $a, b \in A$, the representative $\iota(ab)$ need not be equal to $\iota(a)\iota(b)$; but these elements lie in the same coset of $G^o$. Explicitly, there is a unique element $\gamma(a, b) \in G^o$ such that
$$\iota(a)\iota(b) = \iota(ab)\gamma(a, b).$$Our assumption on $\iota(1_A)$ implies that for any $a \in A$, we have
$$\gamma(1_A, a) = \gamma(a, 1_A) = 1_G.$$By expanding $\iota(abc)$ in two ways, one finds that
$$\gamma(ab, c) \cdot \text{ad}(\iota(c)^{-1}) (\gamma(a, b)) = \gamma(a, bc)\gamma(b, c).$$Now let $V$ be a $G^o$-module. By Lemma 2.3, for any $a, b \in A$ the action of $\gamma(a, b)$ defines an isomorphism of $G^o$-modules
$$\gamma(a, b) V \cong V.$$Twisting by $\iota(ab)$ we deduce an isomorphism
$$\phi_{a, b} : \iota(a)\iota(b) V \cong \iota(ab) V.$$We can use the maps $\iota$ and $\gamma$ to explicitly describe representations of $G$ that are induced from $G^o$, as follows. Let us denote by $k[A]$ the group algebra of $A$ over $k$. Let $V$ be a $G^o$-module, and consider the vector space
$$\tilde{V} = k[A] \otimes V = \bigoplus_{f \in A} k f \otimes V.$$We now explain how to make $\tilde{V}$ into a $G$-module. Note that every element of $G$ can be written uniquely as $\iota(a)g$ for some $a \in A$ and $g \in G^o$. We put
$$\iota(a)g \cdot (f \otimes v) = af \otimes \gamma(a, f) \cdot \text{ad}(\iota(f)^{-1})(g) \cdot v.$$Using (2.4) one can check that this does indeed define an action of $G$ on $\tilde{V}$. 

Proof. Choose an irreducible $G^o$-submodule $M \subset V$, and choose a set of coset representatives $g_1, \ldots, g_r$ for $G^o$ in $G$. The subspace
$$\sum_{i=1}^r g_i M \subset V$$
is stable under the action of $G$, so it must be all of $V$. Each summand $g_i M$ is stable under $G^o$, so there is a surjective map of $G^o$-representations
$$\bigoplus_{i=1}^r g_i M \twoheadrightarrow \sum_{i=1}^r g_i M = V.$$Now, $g_i M$ is isomorphic as a $G^o$-module to $g_i M$; in particular, each $g_i M$ is an irreducible $G^o$-module, and $\bigoplus_i g_i M$ is semisimple. Thus, as a $G^o$-module, $V$ is a quotient of a semisimple module, all of whose summands lie in a single $G$-orbit of $\text{Irr}(G^o)$, so the same holds for $V$ itself. $\square$
Lemma 2.5. The map

\[ f \mapsto \sum_{a \in A} a \otimes f(\iota(a)) \]

defines an isomorphism of \( G \)-modules \( \text{Ind}_{G^o}^G(V) \overset{\sim}{\to} \tilde{V} \).

Proof. It is clear that our map is an isomorphism of vector spaces, and that its inverse sends \( a \otimes v \) to the function \( f : G \to V \) such that \( f(\iota(a)g) = g^{-1} \cdot v \) for \( g \in G^o \) and \( f(\iota(b)g) = 0 \) for \( g \in G^o \) and \( b \in A \setminus \{a\} \). It is not difficult to check that this inverse map respects the \( G \)-actions, proving the proposition. \( \square \)

In view of Lemma 2.5, it is clear that as \( G^o \)-modules, we have

\[ (2.7) \text{Ind}_{G^o}^G(V) \cong \bigoplus_{f \in A} \iota(f)V, \]

as expected.

2.4. A twisted group algebra of a stabilizer. Let \( \lambda \in X^+ \), and let \( A^\lambda = \{a \in A \mid {}^a\lambda = \lambda\} \) be its stabilizer. We also set \( G^\lambda := \omega^{-1}(A^\lambda) \). In view of (2.3), we have

\[ (2.8) G^\lambda = \{g \in G \mid {}^gL(\lambda) \cong L(\lambda)\}. \]

We fix a representative for the simple \( G^o \)-module \( L(\lambda) \) and, for each \( a \in A^\lambda \), an isomorphism of \( G^o \)-modules

\[ \theta_a : L(\lambda) \overset{\sim}{\to} \iota(a)L(\lambda). \]

In the special case that \( a = 1_A \), we require that

\[ \theta_{1_A} = \text{id}_{L(\lambda)}. \]

Explicitly, these maps have the property that for any \( g \in G^o \) and \( v \in L(\lambda) \), we have

\[ (2.9) \theta_a(g \cdot v) = \text{ad}(\iota(a)^{-1})(g) \cdot \theta_a(v), \]

where on the right-hand side we consider the given action of \( G^o \) on \( L(\lambda) \).

Now let \( a, b \in A^\lambda \), and consider the diagram

\[ \begin{array}{ccc}
L(\lambda) & \xrightarrow{\theta_a} & \iota(a)L(\lambda) \\
\downarrow{\theta_{ab}} & & \downarrow{\iota(a)\theta_b} \\
\iota(ab)L(\lambda) & \xrightarrow{\theta_{ab}} & \iota(ab)L(\lambda).
\end{array} \]

This is not a commutative diagram. Rather, both \( \theta_{ab} \) and \( \phi_{a,b} \circ \iota(a)\theta_b \circ \theta_a \) are isomorphisms of simple \( G^o \)-modules, so they must be scalar multiples of one another. Let \( \alpha(a,b) \in k^\times \) be the scalar such that

\[ \phi_{a,b} \iota(a)\theta_b \theta_a = \alpha(a,b) \cdot \theta_{ab}. \]

Our assumptions on \( \iota(1_A) \) and \( \theta_{1_a} \) imply that for all \( a \in A \), we have

\[ \alpha(1_A,a) = \alpha(a,1_A) = 1. \]

Given three elements \( a, b, c \in A^\lambda \), we can form the diagram shown in Figure 1. The subdiagram consisting of straight arrows is commutative (by (2.4), (2.9) and the definitions), whereas each curved arrow introduces a scalar factor. Comparing the different scalars shows that

\[ \alpha(a,b)\alpha(ab,c) = \alpha(a,bc)\alpha(b,c). \]
In other words, \( \alpha : A^\lambda \times A^\lambda \to k^\times \) is a 2-cocycle.

Let \( \mathcal{A}^\lambda \) be the twisted group algebra of \( A^\lambda \) determined by this cocycle. Explicitly, we define \( \mathcal{A}^\lambda \) to be the \( k \)-vector space spanned by symbols \( \{ \rho_a : a \in A^\lambda \} \) with multiplication given by

\[
\rho_a \rho_b = \alpha(a,b) \rho_{ab}.
\]

This is a unital \( k \)-algebra, with unit \( \rho_{1_A} \).

The algebra \( \mathcal{A}^\lambda \) can be described in more canonical terms as follows.

**Proposition 2.6.** There exists a canonical isomorphism of \( k \)-algebras

\[
\text{End}_{G^\lambda} \left( \text{Ind}_{G^\lambda}^G (L(\lambda)) \right) \cong (\mathcal{A}^\lambda)^{\text{op}}.
\]

**Proof.** We will work with the description of \( \text{Ind}_{G^\lambda}^G (L(\lambda)) \) from Lemma 2.5 (applied to the group \( G^\lambda \)): we identify it with \( k[A^\lambda] \otimes L(\lambda) \), where the action of \( G^\lambda \) is given by (2.6).

We begin by equipping \( k[A^\lambda] \otimes L(\lambda) \) with the structure of a right \( \mathcal{A}^\lambda \)-module as follows: given \( a, f \in A^\lambda \) and \( v \in L(\lambda) \), we put

\[
(f \otimes v) \cdot \rho_a := (fa) \otimes \gamma(f,a) \cdot \theta_a(v).
\]

Let us check that this is indeed a right \( \mathcal{A}^\lambda \)-module structure:

\[
((f \otimes v) \cdot \rho_a) \cdot \rho_b = ((fa) \otimes \gamma(f,a) \cdot \theta_a(v)) \cdot \rho_b
\]

\[
= (fab) \otimes \gamma(fa,b) \cdot \theta_b(\gamma(f,a) \cdot \theta_a(v))
\]

\[
= (fab) \otimes \gamma(f,ab) \gamma(a,b) \cdot \theta_b(\theta_a(v))
\]

\[
= (f \otimes v) \cdot (\alpha(a,b) \rho_{ab}).
\]
(Here, the third equality relies on (2.9), and the fourth one on (2.4).) Next, we check that the right action of $\mathfrak{A}^\lambda$ commutes with the left action of $G$:

$$
\iota(a)g \cdot ((f \otimes v) \cdot \rho_b) = \iota(a)g \cdot ((fb) \otimes \gamma(f, b) \cdot \theta_b(v))
$$

$$
= (a(fb) \otimes \gamma(a, fb) \text{ad}(\iota(fb)^{-1})(g)\gamma(f, b) \cdot \theta_b(v))
$$

$$
= (a(fb) \otimes \gamma(a, fb)\gamma(f, b)\text{ad}(\iota(fb)\gamma(f, b)^{-1})(g) \cdot \theta_b(v))
$$

$$
= (a(fb) \otimes \gamma(a, fb)\gamma(a, f)\text{ad}(\iota(f)^{-1})(g) \cdot \theta_b(v))
$$

$$
= ((a)f \otimes \gamma(a, f)\text{ad}(\iota(f)^{-1})(g) \cdot \theta_b(v))
$$

$$
= (a(f) \otimes \gamma(a, f)\text{ad}(\iota(f)^{-1})(g) \cdot \theta_b(v))
$$

As a consequence, the right $\mathfrak{A}^\lambda$-action gives rise to an algebra homomorphism

$$
\varphi : (\mathfrak{A}^\lambda)^\text{op} \to \text{End}_{G^\circ}(k[A^\lambda] \otimes L(\lambda)).
$$

For each $a \in A^\lambda$, the operator $\varphi(\rho_a)$ permutes the direct summands $kf \otimes L(\lambda) \subset k[A^\lambda] \otimes L(\lambda)$, as $f$ runs over elements of $A^\lambda$. Moreover, distinct $a$’s give rise to distinct permutations. It follows from this that the collection of linear operators $\{\varphi(\rho_a) : a \in A^\lambda\}$ is linearly independent. In other words, $\varphi$ is injective.

