The super-inflationary phase is predicted by the Loop Quantum Cosmology. In this paper we
study the creation of gravitational waves during this phase. We consider the inverse volume correc-
tions to the equation for the tensor modes and calculate the spectrum of the produced gravitons.
The amplitude of the obtained spectrum as well as maximal energy of gravitons strongly depend on
the evolution of the Universe after the super-inflation. We show that a further standard inflationary
phase is necessary to lower the amount of gravitons below the present bound. In case of the lack of
the standard inflationary phase, the present intensity of gravitons would be extremely large. These
considerations give us another motivation to introduce the standard phase of inflation.

I. INTRODUCTION

The cosmological creation of the gravitational waves was proposed by Grishchuk [1] in the mid-seventies. Since
that time this phenomenon has been studied extensively, especially in the context of the inflation. The accelerating
expansion phase gives the conditions for the abundant creation of the gravitational waves. Gravitons produced during
the inflation fill the entire space in the form of a stochastic background. Together with the scalar modes, produced
during the inflation, they form primordial perturbations leading to the structure formation. The analysis of the cosmic
microwave background (CMB) and large scale structures gives therefore the possibility of testing inflationary models.
In the case of the CMB the impact of the gravitational waves comes from the primordial spectrum and from tensor
Sachs-Wolfe effects. The Sachs-Wolfe effect is somehow secondary and leads to the CMB anisotropies as the result of
the scattering of CMB photons on the relic gravitons. The form of this anisotropies is given by

\[
\left( \frac{\Delta T}{T} \right)_t = -\frac{1}{2} \int_{\tau_1}^{\tau_2} d\tau \, h_{ij} \n^i \n^j
\]

where \( h_{ij} \) describes tensor modes and \( n^i \) is the vector parallel to the unperturbed geodesics. The influence of the
gravitational waves for the CMB is however to weak to be observed directly with the present observational abilities.
Another possible method to detect gravitational waves is to use of the antennas like LIGO, VIRGO, TAMA or GEO600
[2, 3]. Although these detectors are now very sensitive this is still not enough to detect directly the gravitational
waves background [4]. It may look pessimistic, we hope however that some further improvement of the observational
skills bring us the observational evidence, so needful for the further theoretical improvements.

In this paper we consider a new type of the inflation which naturally occurs in the Loop Quantum Cosmology
[5]. This is so called the super-inflationary scenario [6, 7] and is a result of the quantum nature of spacetime in the
Planck scales. The spacetime is namely discrete in the quantum regime and its evolution is governed by discrete
equations. However for the scales greater than \( a_\ell = \sqrt{\gamma} \l_P \) (\( \gamma \) is so called Barbero-Immirzi parameter) the evolution
of the spacetime can be described by the Einstein equations with quantum corrections. For typical values of the
quantum numbers, super-inflationary phase takes place in this semi-classical region.

Our goal is to describe the production of the gravitational waves during the super-inflation. This problem was
preliminary analysed in Ref. [8], but quantum corrections to the equation for tensor modes was not included to
calculate the spectrum of the gravitons. In this paper we include so called inverse volume corrections to the equation
for evolution of the tensor modes and then calculate the spectrum of produced gravitational waves. The equations
for the tensor modes was recently derived by Bojowald and Hossain [9]. They had analysed the inverse volume

∗Electronic address: jakubm@poczta.onet.pl
†Electronic address: uoszydlo@cyf-kr.edu.pl
corrections and corrections from holonomies. In this paper we concentrate on these first ones. The quantum corrections are generally complicated functions but they have simple asymptotic behaviours. To calculate the productions of gravitons during some process we need somehow to know only initial and final states, where asymptotic solutions are good approximation. In these regimes calculations can be done analytically. We use numerical solutions to match them.

The organisation of the text is the following. In section II we fix the semi-classical dynamics. Then in section III we consider creation of the gravitons on the defined background. In section IV we summarise the results.

II. BACKGROUND DYNAMICS

The formulation of Loop Quantum Gravity bases on the Ashtekar variables [10] and holonomies. The Ashtekar variables replace the spatial metric field $q_{ab}$ in the canonical formulation as follow

$$A^i_a = \Gamma^i_a + \gamma K^i_a, \quad E^a_i = \sqrt{\det q} e^a_i \quad (2)$$

where $\Gamma^i_a$ is the spin connection defined as

$$\Gamma^i_a = -\epsilon^{ijk} e^b_j \partial_j e^a_k + \frac{1}{2} \epsilon^{ijk} e^a_j e^b_k$$

