ZIP1+ fibroblasts protect lung cancer against chemotherapy via connexin-43 mediated intercellular Zn2+ transfer

Lung cancer is the leading cause of cancer death worldwide1. Chemotherapy, radiotherapy, targeted biological therapy, and in recent years immunotherapy are central treatment options for lung cancer patients. Chemotherapy failure is a major challenge in the clinical treatment of lung cancer, and better therapeutic strategies are urgently needed2. Chemotherapy is often prescribed to patients with early-stage cancer as an adjunct therapy for surgery, or to patients with advanced cancer to suppress tumour formation3. After an initial response, relapse and metastasis commonly occur due to drug resistance, and patients usually succumb to the disease. Unfavourable tumour–stroma crosstalk may contribute to the chemoresistance of lung cancer by modulating the extracellular matrix, generating an immunosuppressive niche, and promoting cancer stem cells4. When treated with drugs, stromal fibroblasts can adapt to chemotherapy-induced damage and communicate with cancer cells to affect drug responses5–7. Understanding fibroblast-tumour communication will undoubtedly be helpful for the improvement of lung cancer therapy.

Cancer-associated fibroblasts (CAFs) are heterogeneous stromal cells that are implicated in lung cancer chemoresistance8–10. Long-range interactions by secreting factors or exosomes between CAFs and tumours have been extensively studied which impact tumour progression and therapy responses11–13. However, short-range interactions, including cell–cell contacts between CAFs and tumours, have rarely been described14. We and others have reported that fibroblasts can directly link with tumour cells to lead to their metastasis15. A previous study reported that CAFs may form gap junctions with lung cancer cells to exchange metabolites16. Gap junctions are intercellular communication channels that connect neighbouring cells, allowing the passage of small molecules (<1000 Da)17. The membrane protein connexin forms a hexameric structure as a connexon that docks with a
corresponding connexon on a neighbouring cell to form a gap junction channel\(^1\). It has been reported that brain metastases of lung cancer cells link astrocytes by gap junctions and activate astrocytes by cGAMP transfer, thereby supporting tumour growth and chemoresistance\(^4\). However, the regulatory mechanisms of fibroblast–cancer cell intercellular communication by gap junctions during chemotherapy is still unknown.

Here, we show ZIP\(^1\) CAF subset is enriched in lung cancer models after chemotherapy and actively transfers Zn\(^2+\) to cancer cells, promoting ABCB1-mediated chemoresistance. In this study, we use single-cell RNA sequencing (scRNA-seq) to examine the adaptations of fibroblasts after chemotherapy in a mouse lung cancer model. We identify a zinc-transporter positive (ZIP\(^1\)) CAF subset, which is enriched in mouse lung cancer treated with chemotherapy; Zirc and Ir1t-like protein 1 (ZIP1) (also known as SLC39A1) is a zinc transporter that imports Zn\(^2+\) from the extracellular space\(^8\). Unexpectedly, we find that ZIP\(^1\) fibroblasts interconnect cancer cells via gap junctions by upregulating connexin-43 (CX43). Furthermore, ZIP\(^1\) fibroblasts act as Zn\(^2+\) reservoirs to absorb and transfer Zn\(^2+\) to lung cancer cells, inducing ABCB1-mediated drug extrusion. Finally, the contribution of ZIP\(^1\) fibroblasts to chemoresistance in lung cancer cells is studied. Our findings provide insights into fibroblast–tumour short-range interactions and have important implications for lung cancer therapy.