On the other hand, by adjunction, we have

$$
\dim \text{End}_{G^\circ}(\text{Ind}_{G^\circ}^G(L(\lambda))) = \dim \text{Hom}_{G^\circ}(\text{Ind}_{G^\circ}^G(L(\lambda)), L(\lambda)).
$$

Now, (2.7) implies that as a $G^\circ$-module, $\text{Ind}_{G^\circ}^G(L(\lambda))$ is isomorphic to a direct sum of $|A^\lambda|$ copies of $L(\lambda)$. So (2.11) shows that

$$
\dim \text{End}_{G^\circ}(\text{Ind}_{G^\circ}^G(L(\lambda))) = |A^\lambda| = \dim \mathfrak{A}^\lambda.
$$

Since $\varphi$ is an injective map between $k$-vector spaces of the same dimension, it is also surjective, and hence an isomorphism. □

**Remark 2.7.**

1. The $G^\circ$-module $L(\lambda)$ is defined only up to isomorphism. But if $L'(\lambda)$ is another choice for this module, then an isomorphism $L(\lambda) \xrightarrow{\sim} L'(\lambda)$ is unique up to scalar (and exists). Hence the induced isomorphism $\text{End}_{G^\circ}(\text{Ind}_{G^\circ}^G(L(\lambda))) \xrightarrow{\sim} \text{End}_{G^\circ}(\text{Ind}_{G^\circ}^G(L'(\lambda)))$ does not depend on the choice of isomorphism. In other words, the algebra $\text{End}_{G^\circ}(\text{Ind}_{G^\circ}^G(L(\lambda)))$ is completely canonical, i.e. does not depend on any choice.

2. Once the $G^\circ$-module $L(\lambda)$ is fixed, our description of the $k$-algebra $\mathfrak{A}^\lambda$, and of its identification with $\text{End}_{G^\circ}(\text{Ind}_{G^\circ}^G(L(\lambda)))^\text{op}$ in Proposition 2.6, depend on the choice of the isomorphisms $\theta_a$ for $a \in A \setminus \{1\}$. However, if $\{\theta'_a : a \in A \setminus \{1\}\}$ is another choice of such isomorphisms, then $\{\rho'_a : a \in A\}$ is the basis of the corresponding algebra $(\mathfrak{A}'^\lambda)^\lambda$, then for any $a \in A$ there exists a unique $t_a \in k^\times$ such that $\theta'_a = t_a\theta_a$. It is easy to check that the assignment $\rho'_a \mapsto t_a\rho_a$ defines an algebra isomorphism $(\mathfrak{A}'^\lambda)^\lambda \xrightarrow{\sim} \mathfrak{A}^\lambda$ which commutes with the identifications provided by Proposition 2.6.

3. If, instead of using Lemma 2.5 to describe the $G^\lambda$-module $\text{Ind}_{G^\circ}^G(L(\lambda))$, we describe it in terms of algebraic functions $\phi : G^\lambda \to L(\lambda)$ satisfying $\phi(gh) = h^{-1} \cdot \phi(g)$ for $h \in G^\circ$, then the right action of $\mathfrak{A}^\lambda$ on this module satisfies $(\phi \cdot \rho_a)(g) = \theta_a \circ \phi(g)(a)^{-1}$. 

2.5. Simple $G^\lambda$-modules whose restriction to $G^\circ$ is a direct sum of copies of $L(\lambda)$. We continue with the setting of §2.4, and in particular with our fixed $\lambda \in X^+$. If $E$ is a finite-dimensional left $\mathcal{A}^\lambda$-module, we define a $G^\lambda$-action on the $k$-vector space $E \otimes L(\lambda)$ by

$$
(2.12) \quad \iota(a)g \cdot (u \otimes v) = \rho_a u \otimes \theta_a^{-1}(gv) \quad \text{for } a \in A^\lambda \text{ and } g \in G^\circ.
$$

**Lemma 2.8.** The rule $(2.12)$ defines a structure of $G^\lambda$-module on $E \otimes L(\lambda)$.

**Proof.** Note that

$$
\iota(a)g \cdot (u \otimes v) = \iota(a)(\iota(b)\text{ad}(\iota(b)^{-1}))(g)v = \iota(ab)(\gamma(a,b)\text{ad}(\iota(b)^{-1}))(g)v.
$$

We now have

$$
\iota(a)\iota(b)h = \iota(a)\iota(b)\text{ad}(\iota(b)^{-1})(g)v = \iota(ab)(\gamma(a,b)\text{ad}(\iota(b)^{-1}))(g)v.
$$

We continue with the setting of $\mathcal{A}^\lambda$-modules whose restriction to $G^\circ$ is a direct sum of copies of $L(\lambda)$, and if we set $E := \text{Hom}_{G^\circ}(L(\lambda), V)$, then $E$ has a natural structure of a left $\mathcal{A}^\lambda$-module, and there exists an isomorphism of $G^\lambda$-modules

$$
\eta_{\lambda,E} : E \otimes L(\lambda) \simto V.
$$

We define the $\mathcal{A}^\lambda$-action on $E$ by

$$
(\rho_a \cdot f)(x) = \iota(a) \cdot f(\theta_a(x))
$$

for $f \in E = \text{Hom}_{G^\circ}(L(\lambda), V)$ and $x \in L(\lambda)$. (We leave it to the reader to check that $\rho_a \cdot f$ is a morphism of $G^\circ$-modules.) To justify that this defines an $\mathcal{A}^\lambda$-module structure, we simply compute:

$$
(\rho_a \cdot (\rho_b \cdot f))(x) = \iota(a) \cdot (\rho_b \cdot f)(\theta_a(x))
\begin{align*}
&= \iota(a) \cdot \iota(b) \cdot f(\theta_b \circ \theta_a(x)) \\
&= \iota(ab) \cdot \gamma(a,b) \cdot f(\theta_b \circ \theta_a(x)) \\
&= \iota(ab) \cdot f(\gamma(a,b) \cdot \theta_b \circ \theta_a(x)) \\
&= \alpha(a,b) \cdot \iota(ab) \cdot f(\theta_{ab}(x)) \\
&= (\alpha(a,b) \rho_{ab} \cdot f)(x).
\end{align*}
$$

Now there exists a canonical isomorphism of $G^\circ$-modules

$$
\eta_{\lambda,E} : E \otimes L(\lambda) \cong \text{Hom}_{G^\circ}(L(\lambda), V) \otimes L(\lambda) \simto V,
$$
defined by $\eta_{\lambda,E}(f \otimes v) = f(v)$. Let us check that this morphism also commutes with the action of $\iota(A)$. By definition we have

$$
\iota(a) \cdot (f \otimes v) = (\rho_a \cdot f) \otimes \theta_a^{-1}(v) = \sigma(\iota(a)) \circ f \circ \theta_a \otimes \theta_a^{-1}(v),
$$
where $\sigma : G^\lambda \to GL(V)$ is the morphism defining the $G^\lambda$-action. Hence

$$\eta_{\lambda,E}(v(a) \cdot (f \otimes v)) = \sigma(a) \cdot f(v) = \eta_{\lambda,E}(f \otimes v),$$

proving that $\eta_{\lambda,E}$ is an isomorphism of $G^\lambda$-modules.

It is clear that the assignments

$$- \otimes L(\lambda) : E \mapsto E \otimes L(\lambda) \quad \text{and} \quad \text{Hom}_{G^\lambda}(L(\lambda), -) : V \mapsto \text{Hom}_{G^\lambda}(L(\lambda), V)$$

define functors from the category of finite-dimensional $\mathcal{A}^\lambda$-modules to the category of finite-dimensional $G^\lambda$-modules whose restriction to $G^\circ$ are isomorphic to a direct sum of copies of $L(\lambda)$, and from the category of finite-dimensional $G^\lambda$-modules whose restriction to $G^\circ$ are isomorphic to a direct sum of copies of $L(\lambda)$ to the category of finite-dimensional $\mathcal{A}^\lambda$-modules respectively. It is straightforward to construct an isomorphism of functors $\text{Hom}_{G^\circ}(L(\lambda), -) \circ (- \otimes L(\lambda)) \sim \text{id}$, as well as an isomorphism $(- \otimes L(\lambda)) \circ \text{Hom}_{G^\circ}(L(\lambda), -) \sim \text{id}$ defined by $\eta_{\lambda,-}$. Our functors are thus equivalences of categories, quasi-inverse to each other; hence they define bijections between the sets of isomorphism classes of simple objects in these categories. \hfill \square

**Remark 2.10.** As in Remark 2.7, it can be easily checked that the assignment $E \mapsto E \otimes L(\lambda)$ does not depend on the choice of the isomorphisms $\{\theta_a : a \in A\}$, in the sense that if $\{\theta'_a : a \in A\}$ is another choice of such isomorphisms, and if $\mathcal{A}^\lambda$ is the corresponding algebra, then the identification $\mathcal{A}^\lambda \sim \mathcal{A}^\lambda$ considered in Remark 2.7 defines a bijection between isomorphism classes of simple $\mathcal{A}^\lambda$-modules and $\mathcal{A}^\lambda$-modules, which commutes with the operations $- \otimes L(\lambda)$. Of course, these constructions do not depend on the choice of $L(\lambda)$ in its isomorphism class either.