(4)

and the $K^i_a$ is the intrinsic curvature. The $e^a_i$ is the inverse of the co-triad $e^a_i$ defined as $q_{ab} = e^a_i e^b_i$. In terms of the Ashtekar variables the full Hamiltonian for general relativity is a sum of constraints

$$H_G^{\text{tot}} = \int d^3 x \left( N^i G_i + N^a C_a + N h_{ac} \right), \quad (5)$$

where

$$C_a = E^b_i F^i_{ab} - (1 - \gamma^2) K^i_a G_i, \quad G_i = D_a E^a_i \quad (6)$$

and the scalar constraint has a form

$$H_G := \int d^3 x N(x) h_{ac} = \frac{1}{16\pi G} \int d^3 x N(x) \left( \frac{E^a_i E^b_j}{\sqrt{|\det E|}} e^{ij} F_{ab} - 2(1 + \gamma^2) \frac{E^a_i E^b_j}{\sqrt{|\det E|}} K^i_a K^j_b \right) \quad (7)$$

with $F = dA + \frac{1}{2}[A, A]$. The full Hamiltonian of theory is a sum of the gravitational and matter part. With convenience as a matter part we choose the scalar field with the Hamiltonian

$$H_\phi = \int d^3 x N(x) \left( \frac{\pi^2_\phi}{2 \sqrt{|\det E|}} + \frac{E^a_i E^b_j \partial_a \phi \partial_b \phi}{\sqrt{|\det E|}} + \frac{1}{\sqrt{\det E}} V(\phi) \right), \quad (8)$$

We assume here that field $\phi$ is homogeneous and start his evolution from the minimum of potential $V(\phi)$. The second assumption states that contribution from potential term is initially negligible. So the density of Hamiltonian $H_\phi$ is simplified to the form $H_\phi = (1/2) \pi^2_\phi / \sqrt{|\det E|}$. The term $1/\sqrt{|\det E|}$ for the classical FRW universe corresponds to $1/a^3$ where $a$ is the scale factor. On the quantum level term $1/\sqrt{|\det E|}$ is quantised and have discrete spectrum. In the regime $a \gg a_i$ we can however use the approximation $1/\sqrt{|\det E|} = D/a^3$ where

$$D(q) = q^{3/2} \left\{ \frac{3}{2l} \left( 1 + \frac{q}{1 + q - \text{sgn}(q - 1)|q - 1|^{l+1}} \right) \right\}^{3/(2 - 2l)} \quad (9)$$

and $q = (a/a_*)^2$ with $a_* = \gamma_j/3l_1$. Function (9) depends on the ambiguity parameter $l$. As it was shown by Bojowald [11] the value of this parameter is quantised according to $l_k = 1 - (2k)^{-1} \geq 1/2, k \in \mathbb{N}$. For the further
The equation of motion for the scalar field with quantum corrections has the form

\[ \tau = \frac{3}{1 + l} \left( \frac{2}{2 - l} \right)^{3/(2 - l)} a_*^{-3(2 - l)/(1 - l)} \quad \text{and} \quad n = 3(2 - l)/(1 - l). \]  

Now, due to the Hamilton equations we can derive the Friedmann and Raychaudhuri equations for the flat FRW universe filled with a homogeneous scalar field

\[ H^2 = \frac{8\pi G}{3} \left[ \frac{\dot{\phi}^2}{2D} + V(\phi) \right], \]  
\[ \frac{\ddot{a}}{a} = -\frac{8\pi G}{3} \left[ \frac{\dot{\phi}^2}{D} \left( 1 - \frac{\dot{D}}{4HD} \right) - V(\phi) \right]. \]

The equation of motion for the scalar field with quantum corrections has the form

\[ \ddot{\phi} + \left( 3H - \frac{\dot{D}}{D} \right) \dot{\phi} + D \frac{dV}{d\phi} = 0. \]

As we mentioned before, for the further investigations we simplify equations (12), (13) and (14) assuming \( V(\phi) = 0 \). The expression for the quantum correction \( D \) is complicated and it is impossible to find an analytical solution for the equations of motion. In fact we even do not need it for the future investigations. To calculate the spectrum of gravitons we need to know analytical solutions only for the inner and outer states. We choose the representative value \( l = 3/4 \). In the semi-classical region \( a_* \gg a \gg a_i \) expression (9) simplifies to the form

\[ D = D_* a^n \]  

where

\[ D_* = \left( \frac{3}{1 + l} \right)^{3/(2 - 2l)} a_*^{-3(2 - l)/(1 - l)} \]

and \( n = 3(2 - l)/(1 - l) \).

The chosen value of \( a \) must be chosen in a proper way for the given regions. We will discuss this question in more details later.

Our point of reference is the numerical solution. To make this description complete we must choose the proper boundary conditions for the numerical solution. We use here the condition for the Hubble radius which must be larger than the limiting value \( a_i \) [12], what gives us

\[ k \simeq |H|a < \frac{a}{a_i} \Rightarrow |H|a_i < 1. \]  

The next condition requires that the scale factor should be greater than \( a_i \) at the maximum of (9) to obtain super-inflationary phase. It is fulfilled taking \( a|_{\tau_0} = a_* \) for some value of the conformal time \( \tau_0 \) and \( j = 100x \). In fact the conformal time is unphysical variable and their value can be chosen arbitrary. The physical outcomes do not depend on coordinates because the theory is invariant under local diffeomorphisms. So as an example we can choose

\[ a|_{\tau_0 = -4} = a_* \]
\[ a'|_{\tau_0 = -4} = l_{Pl} \]

The chosen value of \( a'|_{\tau_0 = -4} \) holds the condition (17). Namely for \( j = 100 \) we have \( |H_*|a_i = 0.084 < 1 \). The numerical solution is shown in Fig. 1 as a black line. We fix the boundary approximations in \( \tau_1 = -20 \) and \( \tau_2 = -1 \). The the
FIG. 1: Numerically calculated evolution of the scale factor (top black line) and the Hubble parameter (bottom black line) for the model with $j = 100$, $l = 3/4$ and with initial conditions (18) and (19). The approximated solutions described by (15) and (22).