**Results**

**ZIP\(^1\) fibroblasts are enriched in lung mouse lung cancer after chemotherapy**

We aimed to study the early-stage adaptation of CAFs to chemotherapy-induced damage. Considering that lung cancer patients receiving chemotherapy are usually at advanced stages with distant metastases, the ectopic tumour model might facilitate the exploration of potential origin-nonspecific changes in CAFs. Lewis lung carcinoma (LLC) cells were subcutaneously transplanted into C57BL/6 mice with ubiquitous enhanced green fluorescent protein (EGFP) expression. The established tumours (~100 mm\(^3\)) were treated with doxorubicin (DOX) three times every 2 days. Two days after treatment cessation, EGFP\(^+\) CD45\(^-\) CD4\(^+\) CD11b\(^+\) tumour stromal cells, excluding immune cells (CD45\(^+\)), were isolated and sorted for scRNA-seq (Fig. 1a, b, Supplementary Fig. 1a, b). Eight stromal cell clusters were identified (Fig. 1c, d, Supplementary Table 1; Supplementary Fig. 1c–e). Cluster 5 cells are typical endothelial cells that express Pecam1, Cldn5 and Plugp. Cluster 4 cells express genes encoding monocyte markers (CD11b encoded by Itgam, Lycz2, CD14) and fibroblast markers (Dcn, Fln1, Sparc and Opn encoded by Spp1), implying that they are likely bone marrow-derived fibrocytes\(^8\). A recent study also identified fibroblasts expressed both fibroblast and macrophage markers and proposed macrophage–myofibroblast transition mechanism for the generation of these cells\(^15\). Clusters 0–3 (>95% of the cells) and 6–7 were non-epithelial, non-endothelial, and non-hematopoietic fibroblasts, expressing fibroblast markers (Dcn, Fln1, Sparc and Opn). Interestingly, we found that the Cluster 0 fibroblast subset highly expressed Zip1 (encoded by slc39a1) (Fig. 1c, d, Supplementary Table 1), a Zn\(^2+\) transporter that imports Zn\(^2+\) from the extracellular space to the cytosol\(^8\). ZIP1 belongs to the solute carrier family SLC39, which is responsible for maintaining cytosolic zinc concentrations\(^8\). The human SLC39 family includes members ZIP1–14, among which ZIP4, ZIP6, ZIP7, ZIP10, and ZIP14 have been implicated in cancer progression, cachexia, and immunodeficiency by tuning cellular Zn\(^2+\) and zinc-associated signalling\(^8\). Compared to tissues from untreated control mice, Cluster 0 ZIP\(^1\) CAF cells were increased in tumours from DOX-treated mice, whereas other CAF subsets were decreased (Fig. 1e, f).

The biological function of each CAF subset was explored (Fig. 1g, Supplementary Fig. 1f, h), which are representative myofibroblasts (myCAF23). The “myogenesis” signature was also active in Cluster 2 CAFs (Fig. 1g). Notably, Cluster 2 CoUat\(^+\) CAFs expressed Nunt, which encodes nicotinamide N-methyltransferase (Supplementary Fig. 1g), which has been associated with a “hypomethylation” phenotype of CAFs (metCAF)\(^8\). Cluster 3 Hmgb2\(^+\) CAFs expressed proliferation marker genes Cdki, Mki67, Ccn2a, Ccnb1 and Ccnb2 (Supplementary Table 1), and enriched the pathways “mitotic spindle,” “G2M checkpoint” and “Myc targets” (Fig. 1g). No specific positive markers were identified for Cluster 1 CAFs (Supplementary Table 1). Cluster 0 Zip1\(^+\) CAFs expressed the marker genes Notch2 and Zip1 (Supplementary Table 1), which are associated with embryonic development (Supplementary Data 1), implying a developmental CAF phenotype\(^23\). Notch2 has been reported to be critical for the maintenance of cell stemness in hematopoietic cells and neural stem cells\(^27\). Cluster 0 Zip1\(^+\) CAFs moderately expressed Opr (Supplementary Fig. 1h), which labels universal fibroblasts\(^27\). We further applied the cNMF algorithm to the cells of Cluster 0-3 to identify gene expression programmes (GEP) in these cells\(^23\). We identified the top 100 genes for each GEP (Supplementary Table 2) and performed a GO (Gene Ontology) analysis to explore the function of each GEP (Supplementary Data 2). Relating to the clusters and programmes, we found that of the four clusters, Cluster 0 was strongly enriched for developmental GEP, Cluster 1 was strongly enriched for metabolic GEP, Cluster 2 was strongly enriched for matrix GEP\(^3\), and Cluster 3 was strongly enriched for proliferating GEP\(^4\), further supporting that they are distinct clusters (Supplementary Fig. 1i). Although there were no specific markers, Cluster 1 highly expressed metabolism-related genes, such as Gchfr, Mf1, and Cox5u, that were shared with other clusters (Supplementary Fig. 1j). To compare pathway activity among the seven clusters, we used PROGENY to estimate the activity of the 14 pathways\(^23\). The PI3K signalling pathway was active in Cluster 0 Zip1\(^+\) CAFs, while the TGF\(\beta\) signalling pathway was active in Cluster 6 and 7 myofibroblasts, the JAK-STAT signalling pathway was active in Cluster 4 fibrocytes, and the VEGF signalling pathway was active in Cluster 2 (Supplementary Fig. 1k). It has been reported that TGF\(\beta\) stimulates myofibroblast phenotype and IL-1 (activating JAK-STAT) promotes inflammatory fibroblasts\(^28\). Therefore, Cluster 0 Zip1\(^+\) CAFs might be driven by a distinct PI3K signalling pathway compared to other clusters.