2.6. **Induction from $G^\lambda$ to $G$.** We continue with the setting of §§2.4–2.5. If $E$ is a finite-dimensional $\mathcal{A}^\lambda$-module, we now consider the $G$-module

$$L(\lambda, E) := \text{Ind}_{G^\lambda}^G(E \otimes L(\lambda)).$$

**Lemma 2.11.** If $E$ is a simple $\mathcal{A}^\lambda$-module, then $L(\lambda, E)$ is a simple $G$-module.

**Proof.** Let $V \subset L(\lambda, E)$ be a simple $G$-submodule. For any simple $G^\circ$-module $L$, let $[V : L]_{G^\circ}$ denote the multiplicity of $L$ as a composition factor of $V$, regarded as a $G^\circ$-module. The image of the embedding $V \mapsto L(\lambda, E)$ under the isomorphism

$$\text{Hom}_G(V, L(\lambda, E)) = \text{Hom}_G(V, \text{Ind}_{G^\lambda}^G(E \otimes L(\lambda))) \cong \text{Hom}_{G^\lambda}(V, E \otimes L(\lambda))$$

given by Frobenius reciprocity provides a nonzero morphism of $G^\lambda$-modules $V \to E \otimes L(\lambda)$, which must be surjective since $E \otimes L(\lambda)$ is simple by Proposition 2.9. It follows that $[V : L(\lambda)]_{G^\circ} \geq \dim(E)$. Now, as in (2.7), if $g_1, \ldots, g_r$ are representatives in $G$ of the cosets in $G/G^\lambda$, then as $G^\circ$-modules we have

$$L(\lambda, E) = \text{Ind}_{G^\lambda}^G(E \otimes L(\lambda)) \cong \bigoplus_{i=1}^r \theta_i L(\lambda)^{\oplus \dim(E)}.$$

Since $V$ is stable under the $G$-action, we have $[V : L(\lambda)]_{G^\circ} = [V : \theta_i L(\lambda)]_{G^\circ}$ for all $i$ (see Lemma 2.3), and hence $[V : \theta_i L(\lambda)]_{G^\circ} \geq \dim(E)$ for all $i$. This implies that $\dim(V) \geq \dim(\text{Ind}_{G^\lambda}^G(E \otimes L(\lambda)))$, so in fact $V = \text{Ind}_{G^\lambda}^G(E \otimes L(\lambda))$, as desired. \hfill \square
2.7. Simple G-modules. We come back to the general setting of §2.2. (In particular, the dominant weight $\lambda$ is not fixed anymore.) We can now prove that the procedure explained in §§2.4–2.6 allows us to construct all simple $G$-modules (up to isomorphism).

Lemma 2.12. Let $V$ be a simple $G$-module. Then there exists $\lambda \in X^+$, a simple $\mathcal{A}^\lambda$-module $E$, and an isomorphism of $G$-modules

$$V \xrightarrow{\sim} L(\lambda, E).$$

Proof. Certainly there exists $\lambda \in X^+$ and a surjection of $G^\circ$-modules $V \twoheadrightarrow L(\lambda)$. By Frobenius reciprocity we deduce a nonzero (hence injective) morphism of $G$-modules $V \hookrightarrow \text{Ind}_{G^\circ}^G(L(\lambda))$. So to conclude, it suffices to prove that all composition factors of $\text{Ind}_{G^\circ}^G(L(\lambda))$ are of the form $L(\lambda, E)$ (with $E$ a simple $\mathcal{A}^\lambda$-module). However, we have

$$\text{Ind}_{G^\circ}^G(L(\lambda)) \cong \text{Ind}_{G^\circ}^G(\text{Ind}_G^G(L(\lambda))).$$

The restriction of $\text{Ind}_{G^\circ}^G(L(\lambda))$ to $G^\circ$ is a direct sum of copies of $L(\lambda)$ by (2.7) applied to $G^\circ$. Therefore, all of its composition factors are of the form $E \otimes L(\lambda)$ with $E$ a simple $\mathcal{A}^\lambda$-module by Proposition 2.9. Since the functor $\text{Ind}_{G^\circ}^G$ is exact (by Lemma 2.5, or by [Ja, Corollary I.5.13]) and sends simple $G^\circ$-modules of the form $E \otimes L(\lambda)$ to simple $G$-modules by Lemma 2.11, the claim follows. \hfill \square

2.8. Conjugation. It now remains to understand when two modules of the form $L(\lambda, E)$ are isomorphic. For this, we need to analyze the relation between this construction applied to a dominant weight, and to a twist of this dominant weight by an element of $A$.

So, let $\lambda \in X^+$, and $a \in A$. Then we have

$$A^\lambda = aA^\lambda a^{-1}, \quad G^\lambda = i(a)G^\lambda i(a)^{-1},$$

and we can choose as $L(\lambda)$ the module $i(a)L(\lambda)$, cf. (2.3).

Let us choose isomorphisms $\theta_b : L(\lambda) \xrightarrow{\sim} i(b)L(\lambda)$ for all $b \in A^\lambda$. Again for $b \in A^\lambda$, we can consider the isomorphism

$$\tilde{\theta}_{aba^{-1}} : L(a^\lambda) = i(a)L(\lambda) \xrightarrow{\theta_b} i(b)i(a)L(\lambda) = i(b)i(a)^{-1}(i(a)L(\lambda)) \quad \sim \quad i(a)i(b)i(a)^{-1}(L(a^\lambda)) \xrightarrow{i(aba^{-1})^{-1}i(a)i(b)i(a)^{-1}^{-1}^{-1}} i(a)\sim L(a^\lambda).$$

(Here, the last isomorphism means the action of $i(aba^{-1})^{-1}i(a)i(b)i(a)^{-1}$ on $L(a^\lambda)$, or in other words the action of $i(a)^{-1}i(aba^{-1})^{-1}i(a)i(b)$ on $L(\lambda)$.)

The following claim can be checked directly from the definitions.

Lemma 2.13. For any $b, c \in A^\lambda$, we have

$$\gamma(aca^{-1}, aba^{-1}) \circ \tilde{\theta}_{aba^{-1}} \circ \tilde{\theta}_{aca^{-1}} = \alpha(c, b) \cdot \tilde{\theta}_{aca^{-1}}$$

(where here $\gamma(aca^{-1}, aba^{-1})$ means the action of this element on $L(a^\lambda)$).

If $\mathcal{A}^\lambda$ and its basis $\{\rho_b : b \in A^\lambda\}$ are defined in terms of the isomorphisms $\{\theta_b : b \in A^\lambda\}$ and if $\mathcal{A}_G^\lambda$ and its basis $\{\tilde{\rho}_b : b \in A^\lambda\}$ are defined in terms of the isomorphisms $\{\tilde{\theta}_a : a \in A^\lambda\}$, then Lemma 2.13 allows us to compare the cocycles that arise in the definitions of $\mathcal{A}^\lambda$ and $\mathcal{A}_G^\lambda$. More precisely, this lemma shows that the assignment $\rho_b \mapsto \tilde{\rho}_{aba^{-1}}$ defines an algebra isomorphism $\xi^G_{\lambda} : \mathcal{A}^\lambda \xrightarrow{\sim} \mathcal{A}_G^\lambda$. 

The isomorphism $\xi^a_\lambda$ can be described more canonically as follows. Recall that Proposition 2.6 provides canonical identifications

$$(\varphi^\lambda)^{op} \simeq \mathrm{End}_{G^\lambda}(\mathrm{Ind}_{G^\mu}^{G^\lambda}(L(\lambda))), \quad (\varphi^\mu)^{op} \simeq \mathrm{End}_{G^\mu}(\mathrm{Ind}_{G^\lambda}^{G^\mu}(L(\lambda))).$$

One can check that under these identifications, the automorphism $\xi^a_\lambda$ is given by the isomorphism

$$\mathrm{End}_{G^\lambda}(\mathrm{Ind}_{G^\mu}^{G^\lambda}(L(\lambda))) = \mathrm{End}_{G^\mu}(\mathrm{Ind}_{G^\lambda}^{G^\mu}(L(\lambda)))$$

(where we use the notation of Remark 2.2).

The properties of these isomorphisms that we will need below are summarized in the following lemma.

**Lemma 2.14.** Let $\lambda \in X^+$. 

1. If $a, b \in A$, then we have $\xi^a_b = \xi^a_b \circ \xi^b_a$.
2. If $a \in A^\lambda$, then $\xi^a$ is an inner automorphism of $\varphi^\lambda$.

**Proof.** (1) To simplify notation, we set $\mu := ab\lambda$. Note that the simple $G^\mu$-modules of highest weight $\mu$ used in the definitions of $\xi^a_b$ and $\xi^a_b \circ \xi^b_a$ are different: for the former we use the module $L_1(\mu) := \iota(ab)L(\lambda)$, while for the latter we use the module $L_2(\mu) := \iota(a)\iota(b)L(\lambda)$. There exists a canonical isomorphism

$$(2.13) \quad L_1(\mu) \sim \sim L_2(\mu),$$

given by the action of $\gamma(a, b)^{-1}$ on $L(\lambda)$ (i.e. the inverse of the isomorphism denoted $\phi_{a,b}$ in §2.3).