The numerical solution gives us for these points

$$a|_{\tau_1 = -20} = \frac{0.536}{l_{Pl}}, \quad a'|_{\tau_1 = -20} = 0.007l_{Pl} \quad \text{(20)}$$

$$a|_{\tau_2 = -1} = \frac{3.912}{l_{Pl}}, \quad a'|_{\tau_2 = -1} = 0.461l_{Pl} \quad \text{(21)}$$

Now with the use of expressions (16) we can fix the approximated solutions. However when we use formula (16) directly to calculate parameters in solution (15) for the outer state we obtain complex $\xi$. It is due to the expression under square ($p = 1/2$) is negative. So to put away complex numbers we redefine the exit solution to the form

$$a = \kappa \sqrt{\tau + \zeta} \quad \text{(22)}$$

where

$$\kappa = -i\xi \quad \text{(23)}$$

$$\zeta = -\beta \quad \text{(24)}$$

We show in Fig. 1 how these approximated solutions match with solutions obtained numerically. As we can see these approximated solutions well describe the evolution in the neighbourhood of $a_*$.  

### III. GRAVITATIONAL WAVES

We have already mentioned in section I that gravitational waves can be abundantly produced during the accelerating phase. In this section we want to show in details how it works and calculate properties of produced gravitons. To describe the spectrum of gravitons it is common to use the parameter

$$\Omega_{gw}(\nu) = \frac{\nu}{\rho_c} \frac{d\rho_{gw}}{d\nu} \quad \text{(25)}$$

where $\rho_{gw}$ is the energy density of gravitational waves and $\rho_c$ is present critical energy density. Our goal in this section is to calculate the function $\Omega_{gw}(\nu)$ for the gravitons produced during the super-inflationary phase.

The gravitational waves $h_{ij}$ are the perturbations of the background spacetime in the form

$$ds^2 = a^2(\tau) \left[-d\tau^2 + (\delta_{ij} + h_{ij})dx^idx^j\right] \quad \text{(26)}$$

where $|h_{ij}| \ll 1$. Using constraints $h_i^i = \nabla_i h_j^j = 0$ we can see that tensor $h_{ij}$ have only two independent components $h_1^1 = -h_2^2 = h_+$ and $h_1^2 = h_2^1 = h_\times$. These components correspond to two different polarisations of gravitational
waves. Inserting the perturbed metric (26) to the Hilbert-Einstein action $S_{\text{H-E}} = \frac{1}{16\pi G} \int d^4x \sqrt{-g} R$ gives the series $S_{\text{H-E}} = S^{(0)} + S^{(1)} + S^{(2)} + \ldots$, where the second order term have a form

$$S^{(2)}_t = \frac{1}{64\pi G} \int d^4x a^3 \left[ \partial_i h^j_i \partial_j h^i_j - \frac{1}{a^2} \nabla_k h^j_i \nabla_k h^i_j \right] = \frac{1}{32\pi G} \int d^4x a^3 \left[ h_x^2 + h_+^2 - \frac{1}{a^2} \left( \nabla h_x \right)^2 - \frac{1}{a^2} \left( \nabla h_+ \right)^2 \right]$$

(27)

and give us the action for the gravitational waves. The two kinds of polarisations are not coupled and can be treated separately. To normalise the action and simplify the notation it us useful to introduce the variable

$$h = \frac{h_+}{\sqrt{16\pi G}} = \frac{h_x}{\sqrt{16\pi G}},$$

(28)

what leads to the expression for the action in the form

$$S_t = \frac{1}{2} \int d^4x a^3 \left[ h_x^2 - \frac{1}{a^2} \left( \nabla h \right)^2 \right].$$

(29)

This action is the same like the action for an inhomogeneous scalar field without the potential. Inverse volume corrections can be therefore introduced in the same way like in the case of the scalar field. As we mentioned in Introduction there are also holonomy corrections to this action. Here we consider however the influence from the better examined inverse volume corrections. Introducing inverse volume corrections in the action (29) we obtain equation

$$h'' + 2 \frac{a'}{a} \left( 1 - \frac{1}{2} \frac{a D}{D a} \right) h' - D \nabla^2 h = 0.$$  

(30)