RNA velocity analysis was performed to evaluate the fate of fibroblasts. Two strong differentiation routes were observed in the DOX group. One route is from Cluster 0 to Cluster 2, and the other is within Cluster 0 (Fig. 1h), which implies that Cluster 0 cells tend to partially differentiate into metCAF\(^+\) and partially retain their phenotype. We evaluated gene upregulation in cluster transition. For example, Pld2, Nunt and CoUat were upregulated in transition from Cluster 0 to Cluster 2, while Spry2, Mt2 and Mt1 were upregulated in transition within Cluster 0 (Supplementary Fig. 1i–o, Supplementary Table 3). Immunostaining confirmed that DOX treatment elevated the number of ZIP\(^1\) fibroblasts compared to control LLC tumours (Supplementary Fig. 1p, q). In another transplanted tumour model of pancreatic cancer Pan02, we also observed the presence of ZIP\(^1\) fibroblasts (Supplementary Fig. 1r), implying that ZIP\(^1\) fibroblasts may be a common fibroblast subpopulation. Moreover, in human lung adenocarcinoma-associated fibroblasts (hCAF\(^+\)) isolated from lung adenocarcinoma with neoadjuvant chemotherapy, ZIP\(^1\) fibroblasts were present (Supplementary Fig. 1s).

**ZIP\(^1\) fibroblasts interconnect lung cancer cells by upregulating CX43**

These RNA velocity results imply that Cluster 0 may contain two subgroups of fibroblasts. We tuned the resolution of single-cell RNA analysis and separated Cluster 0 ZIP\(^1\) fibroblasts into two subgroups (Cluster CA0 and CA1) (Fig. 2a). Compared with the PBS group, CA0 was the most increased cell subset, followed by CA1, in the DOX group
CA0 and CA1 highly expressed Zip1+ fibroblasts in LLC tumours following DOX treatment. a Schematic of experimental design for single-cell RNA sequencing (scRNAseq) of stromal fibroblasts after chemotherapy in LLC tumour transplanted into C57BL/6-EGFP mice. b Tumour growth curve of LLC tumours treated with or without doxorubicin (DOX) as described in a. n = 3 for each group. (Fig. 2a, b). CA0 and CA1 highly expressed Zip1+ while weakly expressing the other zinc transporters (Supplementary Fig. 2a). In addition, CA0 cells expressed higher S100a4 when compared to CA1 cells (Supplementary Fig. 2b). To discriminate the specific functions of CA0 and CA1, each subtype was compared with all other subtypes within CA0−7 and pathway enrichment was performed. The results showed that CA0 enriched “gap junction” while CA1 enriched “cell cycle” and “apoptosis” (Fig. 2c).

Next, we examined whether the expression of ZIP1 in fibroblasts affects gap junction protein expression. Connexin-43 (CX43)
expression has been observed in fibroblasts and engages in myocyte–fibroblast coupling\textsuperscript{31,32}. The results showed that overexpression of ZIP1 in hCAF increased the expression of CX43 (Fig. 2d, Supplementary Fig. 2c). Moreover, overexpression of ZIP1 in prostate cancer-associated fibroblasts (PCCAFs) and mouse embryonic fibroblasts (MEFs) increased the expression of CX43 (Fig. 2e, Supplementary Fig. 2d, e), implying that the regulation of CX43 by ZIP1 is independent of fibroblast origin. Conversely, knockdown of Zip1 in MEFs decreased the expression of CX43 (Fig. 2f, Supplementary Fig. 2f). To further confirm the ZIP1-dependent CX43 expression in lung CAF, we transplanted LLC-GFP-luc tumour cells into Zip1\textsuperscript{+/+}, Zip1\textsuperscript{+/-} and Zip1\textsuperscript{-/-} mice. On day 22, the expression of CX43 on CD45\textsuperscript{-}CD31\textsuperscript{-}GFP\textsuperscript{-}CAF was analysed by flow cytometry. CD45\textsuperscript{-}CD31\textsuperscript{-}GFP\textsuperscript{-} CAF from Zip1\textsuperscript{+/-} mice expressed higher levels of...
Fig 2 | ZIP1+ fibroblasts interconnect cancer cells with gap junctions by upregulating CX43. a UMAP plot showing 12 cell subsets in PBS group, DOX group and their combined. b Bar plots showing the percentages of cells in each subset with PBS and DOX treatment. c Gene set variation analysis of KEGG signalling pathway terms within the 8 fibroblast subsets (CAO−7, d. e ZIP1 and CX43 expression in d human lung adenocarcinoma-associated fibroblasts (hCAF) and e prostate-cancer-associated fibroblast (PCCAF) transfected with control (mock) or ZIP1-overexpression vector (ZIP1). Representative results from four (d), three (e, ZIP1) or five (e, CX43) independent experiments are shown. CX43 expression in mouse embryonic fibroblasts (MEFs) transfected with control (siCtrl) or Zip1-silencing (siZip1) siRNA. A representative result from five independent experiments is shown. β-actin was used as control. The samples derived from the same experiment and blots were processed in parallel (e, f). CX43 expression on the cell surface of Zip1+/+, Zip1−/− and Zip1−/+ CAFs. Single-cell suspensions of LLC-GFP-luc tumours from indicated mice were analysed by FACS on day 22. 