Our algebras are all defined as endomorphisms of some induced module, which can be described in terms of functions with values in the vector space underlying the representation $L(\lambda)$. From this point of view, $\xi^a_b \circ \xi^b_a$ is conjugation by the isomorphism of vector spaces $\mathrm{Ind}_{G^\mu}^{G^\lambda}(L(\lambda)) \sim \mathrm{Ind}_{G^\mu}^{G^\lambda}(L_2(\mu))$ sending functions $G^\lambda \rightarrow L(\lambda)$ to functions $G^\mu \rightarrow L(\lambda)$ and given by $\phi \mapsto \phi(\iota(b)^{-1}\iota(a)^{-1}(-)\iota(a)\iota(b))$, while $\xi^a_b$ is conjugation by the isomorphism $\mathrm{Ind}_{G^\mu}^{G^\lambda}(L_1(\mu)) \sim \mathrm{Ind}_{G^\mu}^{G^\lambda}(L(\lambda))$ given by $\phi \mapsto \phi(\iota(ab)(-))\iota(ab)^{-1})$. Taking into account the isomorphism (2.13), we have to check that conjugation by the isomorphism given by

$$(2.14) \quad \phi \mapsto \gamma(a, b) \cdot \phi(\iota(b)^{-1}\iota(a)^{-1}(-)\iota(a)\iota(b))$$

(where $\gamma(a, b) \cdot (-)$ means the action of $\gamma(a, b) \in G^\mu$ on $L(\lambda)$) coincides with conjugation by the isomorphism given by

$$(2.15) \quad \phi \mapsto \phi(\iota(ab)(-))\iota(ab)^{-1}).$$

However, since $\gamma(a,b)$ belongs to $G^\mu$, the functions $\phi$ we consider satisfy

$$\gamma(a, b) \cdot \phi(\iota(b)^{-1}\iota(a)^{-1}(-)\iota(a)\iota(b)) = \phi(\iota(b)^{-1}\iota(a)^{-1}(-)\iota(a)\iota(b)\gamma(a, b)^{-1})$$

$$= \phi(\iota(b)^{-1}\iota(a)^{-1}(-)\iota(ab)) = \phi(\gamma(a, b)^{-1}\iota(ab)^{-1})(-)\iota(ab)).$$

Thus, the isomorphisms (2.14) and (2.15) do not coincide, but they differ only by the action of an element of $G^\lambda$ (which, in fact, even belongs to $G^\mu$) on $\mathrm{Ind}_{G^\mu}^{G^\lambda}(L(\lambda))$. Therefore, conjugation by either (2.14) or (2.15) induces the same isomorphism of algebras $\mathrm{End}_{G^\mu}(\mathrm{Ind}_{G^\mu}^{G^\lambda}(L(\lambda))) \sim \mathrm{End}_{G^\mu}(\mathrm{Ind}_{G^\mu}^{G^\lambda}(L(\lambda)))$.

(2) By the comments preceding the statement, $\xi^a_\lambda$ is conjugation by an isomorphism $\mathrm{Ind}_{G^\mu}^{G^\lambda}(L(\lambda)) \sim \mathrm{Ind}_{G^\mu}^{G^\lambda}(L(\lambda))$. If $a \in A^\lambda$ then this isomorphism defines an invertible element of $\varphi^\lambda$, so that $\xi^a_\lambda$ is indeed an inner automorphism. \qed
Given \( a \in A \) and \( \lambda \in X^+ \), the isomorphism \( \xi^a_\lambda \) defines a bijection between the set of isomorphism classes of simple \( \mathcal{A} \)-\( \lambda \)-modules and the set of isomorphism classes of simple \( \mathcal{A}^{\lambda} \)-modules. From Lemma 2.14(1) we see that this operation defines an action of the group \( A \) on the set of pairs \( (\lambda, E) \) where \( \lambda \in X^+ \) and \( E \) is a simple \( \mathcal{A} \)-\( \lambda \)-module. Moreover, it follows from Lemma 2.14(2) that the induced action of \( A^\lambda \) on the set of isomorphism classes of simple \( \mathcal{A}^{\lambda} \)-modules is trivial.

**Lemma 2.15.** Let \( \lambda \in X^+ \), and let \( E \) be a simple \( \mathcal{A}^{\lambda} \)-module. Let \( a \in A \), and let \( E' \) be the simple \( \mathcal{A}^{\lambda} \)-module deduced from \( E \) via the isomorphism \( \xi^a_\lambda : \mathcal{A}^{\lambda} \isom \mathcal{A}^{\lambda} \). Then there exists an isomorphism of \( G \)-modules

\[
L(\lambda, E) \isom L(a^\lambda, E').
\]

**Proof.** As above we choose for our simple \( G^\lambda \)-module of highest weight \( a^\lambda \) the module \( G^{\lambda} \). Then conjugation by \( a^\lambda \) induces an isomorphism \( G^{\lambda} \isom G^{\lambda} \), and using the notation of Remark 2.2 we have as \( G^{\lambda} \)-modules

\[
\xi^a(\mathcal{A}^{\lambda} \otimes L(\lambda)) = E' \otimes L(a^\lambda).
\]

In view of Lemma 2.1 we deduce an isomorphism of \( G \)-modules

\[
\xi^a(\text{Ind}_{G^{\lambda}}^{G}(E \otimes L(\lambda))) \isom \text{Ind}_{G^{a\lambda}}^{G}(E' \otimes L(a^\lambda)).
\]

Now by Lemma 2.3 the left-hand side is isomorphic to \( L(\lambda, E) \), and the claim follows. \( \square \)

2.9. **Classification of simple \( G \)-modules.** We denote by \( \text{Irr}(G) \) the set of isomorphism classes of simple \( G \)-modules. Now we can finally state the main result of this section.

**Theorem 2.16.** The assignment \( (\lambda, E) \mapsto L(\lambda, E) \) induces a bijection

\[
\left\{ (\lambda, E) \mid \lambda \in X^+ \text{ and } E \text{ an isom. class of simple left } \mathcal{A}^{\lambda} \text{-modules} \right\} / A \leftrightarrow \text{Irr}(G).
\]

**Proof.** From Lemma 2.11, we see that the assignment \( (\lambda, E) \mapsto L(\lambda, E) \) defines a map from the set of pairs \( (\lambda, E) \) as in the statement to the set \( \text{Irr}(G) \). By Lemma 2.15 this map factors through a map

\[
\left\{ (\lambda, E) \mid \lambda \in X^+ \text{ and } E \text{ an isom. class of simple left } \mathcal{A}^{\lambda} \text{-modules} \right\} / A \rightarrow \text{Irr}(G).
\]

By Lemma 2.12, this latter map is surjective. Hence, all that remains is to prove that it is injective.

Let \( (\lambda, E) \) and \( (\lambda', E') \) be pairs as above. Let \( V = L(\lambda, E) \) and \( V' = L(\lambda', E') \), and assume that \( V \cong V' \). As a \( G^\lambda \)-representation, \( V \) is isomorphic to a direct sum of twists of \( L(\lambda) \), and \( V' \) is isomorphic to a direct sum of twists of \( L(\lambda') \) (see the proof of Lemma 2.11). Hence \( L(\lambda) \) and \( L(\lambda') \) are twists of each other, which implies that \( \lambda \) and \( \lambda' \) are in the same \( A \)-orbit. Therefore, we can (and shall) assume that \( \lambda = \lambda' \). Fix some isomorphism \( \phi : V \isom V' \), and consider the morphism of \( G^{\lambda} \)-modules \( f : V \rightarrow E' \otimes L(\lambda) \) deduced by Frobenius reciprocity. If \( g_1, \ldots, g_r \) are representatives of the cosets in \( G/G^{\lambda} \), with \( g_1 = 1_G \), then we have an isomorphism of \( G^\lambda \)-modules

\[
\text{Ind}_{G^{\lambda}}^{G}(E \otimes L(\lambda)) \cong \bigoplus_{i=1}^{r} g_i L(\lambda) \otimes E.
\]
If \( i \neq 1 \), then \( \pi(L(\lambda)) \) is not isomorphic to \( L(\lambda) \). Hence \( f \) is zero on the corresponding summand of \( \text{Ind}^G_{G_0}(E \otimes L(\lambda)) \). We deduce that the composition
\[
E \otimes L(\lambda) \hookrightarrow \text{Ind}^G_{G_0}(E \otimes L(\lambda)) \xrightarrow{f} E' \otimes L(\lambda),
\]
where the first morphism is again deduced from Frobenius reciprocity, is nonzero. But this morphism is a morphism of \( G^\lambda \)-modules. Since \( L(\lambda, E) \) and \( L(\lambda, E') \) are simple, it must be an isomorphism, and by Proposition 2.9 this implies that \( E \cong E' \) as \( \mathcal{A}^\lambda \)-modules.

**Remark 2.17.** (1) As explained above Lemma 2.15, for any \( \lambda \in X^+ \) the action of \( A^\lambda \) on the set of isomorphism classes of irreducible \( \mathcal{A}^\lambda \)-modules is trivial. Hence if \( \Lambda \subset X^+ \) is a set of representatives of the \( A \)-orbits in \( X^+ \), the quotient considered in the statement of Theorem 2.16 can be described more explicitly as the set of pairs \( (\lambda, E) \) where \( \lambda \in \Lambda \) and \( E \) is an isomorphism class of simple \( \mathcal{A}^\lambda \)-modules.

(2) Assume that \( \iota \) is a group morphism (so that \( G \) is isomorphic to the semi-direct product \( A \ltimes G^\circ \)) and that moreover there exists a Borel subgroup \( B \subset G^\circ \) such that \( \iota(a)B\iota(a)^{-1} = B \) for any \( a \in A \). Then if we define the standard and costandard \( G^\circ \)-modules using this Borel subgroup, the isomorphisms
\[
\iota(a)\Delta(\lambda) \cong \Delta(a\lambda), \quad \iota(a)\nabla(\lambda) \cong \nabla(a\lambda)
\]
(see (2.3)) can be chosen in a canonical way. In fact, our assumptions imply that there exist unique \( B \)-stable lines in \( \iota(a)\Delta(\lambda) \) and \( \Delta(a\lambda) \), and moreover that these lines coincide. Hence there exists a unique isomorphism of \( G \)-modules \( \iota(a)\Delta(\lambda) \iso \Delta(a\lambda) \) which restricts to the identity on these \( B \)-stable lines. Similar comments apply to \( \iota(a)\nabla(\lambda) \) and \( \nabla(a\lambda) \).

In particular, the isomorphisms \( \theta_a \) of §2.4 can be chosen in a canonical way. Then the cocycle \( \alpha \) will be trivial, so that in this case \( \mathcal{A}^\lambda \) is canonically isomorphic to the group algebra \( k[A^\lambda] \).

### 2.10. Semisimplicity

We finish this section with a criterion ensuring that the algebra \( \mathcal{A}^\lambda \) is semisimple unless \( p \) is small.