This equation was derived in our previous work [8]. As we mentioned earlier the equation for tensor modes has been also derived by Bojowald and Hossain [9]. They had considered perturbations of Ashtekar variables in the form $A = \bar{A} + \delta A$ and $E = \bar{E} + \delta E$ and in the fully canonical approach they have obtained equation

$$h'' + 2 \frac{a'}{a} \left( \alpha - \frac{1}{2} \frac{a}{D a} \frac{d\alpha}{da} \right) h' - \alpha^2 \nabla^2 h = 0.$$  

(31)

The function $\alpha$, which introduce inverse volume correction, have the same generic behaviour like the function $D$. Assuming $\alpha = D$, equations (30) and (31) differ in the second and last terms. The difference in the last term is weak and comes only from square of the function $D$. The more important is to investigate the second term. In the Fig. 2 we show expressions from the brackets in the equations (30) and (31). We see, that difference start to be important

![FIG. 2: Comparison of the expressions from the brackets in the equations (30) and (31), assuming $\alpha = D$. The top line for small $a$ (red line) correspond to the equation (31). The bottom line for small $a$ (blue line) correspond to the equation (30). Plots for the model with $j = 100$ and $l = 3/4$.](image-url)
for small values of the scale factor. However, as we will see later, the production of gravitons is most effective for $a > 1$ (in the Planck units). In this region both approaches are qualitatively the same. As a second example, we assume $\alpha = \sqrt{D}$, then only expression in the bracket differ equations (30) and (31). We show these difference in the Fig. 3. The main conclusions from these observations is that for $a \gtrsim 1.5l_{Pl}$ both considered approaches are the same.

![Fig. 3: Comparison of the expressions from the brackets in the equations (30) and (31), assuming $\alpha = \sqrt{D}$. The top line for small $a$ (red line) correspond to the equation (31). The bottom line for small $a$ (blue line) correspond to the equation (30). Plots for the model with $j = 100$ and $l = 3/4$.](image_url)

However, for small values of the scale factor, the friction terms becomes more negative for the equation (30). In the equation (31) friction term comes to zero for small values $a$. This behaviour is directly connected to creation of the gravitons. Generally, more negative friction term more gravitons produced. The effects of corrections in the equation (31) lower the negative friction, but only in the region where the production of the gravitons is not effective. In the rest of this work we concentrate on the equation (30).

As it was shown by Mulryne and Nunes [13], in the context of scalar field perturbations, it is useful to introduce the variable $u = aD^{-1/2}h$ and rewrite the action (29) with quantum corrections to the form

$$S_t = \frac{1}{2} \int d\tau d^3x [u'^2 - D\delta^{ij}\partial_i u \partial_j u - m_{\text{eff}}^2 u^2]$$

where

$$m_{\text{eff}}^2 = -\frac{\sqrt{D}}{a} \left( \frac{a}{\sqrt{D}} \right)^\alpha.$$ (33)

Till now the considerations of the gravitational waves has been purely classical. The next step is the quantisation of the classical gravitational waves what brings us the concept of gravitons. To quantise the field $u$ we need to firstly calculate conjugated momenta

$$\pi(\tau, x) = \frac{\delta S_t}{\delta u'} = u'.$$ (34)

The procedure of quantisation is the simple change of fields $u$ and $\pi$ for the operators just adding hats and to introduce the relations of commutation. We decompose operators considered for the Fourier modes

$$\hat{u}(\tau, x) = \frac{1}{2(2\pi)^{3/2}} \int d^3k \left[ \hat{u}_k(\tau) e^{ik\cdot x} + \hat{u}_k^\dagger(\tau) e^{-ik\cdot x} \right],$$ (35)

$$\hat{\pi}(\tau, x) = \frac{1}{2(2\pi)^{3/2}} \int d^3k \left[ \hat{\pi}_k(\tau) e^{ik\cdot x} + \hat{\pi}_k^\dagger(\tau) e^{-ik\cdot x} \right].$$ (36)
where the Fourier components fulfil the relations of commutation

\[ [\hat{u}_k(\tau), \hat{p}^\dagger_p(\tau)] = i \delta^{(3)}(k - p), \]  
\[ [\hat{u}_k(\tau), \hat{p}_p(\tau)] = i \delta^{(3)}(k - p), \]  
\[ [\hat{u}_k(\tau), \hat{p}^\dagger_p(\tau)] = i \delta^{(3)}(k + p), \]  
\[ [\hat{u}_k(\tau), \hat{p}_p(\tau)] = i \delta^{(3)}(k + p). \]  

To express the Fourier modes in terms of the annihilation and creation operators we need to solve the quantum Hamilton equations

\[ \dot{u}' = i[\hat{H}_t, \hat{u}], \]  
\[ \dot{\pi}' = i[\hat{H}_t, \hat{\pi}]. \]  