Next, we examined whether CX43 on CAFs could physically interact with CX43 in tumour cells. We ectopically expressed CX43-GFP in PCCAFs and CX43-RFP in A549 cells, which were physically in contact with each other (Supplementary Fig. 2i). Furthermore, CX43-GFP co-immunoprecipitated with CX43-RFP in lysates of PCCAF-CX43-GFP and A549-CX43-RFP co-culture (Fig. 2h), indicating a CX43-CX43 physical interaction between CAFs and tumour cells. The results further showed that functional gap junctions were formed between A549 tumour cells and hCAFs, as indicated by the transfer of the fluorescent dye calcein from fibroblasts to tumour cells, which could be impaired by heptanol, the gap-junction uncoupler (Fig. 2i). In co-cultures, ZIP1-overexpressing hCAFs and PCCAFs were more efficient in transferring calcein to A549 tumour cells than to control fibroblasts (Fig. 2j, Supplementary Fig. 2j). Upon CX43 knockdown, the transfer of calcein by hCAFs was impaired (Supplementary Fig. 2k). These results demonstrated that ZIP1+ fibroblasts form efficient gap junctions between tumour cells through the upregulation of CX43.

ZIP1+ fibroblasts act as a Zn2+ reservoir and transfer Zn2+ to cancer cells

Interconnections between fibroblasts and cancer cells via gap junctions enable electrical and metabolic exchanges between cells. Considering Zn2+ as a substrate of ZIP1, we explored the possible shuttle transport of Zn2+ between the two cells. The results showed that after DOX treatment, labile Zn2+ levels in the tumour interstitial fluid increased (Fig. 3a). In addition, large necrosis was observed in tumours treated with DOX (Fig. 3b). Thus, we suspected that cell death during chemotherapy may have released intracellular Zn2+ into the interstitial space. Notably, the fluorescence of DOX in the culture medium may interfere with the detection of Zn2+ using the probe FluoZin3. To validate and generalise the above speculation, we used extreme temperatures (95 °C, −80 °C) and paclitaxel to induce cell death in LLC cells. When tumour cells were treated as described above, Zn2+ was released from dying tumour cells, regardless of the type of treatment (Fig. 3c, d).

The results further showed that CAFs were able to absorb Zn2+ released by dying cancer cells treated with paclitaxel (Fig. 3e), and the absorption was proportional to the extracellular doses of Zn2+ (Fig. 3f). The deficiency of Zip1 in MEFs or mouse LLC tumour CAFs (mCAFs) reduced the uptake of Zn2+ from the extracellular space (Fig. 3g, Supplementary Fig. 3a). Overexpression of Zip1 in hCAFs and PCCAFs increased the uptake of Zn2+ from the extracellular space (Fig. 3h, Supplementary Fig. 3b).