**Lemma 2.18.** Assume that \( p \nmid |A| \). If \( V \) is a simple \( G^\circ \)-module, then \( \text{Ind}^G_{G_0}(V) \) is a semisimple \( G \)-module.

**Proof.** Let \( M \) be a \( G \)-submodule of \( \text{Ind}^G_{G_0}(V) \), and let \( N = \text{Ind}^G_{G_0}(V)/M \). We will show that the image \( c \) of the exact sequence \( M \hookrightarrow \text{Ind}^G_{G_0}(V) \twoheadrightarrow N \) in \( \text{Ext}^1_G(N, M) \) vanishes.

First we remark that for any two algebraic \( G \)-modules \( X, Y \), the forgetful functor from \( \text{Rep}(G) \) to \( \text{Rep}(G^\circ) \) induces an isomorphism
\[
\text{Hom}_G(X, Y) \iso (\text{Hom}_{G^\circ}(X, Y))^A.
\]
Under our assumptions the functor \((-)^A \) is exact. On the other hand, it is easily checked that the restriction of any injective \( G \)-module to \( G^\circ \) is injective. Hence this isomorphism induces an isomorphism
\[
\text{Ext}^n_G(X, Y) \iso (\text{Ext}^n_{G^\circ}(X, Y))^A.
\]
for any $n \geq 0$. We deduce in particular that the forgetful functor induces an injection

$$\text{Ext}^1_G(N, M) \hookrightarrow \text{Ext}^1_{G^x}(N, M).$$

Hence to prove that $c = 0$ it suffices to prove that the sequence $M \hookrightarrow \text{Ind}_{G^x}^G(V) \twoheadrightarrow N$, considered as an exact sequence of $G^o$-modules, splits. This fact is clear since $\text{Ind}_{G^x}^G(V)$ is semisimple as a $G^o$-module, see (2.7).

From this lemma (applied to the group $A^\lambda$) and Proposition 2.6 we deduce the following.

**Lemma 2.19.** If $p \nmid |A^\lambda|$, then the algebra $A^\lambda$ is semisimple (and in fact isomorphic to a product of matrix algebras).

### 3. Highest weight structure

Our goal in this section is to prove that if $p \nmid |A|$, then the category $\text{Rep}(G)$ of finite-dimensional $G$-modules admits a natural structure of a highest weight category.

For the beginning of the section, we continue with the setting of §2.2 (not imposing any further assumption).

#### 3.1. The order

If $(\lambda, E)$ is a pair as in Theorem 2.16, we denote by $[\lambda, E]$ the corresponding $A$-orbit. We define a relation $<$ on the set of such orbits as follows:

$$(3.1) \quad [\lambda, E] < [\lambda', E'] \quad \text{if and only if} \quad \text{for some } a \in A, \text{ we have } a\lambda < \lambda'.$$

(Here, the order on $X$ is the standard one, where $\lambda \leq \mu$ iff $\mu - \lambda$ is a sum of positive roots.)

**Lemma 3.1.** The relation $<$ is a partial order.

**Proof.** Using the fact that for $a \in A$ and $\lambda, \mu \in X$ such that $\lambda \leq \mu$ we have $a\lambda \leq a\mu$ (because the $A$-action is linear and preserves positive roots), one can easily check that this relation is transitive. What remains to be seen is that there cannot exist classes $[\lambda, E], [\lambda', E']$ such that

$$[\lambda, E] < [\lambda', E'] < [\lambda, E].$$

However, in this case we have $a\lambda < \lambda$ for some $a \in A$. Since $a$ permutes the positive coroots of $G^o$, then if we denote by $2\rho^\vee$ the sum of these coroots we must have $\langle a\lambda, 2\rho^\vee \rangle = \langle \lambda, 2\rho^\vee \rangle$, hence $\langle \lambda - a\lambda, 2\rho^\vee \rangle = 0$. On the other hand, by assumption $\lambda - a\lambda$ is a nonzero sum of positive roots, so that its pairing with $2\rho^\vee$ cannot vanish. This provides the desired contradiction. \hfill \Box

#### 3.2. Standard $G$-modules

Let $\lambda \in X^+$. We will work in the setting of §§2.3–2.4, including, in particular, fixing a $G^2$-module $L(\lambda)$, and notation such as $\iota$, $\gamma$, $\theta$, and $\alpha$. We also fix a representative $\Delta(\lambda)$ for the Weyl module surjecting to $L(\lambda)$, and a surjection $\pi^\lambda : \Delta(\lambda) \to L(\lambda)$.

Since $\text{End}_{G^2}(\Delta(\lambda)) = k \cdot \text{id}$, from (2.3) we see that for each $a \in A^\lambda$, there exists a unique isomorphism $\theta_a^\lambda : \Delta(\lambda) \cong (\iota(a)\Delta(\lambda))$ such that the following diagram
commutes:
\[
\Delta(\lambda) \xrightarrow{\theta_a^\lambda} \iota(a)\Delta(\lambda) \\
\Downarrow \\
L(\lambda) \xrightarrow{\theta_a} \iota(a)L(\lambda).
\]
Moreover, this uniqueness implies that for any \(a, b \in A^\lambda\), if we define \(\phi_{a,b}^\Delta : \Delta(\lambda) \to \Delta(\lambda)\) as the action of \(\gamma(a, b)\), then we have
\[
(3.2) \quad \phi_{a,b}^\Delta \theta_a^\lambda \theta_b^\lambda = \alpha(a, b)\theta_{ab}^\lambda.
\]

Remark 3.2. These considerations show that the subgroup \(A^\lambda \subset A\) can be equivalently defined as consisting of the elements \(a \in A\) such that \(\iota(a)\Delta(\lambda) \cong \Delta(\lambda)\). The twisted group algebra \(\mathcal{A}^\lambda\) can also be defined in terms of a choice of isomorphisms \((\theta_a^\lambda : a \in A^\lambda)\) instead of isomorphisms \((\theta_a : a \in A^\lambda)\).

Lemma 3.3. Let \(E\) be a simple left \(\mathcal{A}^\lambda\)-module. The following rule defines the structure of a \(G^\lambda\)-module on the vector space \(E \otimes \Delta(\lambda)\):
\[
\iota(a)g \cdot (u \otimes v) = \rho_a u \otimes (\theta_a^\lambda)^{-1}(gv) \quad \text{for any } a \in A^\lambda \text{ and } g \in G^\circ.
\]
This \(G^\lambda\)-module has \(E \otimes L(\lambda)\) as its unique irreducible quotient. Moreover, all the \(G^\circ\)-composition factors of the kernel of the quotient map \(E \otimes \Delta(\lambda) \to E \otimes L(\lambda)\) are of the form \(L(\mu)\) with \(\mu < \lambda\).

Proof. We begin by noting that thanks to (3.2), the calculation from Lemma 2.8 can be repeated to show that the formula above does, indeed, define the structure of a \(G^\lambda\)-module on \(E \otimes \Delta(\lambda)\). Moreover, the quotient map \(\pi^\lambda : \Delta(\lambda) \to L(\lambda)\) induces a surjective map of \(G^\lambda\)-modules
\[
\pi^\lambda_R := \text{id}_E \otimes \pi : E \otimes \Delta(\lambda) \to E \otimes L(\lambda).
\]
If we forget the \(G^\lambda\)-module structure and regard \(E \otimes \Delta(\lambda)\) as just a \(G^\circ\)-module, then it is clear that its unique maximal semisimple quotient can be identified with \(E \otimes L(\lambda)\), and that the highest weights of the kernel of \(\pi^\lambda_R\) are \(< \lambda\). Now, let \(M\) be the head of \(E \otimes \Delta(\lambda)\) as a \(G^\lambda\)-module. Since \(M\) must remain semisimple as a \(G^\circ\)-module (by Lemma 2.4), it cannot be larger than \(E \otimes L(\lambda)\). In other words, \(E \otimes L(\lambda)\) is the unique simple quotient of \(E \otimes \Delta(\lambda)\).

Proposition 3.4. Let \(E\) be a simple \(\mathcal{A}^\lambda\)-module. The \(G\)-module
\[
\Delta(\lambda, E) := \text{Ind}_{G^\circ}^{G^\lambda}(E \otimes \Delta(\lambda))
\]
admits \(L(\lambda, E)\) as its unique irreducible quotient. Moreover, all the composition factors of the kernel of the quotient map \(\Delta(\lambda, E) \to L(\lambda, E)\) are of the form \(L(\mu, E')\) with \([\mu, E'] < [\lambda, E]\).

Proof. The surjection \(E \otimes \Delta(\lambda) \to E \otimes L(\lambda)\) from Lemma 3.3 induces a surjection \(\Delta(\lambda, E) \to L(\lambda, E)\) since the functor \(\text{Ind}_{G^\circ}^{G^\lambda}\) is exact (see the proof of Lemma 2.12). If \(g_1, \ldots, g_r\) are representatives of the cosets in \(G/G^\lambda\), then as \(G^\circ\)-modules we have
\[
(3.3) \quad \Delta(\lambda, E) \cong \bigoplus_{i=1}^r E \otimes g_i \Delta(\lambda), \quad L(\lambda, E) \cong \bigoplus_{i=1}^r E \otimes g_i L(\lambda).
\]
Therefore, as in the proof of Lemma 2.12, \(L(\lambda, E)\) is the head of \(\Delta(\lambda, E)\) as a \(G^\circ\)-module, hence also as a \(G\)-module.
If \( L(\mu, E') \) is a \( G \)-composition factor of the kernel of the surjection \( \Delta(\lambda, E) \rightarrow L(\lambda, E) \), then some twist of \( L(\mu) \) must be a \( G^\circ \)-composition factor of the surjection \( g^i \Delta(\lambda) \rightarrow g^i L(\lambda) \) for some \( i \). Therefore \( \mu \) is smaller than some twist of \( \lambda \), and we deduce that \( [\mu, E'] < [\lambda, E] \).