The Hamilton operator have the form

\[ \hat{H}_t = \frac{1}{2} \int d^3x [\hat{\pi}^2 + D\delta^{ij} \partial_i \hat{u}_j \hat{u}_i + m^2_{\text{eff}} \hat{\pi}^2] \]
\[ = \frac{1}{2} \frac{1}{4(2\pi)^3} \int d^3x \frac{1}{4} \int d^3kd^3q [\hat{\pi}_k e^{ik \cdot x} + \hat{p}_k e^{-ik \cdot x}] [\hat{\pi}_q e^{iq \cdot x} + \hat{p}_q e^{-iq \cdot x}]
\]
\[ + D\delta^{ij} \left[ k_i \hat{u}_k e^{ik \cdot x} - k_i \hat{u}^\dagger_k e^{-ik \cdot x} \right] i \left[ q_j \hat{u}_q e^{iq \cdot x} - q_j \hat{u}^\dagger_q e^{-iq \cdot x} \right]
\]
\[ + m^2_{\text{eff}} \left[ \hat{u}_k e^{ik \cdot x} + \hat{u}^\dagger_k e^{-ik \cdot x} \right] \left[ \hat{u}_q e^{iq \cdot x} + \hat{u}^\dagger_q e^{-iq \cdot x} \right]
\]
\[ = \frac{1}{4} \int d^3k \left[ \hat{u}_k \hat{\pi}_k \hat{p}_k + \hat{u}^\dagger_k \hat{\pi}_k \hat{p}_k + (Dk^2 + m^2_{\text{eff}}) \left( \hat{u}_k \hat{p}^\dagger_k + \hat{u}^\dagger_k \hat{p}_k \right) \right] \]  

where we inserted decompositions (35) and (36). When we apply the Hamiltonian (43) and the decompositions (35) and (36), the Hamilton equations (41) and (42) take the forms

\[ \dot{u}_k = \hat{p}_k, \]  
\[ \dot{\pi}_k = - (Dk^2 + m^2_{\text{eff}}) \hat{u}_k. \]  

The general solution of these equations has the form

\[ \hat{u}_k(\tau) = \hat{a}_k f(k, \tau) + \hat{a}^\dagger_{-k} f^*(k, \tau), \]  
\[ \hat{\pi}_k(\tau) = \hat{a}_k g(k, \tau) + \hat{a}^\dagger_{-k} g^*(k, \tau). \]  

where \( f(k, \tau)' = g(k, \tau) \). When we insert these solutions to the Fourier decompositions (35) and (36) we simply obtain

\[ \hat{u}(\tau, x) = \frac{1}{(2\pi)^{3/2}} \int d^3k \left[ f(k, \tau) \hat{a}_k e^{ik \cdot x} + f^*(k, \tau) \hat{a}^\dagger_{-k} e^{-ik \cdot x} \right], \]
\[ \hat{\pi}(\tau, x) = \frac{1}{(2\pi)^{3/2}} \int d^3k \left[ g(k, \tau) \hat{a}_k e^{ik \cdot x} + g^*(k, \tau) \hat{a}^\dagger_{-k} e^{-ik \cdot x} \right]. \]

The mode functions fulfils the so called Wronskian condition

\[ f^*(k, \tau) g(k, \tau) - f(k, \tau) g^*(k, \tau) = -i \]  

as a result of relations of commutation (37-40). These relations is important to normalise properly the mode functions.

The Hamilton equations (44) and (45) together with (46) give us the equation for the mode function

\[ \frac{d^2}{d\tau^2} f(k, \tau) + [Dk^2 + m^2_{\text{eff}}] f(k, \tau) = 0. \]  

This equations has two regimes. The first one called adiabatic corresponds to the situation when \( Dk^2 + m^2_{\text{eff}} \equiv \Gamma \ll 0 \). The second one leads to the super-adiabatic amplification and corresponds to the situation when \( \Gamma \gg 0 \). The creation of the gravitational waves corresponds to the case of the super-adiabatic amplification.
We can now investigate which modes are amplified. The condition $\Gamma \ll 0$ corresponds to $Dk^2 \ll -m_{\text{eff}}^2$. In Fig. 4 we see the evolution of $-m_{\text{eff}}^2$. As we see the condition for the creation of gravitational waves is fulfilled in the region of the super-inflation ($\tau \in [\sim -6, \sim -4]$). In the right panel we can see the evolution of $\Gamma$ for three different values of $k$.

The value of $k$ is dimensionless in the undertaken scheme. To obtain a dimensional value we must multiply it simply by the corresponding scale factor which has a dimension of length. The wave number $k$, for example for the final state $a_f$, corresponds to the frequency

$$
\nu = \frac{k}{2\pi a_f} \left( \frac{a_t}{a_{\text{today}}} \right)
$$

measured today. The important task is to calculate the factor $a_{\text{today}}/a_t$. We can make the decomposition

$$
\frac{a_{\text{today}}}{a_t} = \frac{a_{\text{today}}}{a_{\text{dec}}} \frac{a_{\text{dec}}}{a_{\text{rh}}} \frac{a_{\text{rh}}}{a_{i\text{-end}}} \frac{a_{i\text{-end}}}{a_{i\text{-start}}} \frac{a_{i\text{-start}}}{a_t}
$$

where

- $a_{\text{dec}} \rightarrow$ photons decoupling, $z_{\text{dec}} \simeq 1070, T_{\text{dec}} \simeq 3 \cdot 10^3$ K = 0.2 eV
- $a_{\text{rh}} \rightarrow$ reheating phase, $T_{\text{rh}} = T_{\text{GUT}} \simeq 10^{14}$ GeV
- $a_{i\text{-end}} \rightarrow$ end of inflation
- $a_{i\text{-start}} \rightarrow$ beginning of inflation