Next, we examined whether fibroblasts could deliver labile Zn2+ to cancer cells via the gap junctions. First, labile Zn2+ in CAFs and tumour cells was determined. The results showed that hCAFs maintained a higher labile Zn2+ gradient than A549 tumour cells under both basal (Fig. 3i) and high Zn2+ conditions (30 μM) (Supplementary Fig. 3c). Co-cultured with hCAFs increased labile Zn2+ in A549 cells, which could be blocked by heptanol or PTEN (a Zn2+ chelator) pre-treatment of hCAFs to reduce the Zn2+ gradient (Fig. 3j). In Hanks’ balanced salt solution (HBSS, with CaCl2), hCAFs overexpressing ZIP1 effectively transferred Zn2+ to A549 cells, and this transfer was blocked by heptanol (Fig. 3k). Notably, control hCAFs could not transfer Zn2+ to tumour cells under these conditions (Fig. 3k). ZIP1+ MEFs, but not ZIP1−/− or ZIP1−/+ MEFs, significantly enhanced Zn2+ levels in LLC (Fig. 3l). These results demonstrated that ZIP1+ fibroblasts can act as Zn2+ reservoirs to absorb and transfer Zn2+ to tumour cells through gap junctions.

Zn2+ mediates upregulation of CX43 through activating AKT

Because Zn2+ can be absorbed by fibroblasts from the extracellular space, we investigated whether Zn2+ is involved in the regulation of CX43. Interestingly, the results showed that Zn2+ stimulated the upregulation of CX43 and activation of pAKT in a dose-dependent manner in mCAFs and hCAFs (Fig. 4a, Supplementary Fig. 4a, b). This is consistent with the above results showing enrichment of PI3K/AKT signalling in ZIP1+ cells (Fig. 1g). The addition of Zn2+ led to a reduction in PTEN (an endogenous inhibitor of the PI3K/AKT pathway) in mCAFs (Fig. 4b, Supplementary Fig. 4c). Inhibition of AKT with LY294002 impaired Zn2+-induced upregulation of CX43 in mCAFs (Fig. 4c, Supplementary Fig. 4d). Compared to ZIP1−/− MEFs, in ZIP1+ MEFs AKT was activated and PTEN was downregulated (Fig. 4d, Supplementary Fig. 4e).

The results demonstrated that Zn2+ could be transferred to cancer cells by fibroblasts, and the regulation of CX43 in cancer cells by Zn2+ was studied. Interestingly, co-culture of LLC-GFP-luc cells with mCAFs resulted in higher expression of CX43 than that in mono-cultured tumour cells, which was attenuated by heptanol or by pretreatment of fibroblasts with PTEN (Fig. 4e, Supplementary Fig. 4f). When ZnCl2 was directly added to LLC cell cultures, intracellular labile Zn2+ increased in a dose-dependent manner (Supplementary Fig. 4g). Zn2+ stimulation resulted in the time-dependent and dose-dependent elevation of CX43 expression in tumour cells (Fig. 4g, h, Supplementary Fig. 4h). Co-culture with ZIP1+ MEFs, but not with ZIP1− MEFs, induced CX43 expression in the LLC-GFP-luc cells (Fig. 4h). In accordance with the above results, CX43 expression was higher on the cell surface of ZIP1−/− MEFs than in ZIP1+ MEFs (Fig. 4h). These results suggest that Zn2+ derived from fibroblasts further increases gap junction formation by upregulating CX43 in cancer cells.
**Zn²⁺ induces ABCB1-mediated drug extrusion of cancer cells**

The effect of Zn²⁺ derived from fibroblasts on the tumour response to drugs was studied. We first noted that Zn²⁺ uptake by tumour cells was suppressed by chemotherapy treatment (Fig. 5a), implying that they might need Zn²⁺ supplementation from fibroblasts under stress. DOX treatment-induced drug accumulation (determined by DOX fluorescence in individual cells) and DNA damage (indicated by phosphorylated histone γ-H2AX expression) in tumour cells, which could be attenuated by the addition of fibroblasts to the cultures (Fig. 5b). Interestingly, the addition of heptanol or pretreatment of fibroblasts...

with TPEN reversed these protective effects (Fig. 5b). ABCB1 is a multidrug resistance protein that exports multiple drugs, including DOX, from cells33, whose inhibition elevated drug accumulation in tumour cells (Supplementary Fig. 5a). Co-culture of LLC-GFP-luc cells with mCAF-induced ABCB1 expression in tumour cells, which was reduced by heptanol or TPEN pretreatment (Fig. 5c, Supplementary Fig. 5b). When DOX was combined with TPEN or heptanol, the protection of tumour cells by mCAFs was inhibited (Fig. 5d). These results also imply that the resistance of tumour cells to drugs may not be limited to DOX. To examine the resistance of tumour cells to alternative substrates of ABCB1, we combined paclitaxel with TPEN to treat the tumour cells. We added a relatively low level of TPEN (0.3 M) to reduce tumour...
Fig. 5 | Labile Zn\textsuperscript{2+} induces ABCB1-mediated drug extrusion. a Zn\textsuperscript{2+} uptake by LLC cells treated with paclitaxel (PTX). A representative result from three independent experiments is shown. Two-way ANOVA test for curve comparison. Source data are provided as a Source Data file (a–k).