3.3. Ext\(^1\)-vanishing. The same proof as for Lemma 2.15 shows that, up to isomorphism, \( \Delta(\lambda, E) \) only depends on the orbit \([\lambda, E]\). The following lemma shows that this module is a “partial projective cover” of \( L(\lambda, E) \) (under the assumption that \( p \nmid |A| \)).

**Lemma 3.5.** Assume that \( p \nmid |A| \). For any two pairs \((\lambda, E)\) and \((\mu, E')\), we have

\[
\text{Ext}_G^1(\Delta(\lambda, E), L(\mu, E')) \neq 0 \implies [\mu, E'] > [\lambda, E].
\]

**Proof.** As in the proof of Lemma 2.18, we have a canonical isomorphism

\[
\text{Ext}_G^1(\Delta(\lambda, E), L(\mu, E')) \cong \left( \text{Ext}_{G^\circ}^1(\Delta(\lambda, E), L(\mu, E')) \right)^A.
\]

If we assume that \( \text{Ext}_G^1(\Delta(\lambda, E), L(\mu, E')) \neq 0 \), then this isomorphism shows that we must also have \( \text{Ext}_{G^\circ}^1(\Delta(\lambda, E), L(\mu, E')) \neq 0 \). Using (3.3), we deduce that for some \( g, h \in G \) we have

\[
\text{Ext}_{G^\circ}^1(g\Delta(\lambda), hL(\mu)) \neq 0.
\]

This implies that \( \varpi(h) \mu > \varpi(g) \lambda \), hence that \( [\mu, E'] > [\lambda, E] \). \( \square \)

3.4. Costandard \( G \)-modules. Fix again \( \lambda \in X^+ \) and a simple \( \mathcal{A}^\lambda \)-module \( E \). Then after fixing a costandard module \( \nabla(\lambda) \) with socle \( L(\lambda) \) and an embedding \( L(\lambda) \hookrightarrow \nabla(\lambda) \), as in §3.2 the isomorphisms \( \theta_a \) can be “lifted” to isomorphisms \( \theta_a^\nabla : \nabla(\lambda) \cong (\circ)\nabla(\lambda) \), which satisfy the appropriate analogue of (3.2). Using these isomorphisms one can define a \( G^\lambda \)-module structure on \( E \otimes \nabla(\lambda) \) by the same procedure as in Lemma 3.3. Then the same arguments as for Proposition 3.4 show that \( \nabla(\lambda, E) := \text{Ind}_{G^\circ}^G(E \otimes \nabla(\lambda)) \) admits \( L(\lambda, E) \) as its unique simple submodule, and that all the composition factors of the injection \( L(\lambda, E) \hookrightarrow \nabla(\lambda, E) \) are of the form \( L(\mu, E') \) with \( [\mu, E'] < [\lambda, E] \). Moreover, as in Lemma 3.5, if \( p \nmid |A| \) we have

\[
\text{Ext}_G^1(L(\mu, E'), \nabla(\lambda, E)) \neq 0 \implies [\mu, E'] > [\lambda, E].
\]

**Lemma 3.6.** Assume that \( p \nmid |A| \), and let \((\lambda, E)\) and \((\mu, E')\) be pairs as above. Then for any \( i > 0 \) we have

\[
\text{Ext}_G^i(\Delta(\lambda, E), \nabla(\mu, E')) = 0.
\]

Moreover

\[
\text{Hom}_G(\Delta(\lambda, E), \nabla(\mu, E')) = 0
\]

unless \([\lambda, E] = [\mu, E']\), in which case this space is 1-dimensional.

**Proof.** As in the proof of Lemma 2.18, for any \( i > 0 \) we have

\[
\text{Ext}_G^i(\Delta(\lambda, E), \nabla(\mu, E')) \cong \left( \text{Ext}_{G^\circ}^i(\Delta(\lambda, E), \nabla(\mu, E')) \right)^A.
\]

As \( G^\circ \)-modules \( \Delta(\lambda, E) \) is isomorphic to a direct sum of Weyl modules, and \( \nabla(\mu, E') \) is isomorphic to a direct sum of induced modules. Hence, the right-hand side vanishes unless \( i = 0 \), which proves the first claim.

For the second claim we remark that if \( \text{Hom}_G(\Delta(\lambda, E), \nabla(\mu, E')) \neq 0 \), then \( L(\lambda, E) \) is a composition factor of \( \nabla(\mu, E') \), so that \([\lambda, E] \leq [\mu, E']\), and \( L(\mu, E') \) is a composition factor of \( \Delta(\lambda, E) \), so that \([\mu, E'] \leq [\lambda, E] \). We deduce that \([\mu, E'] =
Moreover, in this case any nonzero morphism in this space must be a multiple of the composition
\[ \Delta(\lambda, E) \rightarrow L(\lambda, E) \hookrightarrow \nabla(\lambda, E), \]
which concludes the proof. \( \square \)

3.5. Highest weight structure. Let \( \mathcal{C} \) be a finite-length \( k \)-linear abelian category such that \( \text{Hom}_\mathcal{C}(M, N) \) is finite-dimensional for any \( M, N \) in \( \mathcal{C} \). Let \( \mathcal{I} \) be the set of isomorphism classes of irreducible objects of \( \mathcal{C} \). Assume that \( \mathcal{I} \) is equipped with a partial order \( \leq \), and that for each \( s \in \mathcal{I} \) we have a fixed representative of the simple object \( L_s \). Assume also we are given, for any \( s \in \mathcal{I} \), objects \( \Delta_s \) and \( \nabla_s \), and morphisms \( \Delta_s \rightarrow L_s \) and \( L_s \rightarrow \nabla_s \). For \( \mathcal{I} \subset \mathcal{I} \), we denote by \( \mathcal{C}_\mathcal{I} \) the Serre subcategory of \( \mathcal{C} \) generated by the objects \( L_t \) for \( t \in \mathcal{I} \). We write \( \mathcal{C} \leq s \) for \( \mathcal{C} \{ t \in \mathcal{I} | t \leq s \} \), and similarly for \( \mathcal{C} < s \).

Recall that the category \( \mathcal{C} \) (together with the above data) is said to be a highest weight category if the following conditions hold:

1. for any \( s \in \mathcal{I} \), the set \( \{ t \in \mathcal{I} | t \leq s \} \) is finite;
2. for each \( s \in \mathcal{I} \), we have \( \text{End}_\mathcal{C}(L_s) = k \);
3. for any \( s \in \mathcal{I} \) and any ideal \( \mathcal{I} \subset \mathcal{I} \) such that \( s \in \mathcal{I} \) is maximal, \( \Delta_s \rightarrow L_s \) is a projective cover in \( \mathcal{C}_\mathcal{I} \) and \( L_s \rightarrow \nabla_s \) is an injective envelope in \( \mathcal{C}_\mathcal{I} \);
4. the kernel of \( \Delta_s \rightarrow L_s \) and the cokernel of \( L_s \rightarrow \nabla_s \) belong to \( \mathcal{C}_{<s} \);
5. we have \( \text{Ext}^2_{\mathcal{C}}(\Delta_s, \nabla_t) = 0 \) for all \( s, t \in \mathcal{I} \).

In this case, the poset \( (\mathcal{I}, \leq) \) is called the weight poset of \( \mathcal{C} \).

See [Ri, §7] for the basic properties of highest weight categories (following Cline–Parshall–Scott and Be˘ılinson–Ginzburg–Soergel).

We can finally state the main result of this section.

**Theorem 3.7.** Assume that \( p \nmid |A| \). The category \( \text{Rep}(G) \), equipped with the poset
\[ \{ (\lambda, E) \mid \lambda \in X^+ \text{ and } E \text{ an isom. class of simple } \mathfrak{g}^\lambda \text{-modules} \} / A \]
(with the order defined in (3.1)) and the objects \( \Delta(\lambda, E), L(\lambda, E), \nabla(\lambda, E) \), is a highest weight category.

**Proof.** The desired properties are verified in Theorem 2.16, Proposition 3.4 and Lemma 3.5, their variants for costandard objects (see §3.4), and Lemma 3.6. \( \square \)

4. Grothendieck groups

Our goal in this section is to prove a generalization of a result of Serre [Se] providing a description of the Grothendieck group of any split connected reductive group over a complete discrete valuation ring. (In [Se], the author considers more general coefficients, but we will restrict to the setting we need for the application in [AHR].)

4.1. Setting. We will denote by \( \mathcal{O} \) a complete discrete valuation ring, with algebraically closed residue field \( \mathcal{F} \). We also denote by \( \mathcal{K} \) the fraction field of \( \mathcal{O} \), and by \( \mathcal{K} \) an algebraic closure of \( \mathcal{K} \). We will assume that \( \mathcal{K} \) has characteristic 0, and that \( \mathcal{F} \) has characteristic \( p > 0 \).
We will consider an affine $\mathcal{O}$-group scheme $G$, a closed normal subgroup $G^0 \subset G$, and we will denote by $A$ the factor group of $G$ by $G^0$ in the sense of [Ja, §I.6.1] (i.e. of [DG, III, §3, n. 3]). We will make the following assumptions:

(1) $G^0$ is a reductive group scheme over $\mathcal{O}$ (in the sense of [SGA3.3]);

(2) $A$ is the constant group scheme associated with a finite group $A$, and moreover $\text{char}(F)$ does not divide $|A|$.

We will now note a few consequences of these assumptions. We begin with the following observation.