We can assume the sudden reheating approximation ($a_{\text{rh}} \simeq a_{i\text{-end}}$) and the standard value of e-folding number for inflation $N \equiv \ln(a_{i\text{-end}}/a_{i\text{-start}}) = 63$. Then increase of the scale factor forms the final state till present value assumes

$$
\frac{a_{\text{today}}}{a_t} \simeq (1 + z_{\text{dec}}) \cdot \frac{T_{\text{GUT}}}{T_{\text{dec}}} \cdot e^N \cdot \frac{a_{i\text{-start}}}{a_t} \simeq 10^{56}.
$$

We had assumed here that $a_{i\text{-start}}/a_t \simeq 10^2$, this value can be obtained from numerical simulations like these in Ref. [14]. Now we can return to equation (52) and then calculate the maximal frequency of produced gravitons. From the right panel in Fig. 4 we can see that in the vicinity of $\tau \sim -6$ we have the transition from positive to negative values of $\Gamma$. So as we can see for some $10 < k_{tr} < 1000$ we have the transition from the adiabatic to the super-adiabatic regime. From the numerical investigation we obtain $k_{tr} \simeq 500$. In fact the function $\Gamma$, for small values of $\tau$, is always slightly below zero even for greater values of $k$ than $k_{tr}$. But we assume that this effect is negligible. In fact higher values of $k$ easily reach the transplanckian scales and it is not clear that we should trust the standard physics in this regime. The wave number $k_{tr}$ corresponds roughly to the scales $a_s$. So the value of $k_{tr}$ corresponds to $k_{tr} = (a_*/a_t)k_{tr} \simeq 250$ in the final state $a_t(\tau = -1) = 3.912l_{Pl}$. Applying equation (52) we obtain the maximal frequency for the present epoch $\nu_{\text{max}} \simeq 2 \cdot 10^{-12}$ Hz. This value corresponds to the scales $\lambda_{\text{min}} \simeq 5$ kpc. It
is instructive to consider the model without inflation. In this situation the maximal frequency of the relic gravitons would be \( \nu_{\text{max}} \approx 2 \cdot 10^{15} \) Hz, what is extremely huge number. In fact it is possible that GUT energy scale and inflation cover each other in some place. It was somehow one of the motivation to introduce inflation to solve the problem of topological defects. In the case when the GUT scale occurs after the reheating the problem of topological defects must be solved in a different way. We mention this problem to show that it is possible that the value \( a_{\text{today}}/a_1 \) can be lower than calculated before.

After this analysis we can return now to equation (51). We need to use the definition of the quantum correction \( D \) and effective mass \( m_{\text{eff}}^2 \) in the quantum regime. It is also useful to rescale the conformal time and introduce \(-\eta = -\tau + \beta\). We will back later to the previous definition because an additional degree of freedom \( \beta \) is necessary to fit properly the boundary solutions with numerical one. Equation (51) takes the form

\[
\frac{d^2}{d\eta^2} f(k, \eta) + \left[ D_\nu \xi^n(-\eta)^{np} k^2 - \frac{p(p-1)}{\eta^2} \right] f(k, \eta) = 0
\]

(55)

and the general solution in terms of Bessel functions have the form

\[
f(k, \eta) = C_1 \sqrt{-\eta} J_{|\nu|}(x) + C_2 \sqrt{-\eta} Y_{|\nu|}(x)
\]

(56)

with

\[
x = k \frac{2\sqrt{D_\nu \xi^n}}{|2 + np|} (-\eta)^{(2+np)/2},
\]

(57)

\[
\nu = -\frac{\sqrt{1 + 4p(p-1)}}{2 + np}.
\]

(58)

With the use of the Wronskian condition (50) we can rewrite the solution (56) to the form

\[
f(k, \eta) = \sqrt{\frac{\pi}{2|2 + np|}} \sqrt{-\eta} \left[ D_1 H_{|\nu|}^{(1)}(x) + D_2 H_{|\nu|}^{(2)}(x) \right]
\]

(59)

where we introduced Hankel functions defined as

\[
H_{|\nu|}^{(1)}(x) = J_{|\nu|}(x) + iY_{|\nu|}(x)
\]

(60)

\[
H_{|\nu|}^{(2)}(x) = J_{|\nu|}(x) - iY_{|\nu|}(x).
\]

(61)

and the constants \( D_1 \) and \( D_2 \) enjoy the relation \( |D_1|^2 - |D_2|^2 = 1 \). To fix values of the constants \( D_1 \) and \( D_2 \) we must consider the high energy limit, namely \( x \gg 1 \). In this limit the Bessel functions behave as follow

\[
J_{|\nu|}(x) \to \sqrt{\frac{2}{\pi x}} \cos \left( x - \frac{|\nu|\pi}{2} - \frac{\pi}{4} \right),
\]