A tetracycline (Tet)-off expression system was used to control the expression of Zip1 in mCAFs. In this system, Zip1 was overexpressed under normal conditions but was repressed when tetracycline was added. Although the shutdown of Zip1 expression by tetracycline in mCAF did not significantly affect tumour growth (Supplementary Fig. 6d), the overexpression of Zip1 in mCAFs promoted tumour growth compared to mCAF-mock (Fig. 6h). To further validate that Zip1 fibroblast-dependent upregulation of the multidrug resistance protein ABCB1 expression in tumour cells contributed to chemoresistance, we used paclitaxel combined with doxycycline to treat the co-injected tumours. When tumours were treated with paclitaxel, repression of Zip1 by doxycycline was observed in mCAF-sensitised tumours to chemotherapy (Fig. 6h).

S100A4 increases Zip1 expression in fibroblasts

We sought to determine how chemotherapeutic treatment-enriched Zip1 fibroblasts. The results showed that DOX treatment in vitro reduced Zip1 expression in mCAFs (Fig. 7a, b, Supplementary Fig. 7a, b). Therefore, we suspected that chemotherapeutic-induced secretory factors might play a role in the regulation of Zip1 expression in fibroblasts. Other’s and our own previous studies demonstrated that S100A4 often increases in tissues under stress\textsuperscript{18–19}. In vitro, we found that DOX treatment increased the release of S100A4 into the supernatants by tumour cells (Fig. 7c, Supplementary Fig. 7e). Compared to the control medium, the culture medium collected from DOX-treated tumour cells upregulated Zip1 expression in fibroblasts, which could be reversed by anti-S100A4 antibody (Fig. 7d, Supplementary Fig. 7d). S100A4 stimulation upregulated Zip1 expression in fibroblasts in a dose- and time-dependent manner (Fig. 7e, f, Supplementary Fig. 7e, f). Downstream NF-κB (p65), AKT, and p38 were activated by S100A4 in fibroblasts, and their inhibitors improved S100A4-mediated upregulation of Zip1 (Fig. 7g–i, Supplementary Fig. 7g–i). RAGE and TLR4 are receptors for S100A4\textsuperscript{34–36}. The upregulation of Zip1 by S100A4 was attenuated by both RAGE inhibitor (FPS-ZM1) and TLR4 inhibitor (TLR4-IN-C34) (Fig. 7j, Supplementary Fig. 7j). These results suggest that S100A4 might bind to RAGE/TLR4, activate NF-κB (p65), AKT, and p38, and promote the expression of Zip1 in fibroblasts (Fig. 7k). Furthermore, we confirmed that extracellular S100A4 levels increased in LLC-GFP-luc tumour tissues after DOX treatment (Fig. 7l). These results suggested that the increase in S100A4 levels after chemotherapy may be responsible for the enrichment of Zip1 fibroblasts.

ZIP1\textsuperscript{high} fibroblasts predict chemoresistance in lung cancer patients

To further explore the presence of Zip1 fibroblasts in human lung cancer, we analysed a previously published scRNA-seq dataset of human lung adenocarcinomas\textsuperscript{19}. Datasets of eight primary lung adenocarcinomas were downloaded and analysed. A total of 554 fibroblasts were identified and classified into four clusters (CH0–3) (Supplementary Fig. 8a, b, Supplementary Data 3). Zip1 was highly
expressed in the CH0, 1, 3 clusters (Supplementary Fig. 8c, d), among which CH0 was corresponding to a developmental phenotype that enriched developmental pathways including "embryonic organ morphogenesis", "embryonic skeletal system development", "connective tissue development" (Supplementary Data 4). In addition, CX43 (encoded by GLA1) is a marker gene of CH0 fibroblasts, and CH0 fibroblasts expressed S100A4 (Supplementary Data 3, Supplementary Fig. 8e). Correspondingly, the PI3K/AKT signalling pathway was activated in CH0 fibroblasts (Supplementary Fig. 8f). Using the Kaplan–Meier plotter dataset (https://kmplot.com/analysis), we explored the prognostic value of CH0 fibroblasts in patients with cancer receiving chemotherapy. Three marker genes (ZIP1, S100A4, CX43) were used as inputs, and overall survival was evaluated. The results showed that high expression of the three marker genes was associated with poor survival in patients with lung cancer receiving chemotherapy (Supplementary Fig. 8g). Interestingly, high expression of the three marker genes was also associated with poor survival in gastric and ovarian, but not breast, cancer patients with chemotherapy, implying that ZIP1 fibroblasts might contribute to chemoresistance of additional human cancer types.