**Lemma 4.1.** Any reductive group scheme over $\mathcal{O}$ (in particular, $G^0$) is split.

**Proof.** This result follows from the arguments in the proof of [McN, Corollary 2.1.2]. Namely, let $H$ be a reductive group scheme over $\mathcal{O}$, and let $K$ be a split $\mathcal{O}$-torus such that there exists a closed embedding $\text{Spec}(\mathbb{F}) \times_{\text{Spec}(\mathcal{O})} K \to \text{Spec}(\mathbb{F}) \times_{\text{Spec}(\mathcal{O})} H$. By [SGA3.2, Exp. XI, Corollaire 4.2] and [EGA4.4, Théorème 18.5.17], there exists an $\mathcal{O}$-group scheme morphism $f : K \to H$ which lifts this embedding. If we let $K$ act on itself by left multiplication, and on $H$ by left multiplication via $f$, then $f$ is $K$-equivariant. Hence so is the induced morphism

\[ \mathcal{O}(H) \to \mathcal{O}(K). \]

In other words (see [Ja, §I.2.11]), both $\mathcal{O}(H)$ and $\mathcal{O}(K)$ admit gradings by characters of $K$, and (4.1) is a graded morphism. Now each graded piece of $\mathcal{O}(K)$ has finite rank over $\mathcal{O}$ (in fact, these pieces are free of rank 1), and the image of this morphism under the functor $\mathbb{F} \otimes_{\mathcal{O}} -$ is surjective by the construction of $f$. By the Nakayama lemma, we deduce that (4.1) itself is surjective, i.e. that $f$ is a closed embedding.

Finally, it follows from [SGA3.3, Exp. XIX, Théorème 2.5] that the rank of the $\mathbb{K}$-group $\text{Spec}(\mathbb{K}) \times_{\text{Spec}(\mathcal{O})} H$ coincides with that of $\text{Spec}(\mathbb{F}) \times_{\text{Spec}(\mathcal{O})} H$, so that $\text{Spec}(\mathbb{K}) \times_{\text{Spec}(\mathcal{O})} K$ is a maximal torus in $\text{Spec}(\mathbb{K}) \times_{\text{Spec}(\mathcal{O})} H$. We have thus proved that $K$ is a maximal torus in $H$, and hence that the latter group is split. \hfill $\square$

Next, from [Ja, §I.5.7] (or from [DG, III, §3, Proposition 2.5]) we deduce that the quotient morphism $\varpi : G \to A$ is flat, and hence that $G$ is a flat $\mathcal{O}$-group scheme (since $A$ is flat by assumption). If $k$ is one of $F$, $K$ or $\mathbb{K}$, we set

\[ G_k := \text{Spec}(k) \times_{\text{Spec}(\mathcal{O})} G, \quad G^0_k := \text{Spec}(k) \times_{\text{Spec}(\mathcal{O})} G^0. \]

Then $G_k$ is an extension of the constant (hence smooth) $k$-group scheme associated with $A$ by the smooth group scheme $G^0_k$, so it is smooth by [Mi, Proposition 8.1]. From this we deduce that $G$ itself is smooth (see [SP, Tag 01V8]).

In particular, the groups $G_\mathbb{F}$ and $G_\mathbb{K}$ are algebraic groups (over $\mathbb{F}$ and $\mathbb{K}$) in the usual “naive” sense. Since $G^0_\mathbb{F}$ is connected and $A$ is finite, the latter group identifies with the group of components of $G_\mathbb{F}$. Similarly, $A$ also identifies with the group of components of $G_\mathbb{K}$.

**Lemma 4.2.** The morphism $G(\mathcal{O}) \to A$ induced by $\varpi$ is surjective.

**Proof.** We consider the commutative diagram

\[ \begin{array}{ccc}
G(\mathcal{O}) & \longrightarrow & A(\mathcal{O}) \\
\downarrow & & \downarrow \\
G(\mathbb{F}) & \longrightarrow & A(\mathbb{F})
\end{array} \]
where the horizontal maps are induced by $\varpi$ and the vertical ones by the quotient morphism $\mathcal{O} \to \mathbb{F}$. Here the lower arrow is surjective, and the right vertical arrow is an isomorphism. On the other hand the left vertical arrow is surjective by [EGA4.4, Théorème 18.5.17]. We deduce that the upper arrow is surjective, as desired. □

Thanks to Lemma 4.2, we can (and will) choose a section $\iota : A \to G(\mathcal{O})$ of the projection induced by $\varpi$. (Of course, we do not assume that $\iota$ is a group morphism.) We will assume that $\iota(1) = 1$. For simplicity, we will also denote by $\iota : A \to G$ the morphism of $\mathcal{O}$-group schemes defined by $\iota$: for any $\mathcal{O}$-algebra $R$, the induced morphism on $R$-points is the composition $A(R) = A \hookrightarrow G(\mathcal{O}) \to G(R)$.

**Lemma 4.3.** The morphism $A \times G^0 \to G$

defined by $(a, g) \mapsto \iota(a) \cdot g$ is an isomorphism of $\mathcal{O}$-schemes.

**Proof.** Consider the algebra morphism $\varphi : \mathcal{O}(G) \to \prod_{a \in A} \mathcal{O}(G^0)$ induced by our morphism. From the remarks above, we know that the algebra morphism $\mathbb{F} \otimes_{\mathcal{O}} \varphi$ is an isomorphism. Here $\prod_{a \in A} \mathcal{O}(G^0)$ is finitely generated as an $\mathcal{O}(G)$-module, since $\mathcal{O}(G^0)$ is. Hence, by (a variant for discrete valuation rings of) [BR, Lemma 1.4.1], we deduce that $\varphi$ is an isomorphism. □

4.2. **Statement.** Let us consider the Grothendieck groups

$K(G), \quad K(G_K), \quad K(G_F)$

of the categories of (algebraic) $G$-modules of finite type over $\mathcal{O}$, of finite-dimensional (algebraic) $G_K$-modules, and of finite-dimensional (algebraic) $G_F$-modules, respectively. We will also denote by $K_{pr}(G)$ the Grothendieck group of the exact category of $G$-modules which are free of finite rank over $\mathcal{O}$. Following [Se] we consider the natural morphisms of abelian groups

$$
\begin{array}{ccc}
K_{pr}(G) & \sim \to & K(G) \\
\downarrow & & \downarrow d_G \\
K(G_K) & & K(G_F)
\end{array}
$$

Here, on the upper line, the left horizontal map (which is induced by the natural inclusion of categories) is an isomorphism by [Se, Proposition 4]. The right horizontal map (induced by the exact functor $\mathbb{K} \otimes_\mathcal{O} (-)$) is surjective by [Se, Théorème 1]. The map from the top left-hand corner to the group on the bottom line is induced by the (exact) functor $\mathbb{F} \otimes_\mathcal{O} (-)$. Finally, the map $d_G$ is the “decomposition” morphism from [Se, Théorème 2].

The main result of this section is the following.

**Theorem 4.4.** All the maps in (4.2) are isomorphisms.

According to [Se, Théorème 3], if $d_G$ is surjective, then the right-hand morphism on the upper line is automatically an isomorphism. Thus, to prove Theorem 4.4, it is enough to prove that $d_G$ is an isomorphism. This will be accomplished in §4.5 below.
4.3. Lattices. Our starting point will be the main result of [Se], which is applicable here thanks to Lemma 4.1. This result asserts that if we consider the diagram

\[
\begin{array}{ccc}
K_{pr}(G^o) & \sim & K(G^o) \\
\downarrow d_{G^o} & & \downarrow d_{G^o} \\
K(G^o_K) & \sim & K(G^o_K)
\end{array}
\]

(similar to (4.2) but for the group \(G^o\), then the decomposition morphism \(d_{G^o}\) is an isomorphism, so that all the maps in (4.3) are isomorphisms.

More precisely, let us a fix a split torus \(T \subset G^o\) and set \(X := X^*(T)\). Choosing a system of positive roots in the root system of \((G^o, T)\), we obtain a Borel subgroup \(B \subset G^o\) containing \(T\) (chosen such that \(B\) is the negative Borel subgroup), and a subset \(X^+ \subset X\) of dominant weights.

By the well known representation theory of connected reductive groups over algebraically closed fields, both the set of isomorphism classes of simple \(G^o_F\)-modules and the set of isomorphism classes of simple \(G^o_K\)-modules are in bijection with \(X^+\). More concretely, if \(\lambda \in X^+\) and if \(L^\lambda_F(\lambda)\) is a simple \(G^o_F\)-module of highest weight \(\lambda\), then there exists a simple \(G^o_K\)-module \(L^\lambda_K(\lambda)\) and an isomorphism \(K \otimes_K V^\lambda_K \cong V^\lambda_F\) (see e.g. [Se, §4.6] or [Ja, Corollary II.2.9] for details). If \(V^\lambda_F \subset V^\lambda_K\) is a \(G^o\)-stabilized \(\mathcal{O}\)-lattice, then the class of \(F \otimes \mathcal{O} V^\lambda\) in \(K(G^o_K)\) coincides with the class of the Weyl module \(\Delta^\lambda_F(\lambda)\) of highest weight \(\lambda\) (because \(L^\lambda_F(\lambda)\) and \(\Delta^\lambda_F(\lambda)\) have the same characters). In fact, it is well known that the lattice \(V^\lambda_F\) can be chosen in such a way that \(F \otimes \mathcal{O} V^\lambda_F \cong \Delta^\lambda_F(\lambda)\) as \(G^o_F\)-modules. For each \(\lambda\) we will fix such a lattice, and denote it by \(L^\lambda(\lambda)\).

In the present setting, \(A\) is the group of components both of \(G^o_F\) and of \(G^o_K\). Identifying \(T^o_F\) and \(T^o_K\) with the universal maximal tori of \(G^o_F\) and \(G^o_K\) respectively (via the choice of Borel subgroups obtained from \(B\) by base change), we obtain two actions of \(A\) on \(X = X^*(T^o_F) = X^*(T^o_K)\), see §2.2. The description of this action involves the property that Borel subgroups are conjugate, which is not true over \(\mathcal{O}\); so it is not clear from the definition that they must coincide. In the next lemma we will show that they do at least coincide on \(X^+\).