(62)

\[
Y_{|\nu|}(x) \to \sqrt{\frac{2}{\pi x}} \sin \left( x - \frac{|\nu|\pi}{2} - \frac{\pi}{4} \right),
\]

(63)

what give us \( H_{|\nu|}^{(1)}(x) \to \sqrt{2/(\pi x)} \exp[ix - i|\nu|\pi/2 - i\pi/4] \) and \( H_{|\nu|}^{(2)}(x) \to \sqrt{2/(\pi x)} \exp[-ix + i|\nu|\pi/2 + i\pi/4] \).

Classically the limit \( x \gg 1 \) corresponds to advanced solution \( e^{-i k \tau}/\sqrt{2k} \) in the Minkowski spacetime. Generally the limit obtained here differs from the classical one but can be restored taking \( t = 2 \). Then to obtain the proper high energy limit we must choose \( D_2 = 0 \) and \( D_1 = \exp[i|\nu|\pi/2 + i\pi/4] \). Applying evaluated values of \( D_1 \) and \( D_2 \) to the solution (59) we finally obtain mode functions for the initial state

\[
f_i(k, \tau) = N \frac{1}{\sqrt{k}} \sqrt{-k\tau + k\beta} H_{|\nu|}^{(1)}(x)
\]

(64)

\[
g_i(k, \tau) = N \sqrt{k} \sqrt{-k\tau + k\beta} \left[ -\frac{1}{2} \frac{H_{|\nu|}^{(1)}(x)}{2 - k\tau + k\beta} - \frac{2 + np}{|2 + np|} D_\nu \xi^n(-\tau + \beta) \frac{i\pi}{x} \right]
\]

(65)

where

\[
N = e^{i(|\nu|\pi/2 + \pi/4)} \sqrt{\frac{\pi}{2|2 + np|}}
\]

(66)
The functions $g_i(k, \tau)$ were calculated from relation $f(k, \tau)' = g(k, \tau)$ shown earlier. We had used also the expression for derivative of the Hankel functions in the form

$$\frac{dH^{(1)}_{|\nu|}}{dx} = \frac{|\nu|}{x} H^{(1)}_{|\nu|}(x) - H^{(1)}_{|\nu|+1}(x).$$ \hfill (67)

Similar investigations lead to the expression for the mode functions for the final state. We must remember that it is however not only a simple set $l = 2$ but also the change of the solution for the scale factor to this expressed by (22). In this case we obtain

$$f_f(k, \tau) = e^{-i \frac{\pi}{4} + ik\zeta} \sqrt{\frac{\pi}{4k}} \sqrt{k\tau + k\zeta} H^{(2)}_{0}(k\tau + k\zeta),$$ \hfill (68)

$$g_f(k, \tau) = e^{-i \frac{\pi}{4} + ik\zeta} \sqrt{\frac{\pi}{4k}} \sqrt{k\tau + k\zeta} \left[ \frac{1}{k\tau + k\zeta} H^{(2)}_{0}(k\tau + k\zeta) - H^{(2)}_{1}(k\tau + k\zeta) \right].$$ \hfill (69)

Now we are ready to consider the creation of the gravitons during the transition from some initial to final states. The initial vacuum state $|0_i\rangle$ is determined by $\hat{a}_k |0_i\rangle = 0$, where $\hat{a}_k$ is the initial annihilation operator for $\tau_i$. The relation between annihilation and creation operators for the initial and final states is given by the Bogoliubov transformation

$$\hat{b}_k = B_+(k)\hat{a}_k + B_-(k)^*\hat{a}^\dagger_{-k},$$ \hfill (70)

$$\hat{b}^\dagger_k = B_+(k)^*\hat{a}^\dagger_k + B_-(k)\hat{a}_{-k}$$ \hfill (71)

where $|B_+|^2 - |B_-|^2 = 1$. Because we are working in the Heisenberg description the vacuum state does not change during the evolution. It results that $\hat{b}_k |0_i\rangle = B_-(-k)^*\hat{a}^\dagger_{-k} |0_i\rangle$ is differ from zero when $B_-(-k)^*$ is a nonzero function. This means that in the final state graviton field considered is no more in the vacuum state without particles. The number of produced particles in the final state is given by

$$\bar{n}_k = \frac{1}{2} \langle 0_i | \hat{b}_k^\dagger \hat{b}_k + \hat{b}^\dagger_{-k} \hat{b}_{-k} | 0_i \rangle = |B_-(k)|^2.$$ \hfill (72)