The clinical relevance of ZIP1 fibroblasts in lung cancer chemoresistance was further investigated in a cohort of 90 lung adenocarcinoma patients who underwent chemotherapy (Supplementary Data 5). First, using immunofluorescence staining, we observed that CX43 was co-localised between ZIP1 fibroblasts and cancer cells in human lung adenocarcinoma, implying gap junction formation between these two cell types (Supplementary Fig. 9a). ZIP1 expression in stromal cells was evaluated, and patients were classified into high or low ZIP1 expression groups according to histological scores. High ZIP1 expression in stromal cells (ZIP1*+) was associated with a poor prognosis (Fig. 8a, b). To evaluate the expression of ZIP1 more specifically in fibroblasts, double-staining of ZIP1 and α-smooth muscle actin (α-SMA) was performed (Fig. 8c). ZIP1 expression in fibroblasts was significantly higher in tumour tissue than in paratumour tissue (Fig. 8d).
**Fig. 7 | S100A4 increases ZIP1 expression in fibroblasts.** a, b ZIP1 expression in mCAF treated with DOX at the indicated doses (a) or for the indicated times (b). Representative results from three (a, b) independent experiments are shown.

**c** S100A4 levels in the same volume of LLC-GFP-luc cell culture mediums (CMs) with or without DOX treatment determined by western blotting. The same number of tumour cells were seeded and pre-treated with DOX (1 μM) for 6 h. Twenty-four hours after changing the fresh medium, CMs were collected. The same volume of CM from different treatment groups was analysed by Western blotting. A representative result from three independent experiments is shown.

d ZIP1 expression in mCAF treated with indicated CM. For S100A4 neutralisation, CM was pre-incubated with α-S100A4 antibody 3B11 (6 μg/mL) for 1 h. A representative result from four independent experiments is shown.

**e** ZIP1 expression in mCAF treated with S100A4 at the indicated times (e) or for the indicated times (f). β-actin was used as control. The samples derived from the same experiment and blots were processed in parallel. Representative results from three (e, f) independent experiments are shown.

**g, h** Expression of phosphorylated p65 (pp65), p65, phosphorylated ERK (pERK) (g), phosphorylated AKT (pAKT), AKT, phosphorylated p38 (pp38), and p38 (p) in mCAF treated with S100A4 for the indicated time periods. β-actin was used as control. The samples derived from the same experiment and blots were processed in parallel. Representative results from three (g, h) independent experiments are shown.

**i** Expression of ZIP1 in mCAF treated with S100A4, SB202190 (p38 inhibitor, 50 μM), U0126 (ERK inhibitor, 10 μM), SC75741 (p65 inhibitor, 8 μM), and LY294002 (AKT inhibitor, 25 μM) as indicated. A representative result from three independent experiments is shown.

**j** Expression of ZIP1 in mCAF treated with S100A4, TLR4-IN-C34 (TLR4 inhibitor, 10 μM), and FPS-ZM1 (RAGE inhibitor, 1 μM), as indicated. A representative result from three independent experiments is shown.