**Lemma 4.5.** The two actions of \(A\) on \(X\) agree on \(X^+\).

*Proof.* Let us provisionally denote the two actions of \(A\) on \(X\) by \(\cdot_F\) and \(\cdot_K\). Since \(A\) acts by algebraic group automorphisms on \(G^o\), this group acts on all the Grothendieck groups in (4.3), and all the maps in this diagram are obviously \(A\)-equivariant. Now for \(\lambda \in X^+\) we have \(a \cdot [L^\lambda_F(\lambda)] = [L^\lambda_K(a \cdot_K \lambda)]\). Hence

\[
d_{G^o}(a \cdot [L^\lambda_F(\lambda)]) = [\Delta^\lambda_F(a \cdot_F \lambda)].
\]

On the other hand, since \(d_{G^o}\) is \(A\)-equivariant we have

\[
d_{G^o}(a \cdot [L^\lambda_F(\lambda)]) = a \cdot [\Delta^\lambda_F(\lambda)] = [\Delta^\lambda_F(a \cdot_F \lambda)]
\]

(see (2.3)). We deduce that \([\Delta^\lambda_F(a \cdot_K \lambda)] = [\Delta^\lambda_F(a \cdot_F \lambda)]\), hence that \(a \cdot_K \lambda = a \cdot_F \lambda\). \(\square\)

From now on we fix \(\lambda \in X^+\). It follows in particular from Lemma 4.5 that the two possible definitions of the subgroup \(A^\lambda \subset A\) (see §2.4) coincide.

**Lemma 4.6.**

1. We have \(\text{End}_{G^o}(L^\lambda(\lambda)) = \mathcal{O}\).
(2) For any \( a \in A^\lambda \), there exists an isomorphism of \( G^\circ \)-modules 
\[ \iota(a)L_\varpi(\lambda) \cong L_\varpi(\lambda). \]

**Proof.** We only explain the proof of (2); the proof of (1) is similar. Consider the object 
\[ R\text{Hom}_{G^\circ}(L_\varpi(\lambda), \iota(a)L_\varpi(\lambda)) \]
of the derived category of \( O \)-modules. By [Ja, Lemma II.B.5 and its proof], this complex has bounded cohomology, and each of its cohomology objects is finitely generated. This implies that it is isomorphic (in the derived category) to a finite direct sum of shifts of finitely generated \( O \)-modules.

It follows from [MR, Proposition A.6 and Proposition A.8] that we have
\[ \mathbb{F} \otimes \bigotimes_a \text{Hom}_{G^\circ}(L_\varpi(\lambda), \iota(a)L_\varpi(\lambda)) \cong R\text{Hom}_{G^\circ}(L_\varpi(\lambda), \Delta_F(\lambda), \Delta_F(\lambda)), \]
\[ \mathbb{K} \otimes \bigotimes_a \text{Hom}_{G^\circ}(L_\varpi(\lambda), \iota(a)L_\varpi(\lambda)) \cong R\text{Hom}_{G^\circ}(L_\varpi(\lambda), \Delta_F(\lambda), L_\varpi(\lambda)). \]

Now we have \( R\text{Hom}_{G^\circ}(L_\varpi(\lambda), \Delta_F(\lambda), L_\varpi(\lambda)) \cong \mathbb{K} \), so that \( \text{Hom}_{G^\circ}(L_\varpi(\lambda), \iota(a)L_\varpi(\lambda)) \) is a sum of \( O \) and a torsion module. But since \( \text{Hom}_{G^\circ}(\Delta_F(\lambda), \Delta_F(\lambda)) = \mathbb{F} \), this torsion module is zero; in other words we have \( \text{Hom}_{G^\circ}(L_\varpi(\lambda), \iota(a)L_\varpi(\lambda)) \cong O \). If \( f : L_\varpi(\lambda) \rightarrow \iota(a)L_\varpi(\lambda) \) is a generator of this rank-1 \( O \)-module, the \( G_F \)-module morphism \( F \otimes O f \) is an isomorphism, so that \( f \) is also an isomorphism. \( \square \)

### 4.4. Comparison of twisted group algebras.
We continue with the setting of §4.3 (and in particular with our fixed \( \lambda \in X^+ \)).

By Lemma 4.6 we can choose, for any \( a \in A^\lambda \), an isomorphism \( \theta_a : L_\varpi(\lambda) \cong \iota(a)L_\varpi(\lambda) \). Then \( \mathbb{K} \otimes \bigotimes_a \theta_a \) is an isomorphism from \( L_\varpi(\lambda) \) to \( \iota(a)L_\varpi(\lambda) \), and for \( a, b \in A^\lambda \) the scalar \( \alpha(a, b) \in \mathbb{K} \) defined in §2.4 using these isomorphisms in fact belongs to \( O^\times \). In particular, if \( \mathcal{A}_F^\lambda \) is the associated twisted group algebra (over \( \mathbb{K} \)), then the \( O \)-lattice \( \mathcal{A}_O^\lambda := \bigoplus_{a \in A^\lambda} O \cdot \rho_a \) is an \( O \)-subalgebra in \( \mathcal{A}_F^\lambda \). On the other hand, \( \mathbb{F} \otimes \bigotimes_a \theta_a \) is an isomorphism from \( \Delta_F(\lambda) \) to \( \iota(a)\Delta_F(\lambda) \), and by Remark 3.2 the algebra \( \mathcal{A}_F^\lambda \) from §2.4 (now for the group \( G_F \) and its simple module \( L_\varpi(\lambda) \)) can be described as the twisted group algebra of \( A^\lambda \) defined by the cocycle sending \( (a, b) \) to the image of \( \alpha(a, b) \) in \( \mathbb{F} \).

Summarizing, we have obtained an \( O \)-algebra \( \mathcal{A}_O^\lambda \) which is free over \( O \) and such that
\[ \mathbb{K} \otimes \bigotimes_a \mathcal{A}_O^\lambda \cong \mathcal{A}_F^\lambda, \quad \mathbb{F} \otimes \bigotimes_a \mathcal{A}_O^\lambda \cong \mathcal{A}_F^\lambda. \]

From Lemma 2.19 we know that \( \mathcal{A}_F^\lambda \) and \( \mathcal{A}_F^\lambda \) are products of matrix algebras (over \( \mathbb{F} \) and \( \mathbb{K} \) respectively). In fact, the same arguments show that \( \mathcal{A}_F^\lambda := \mathbb{K} \otimes \bigotimes_a \mathcal{A}_F^\lambda \) is also a product of matrix algebras (over \( \mathbb{K} \)). Hence we are in the setting of Tits’ deformation theorem (see e.g. [GP, Theorem 7.4.6]), and we deduce that we have a canonical bijection between the sets of isomorphism classes of simple \( \mathcal{A}_F^\lambda \)-modules and isomorphism classes of simple \( \mathcal{A}_K^\lambda \)-modules, which sends a simple module \( M \) to \( \mathbb{F} \otimes M_{\varpi} \), where \( M_{\varpi} \) is any \( \varpi \)-stable \( O \)-lattice in \( M \).

Let now \( E \) be a simple \( \mathcal{A}_K^\lambda \)-module. The same procedure as in §2.5 allows us to define a \( G_K^\lambda \)-module structure on \( E \otimes_K L_\varpi(\lambda) \), where \( G_K^\lambda \) is the inverse image of \( A^\lambda \) under the map \( G_K \rightarrow A \) induced by \( \varpi \).
Lemma 4.7. Let \( \tilde{E} \) be the simple \( \mathcal{A}_E^\lambda \)-module corresponding to \( E \) under the bijection above. Then we have

\[
d_G([\text{Ind}_{G_\mathbb{F}}^G(E \otimes L_\mathbb{F}(\lambda))]) = [\Delta_{\mathbb{F}}(\lambda, \tilde{E})],
\]

where \( G_\mathbb{F} \) is the inverse image of \( \mathbb{A}^\lambda \) under the map \( G_\mathbb{F} \to A \) induced by \( \varpi \).

Proof. If \( E_0 \subset E \) is an \( \mathcal{A}_E^\lambda \)-stable lattice in \( E \), then \( E_0 \otimes_{\mathcal{O}} L_\mathbb{F}(\lambda) \) has a natural structure of \( G^\lambda \)-module (where \( G^\lambda = \varpi^{-1}(\mathbb{A}^\lambda) \)), and is a \( G^\lambda \)-stable lattice in \( E \otimes L_\mathbb{F}(\lambda) \). Inducing to \( G \), we deduce that \( \text{Ind}_{G_\mathbb{F}}^G(E_0 \otimes_{\mathcal{O}} L_\mathbb{F}(\lambda)) \) is a \( G \)-stable lattice in \( \text{Ind}_{G_\mathbb{F}}^G(E \otimes L_\mathbb{F}(\lambda)) \), whose modular reduction is \( \Delta_{\mathbb{F}}(\lambda, \tilde{E}) \).

\( \square \)

4.5. Invertibility of \( d_G \). We can now prove that \( d_G \) is an isomorphism, which will finish the proof of Theorem 4.4.

In fact, for any \( \lambda \in X^+ \), since \( \mathcal{A}_E^\lambda \) is a product of matrix algebras the assignment

\[
E \mapsto \mathbb{K} \otimes_{\mathcal{O}} E
\]

induces a bijection between the sets of isomorphism classes of simple modules for the algebras \( \mathcal{A}_E^\lambda \) and \( \mathcal{A}_F^\lambda \) from §4.4. Then, using Theorem 2.16 and arguing as in [Sc, §3.6], we see that the similar operation induces a bijection between the sets of isomorphism classes of simple \( G_\mathbb{F} \)-modules and of simple \( G_\mathbb{F} \)-modules.

Let us now fix a subset \( \Lambda \subset X^+ \) of representatives for the \( A \)-orbits on \( X^+ \). By the remarks above, the classes of the modules \( \text{Ind}_{G_\mathbb{F}}^G(E \otimes L_\mathbb{F}(\lambda)) \), where \( (\lambda, E) \) runs over the pairs consisting of an element \( \lambda \in \Lambda \) and a simple \( \mathcal{A}_F^\lambda \)-module, form a basis of \( K(G_\mathbb{F}) \) (see in particular Remark 2.17(1)). In view of Lemma 4.7 and Theorem 3.7, the image of this basis under \( d_G \) is a basis of \( K(G_\mathbb{F}) \). Hence, \( d_G \) is indeed an isomorphism.