Using relations (46) and (47) and the Bogoliubov transformation (70) and (71) we obtain

$$B_-(k) = \frac{f_f(k, \tau_i)g_f(k, \tau_f) - g_f(k, \tau_i)f_f(k, \tau_f)}{f_f^*(k, \tau_f)g_f(k, \tau_f) - g_f^*(k, \tau_f)f_f(k, \tau_f)} = i \left[ f_i(k, \tau_i)g_f(k, \tau_f) - g_i(k, \tau_i)f_f(k, \tau_f) \right]$$ \hfill (73)

$$B_+(k) = \frac{f_i(k, \tau_i)g^*_f(k, \tau_f) - g_i(k, \tau_i)f^*_f(k, \tau_f)}{f_f(k, \tau_f)g^*_f(k, \tau_f) - g_f(k, \tau_f)f^*_f(k, \tau_f)} = -i \left[ f_i(k, \tau_i)g^*_f(k, \tau_f) - g_i(k, \tau_i)f^*_f(k, \tau_f) \right]$$ \hfill (74)

where simplifications come from the Wronskian condition (50). In the calculations we set $\tau_i = \tau_1 = -20$ and $\tau_f = \tau_2 = -1$. These boundaries fully cover the region of gravitational waves creation. The energy density of gravitons is given by

$$d\rho_{gw} = 2 \cdot \hbar \omega \cdot \frac{4\pi\omega^2 dv}{(2\pi c)^3} \cdot |B_-(k)|^2.$$ \hfill (75)

where we used definition (72). The expression for the parameter $\Omega_{gw}$ defined by (25) takes now the form

$$\Omega_{gw}(\nu) = \Omega_0 \cdot \nu^4 \cdot \bar{n} \left[ k = \nu \cdot 2\pi a_t \cdot \left( \frac{a_{today}}{a_t} \right) \right]$$ \hfill (76)

where

$$\Omega_0 = \frac{\hbar c 16\pi^2}{c^4 \rho_c} = \frac{16\pi^2 \cdot 197.3 \cdot 10^{-15} \text{[MeV} \cdot \text{m}]}{34 \cdot 10^{12} \text{[m}^2/\text{s}^4] 1.05 \cdot 10^{-6} \cdot h_G^2 \text{[GeV/cm]}^2} = 3.66 \cdot 10^{-2} \cdot 10^{-49} \text{[Hz}^{-4}].$$ \hfill (77)

In the calculations we set present value of the Hubble factor for $h_0 = 0.7$. In Fig. 5 we show spectrum calculated with formula (76). The obtained spectrum is extremely weak in the present epoch. The reason of this tiny amount of the background gravitons is the presence of the standard inflationary phase. The super-inflationary phase is placed before the inflation so the energy of gravitons decreases about $10^{27}$ times during this further phase. To see better how...
FIG. 5: Spectrum of relic gravitons for the model with $j = 100$ and $l = 3/4$. Frequency scale in Hertz.

FIG. 6: Spectrum of relic gravitons for the model without inflation. Frequency scale in Hertz.

presence on the inflation affect this spectrum we show in Fig. 5 the spectrum of relic gravitons in the model without the inflationary phase.

It is clear that in such a model amount of relic gravitons would be extremely large. As we mentioned before it is possible that GUT energy scales cover partially with the inflation. In this situation the present amount of the relic gravitons would be higher than this in Fig. 5 and reaches to higher energies. For the present state we do not know the duration of the inflationary phase exactly. To estimate this value it is necessary to measure the spectrum of both scalar and tensor parts of primordial fluctuations produced during the standard inflation. For the present day we know only the contribution from the scalar part. The further generation of CMB telescopes is needful to improve the knowledge the properties of inflation. From our calculation we can see however that the inflationary phase is necessary. Without the inflation after the super-inflation the present amount of gravitons would be easily in reach of present observational skills. From this point of view we have found the next motivation to support the inflationary model.
In summary, we have calculated the spectrum of gravitons produced during the super-inflationary phase induced by Loop Quantum Gravity effects. In the calculations we considered inverse-volume corrections to the dynamics and to the equation for the tensor modes. We have solved analytically equation for the tensor modes in the quantum and classical regimes. Both solutions we had matched by numerical solution for background dynamics. We have obtained spectra of relic gravitons for the models considered. In the first model we assumed the presence of the inflationary phase after the super-inflation. In that case we obtained presently a negligible amount of relic gravitons. However in the second model without inflation the present amount of graviton background would be unnaturally high. This results state that the period of inflation after the super-inflation is necessary to avoid the problem of relic gravitons. Nowadays the main motivation to introduce the inflationary phase comes from ability to creation of fluctuations. Our investigations based on loop quantum cosmology support the inflationary model.

When the amount of produced gravitons is high, possible nonlinear effects can occur in the result of out from linear regime. This can potentially lead to the new effects and to the limitation of the approach used in the present paper. We address this issue to the future investigations.

Results obtained in this work differ from our previous investigations [8]. The difference comes mainly from different assumptions about the evolution of the Universe after the super-inflation. The effects of corrections to the equation for tensor modes are here less important. The previous results correspond to the situation when inflation and GUT energy scales cover each other rather than to the case of very short inflation. In this paper we have considered both models agreeing with the present paradigm and its modification.