**k** Diagram showing the signalling pathways for the regulation of ZIP1 by S100A4.

**l** Extracellular S100A4 in LLC-GFP-luc tumours, with or without DOX treatment. n = 6 for the PBS group and n = 7 for the DOX group. Data are presented as mean ± SEM, n = 6 for PBS, n = 7 for DOX. Two-tailed t-test. Source data are provided as a Source Data file (a–j, l).
The percentage of α-SMA+ZIP1+ fibroblasts was also higher in tumour tissues than in paratumour tissues. In most tumours, the proportion of ZIP1+ fibroblasts was >50% (Fig. 8d). Moreover, ZIP1high fibroblast status predicted poor overall and progression-free survival (Fig. 8e, f), indicating an association between ZIP1high fibroblasts and chemoresistance in lung adenocarcinoma. Although significant associations were observed between ZIP1 status and mortality and sex, there was no association with pathological grading or clinical stage (Supplementary Fig. 9b). In patients with no observed relapse and those with pathological grade 2, ZIP1high fibroblast status was an especially powerful predictor of poor survival (Fig. 8g, h). Furthermore, we performed analysis on patients who received paclitaxel or docetaxel (together as a taxane) in combination with cisplatin.
“Taxane”) (Supplementary Data 5). In these patients, ZIP1low status was associated with significantly better overall and progression-free survival than ZIP1high status (Fig. 8i, j), indicating that ZIP1high status is associated with resistance to taxane-containing regimens. Moreover, in another cohort of 30 lung adenocarcinoma patients (Supplementary Table 4), we found that ABCB1 expression in tumour cells was positively correlated with ZIP1 expression in CAFs (Fig. 8k). These results suggested that ZIP1low fibroblasts are associated with poor survival and may contribute to chemoresistance in lung cancer. Collectively, our findings revealed that ZIP1 fibroblasts interconnect lung cancer cells by upregulating CX43 and promoting chemoresistance via Zn2+ transfer (Fig. 9).

**Discussion**

Short-range fibroblast–tumour interactions, including physical contact during chemotherapy, have scarcely been reported. Early studies reported that fibroblasts coupled with tumour cells through gap junctions transmit bystander cytotoxicity39. In contrast, gap junctions between cancer cells and stromal cells may also support tumour growth and chemoresistance40. The regulation of fibroblast–tumour gap junction intercellular communication in lung cancer and its effect on chemotherapy are unknown. In this study, we found that ZIP1 fibroblasts were enriched in tumours treated with DOX. Unexpectedly, ZIP1 fibroblasts formed efficient gap junctions with lung cancer cells by upregulating CX43 expression. This coupling enables the transfer of Zn2+ from fibroblasts to cancer cells, inducing ABCB1-mediated drug extrusion and chemoresistance. These findings are clinically relevant, as demonstrated by the association of ZIP1high fibroblast status with poor survival and chemoresistance in patients with lung cancer. Our results provide insights into short-range fibroblast–tumour interactions and have important implications for the design of strategies to overcome chemoresistance in lung cancer.

ZIP1 fibroblast enrichment results from adaptation to chemotherapy-induced tissue damage. Chemotherapy kills tumour cells and remodels the tumour stroma. The cellular contents released from dying cells, such as cell debris, HMGB1, ATP, and annexin A1, can be engulfed or sensed by phagocytes as danger-associated molecular patterns (DAMPs) to stimulate long-term adaptive antitumour immunity42. In contrast, some cellular contents released from dying cells, such as K+, can generate an immunosuppressive niche by inhibiting T-cell activation41. Therefore, cell death may trigger antitumour or protumour responses for unknown reasons. This may reflect diverse cell death types, such as apoptosis or pyroptosis, which usually stimulate rare or strong inflammation43. Alternatively, different sensors, such as macrophages or fibroblasts, for released cell contents may exert distinct effects on tumour progression. In this study, we demonstrated that ZIP1 fibroblasts are enriched after chemotherapy. ZIP1 fibroblasts probably act as sensors of Zn2+ released from dying cells and recycle it for usage, causing tumour drug resistance. Our results suggested that chemotherapeutic drugs do not directly upregulate ZIP1 expression in fibroblasts. Instead, S100A4, which can be induced by chemotherapy, increased the expression of ZIP1 in fibroblasts. In the livers and lungs, we have demonstrated that tissue injury induces an increase in extracellular S100A44,45,62. NF-κB, AKT, and p38

**Fig. 8 | ZIP1high fibroblasts are associated with poor survival and chemoresistance in patients with lung cancer.** a Representative ZIP1 staining in lung adenocarcinoma (LA) tissues. A human liver section was used as a positive control. Arrow, ZIP1+ fibroblasts. Representative staining results from 68 lung cancer samples are shown. b Survival curve of patients with lung adenocarcinoma with stroma ZIP1high or stroma ZIP1low status. c Double-staining of ZIP1 and α-SMA in lung cancer tissues including tumour and paratumour tissue. Representative staining results from 90 tumour and 90 corresponding paratumour samples are shown. d ZIP1 expression levels in fibroblasts and percentage of ZIP1+ fibroblasts in tumour and paratumour tissues (n = 90). Data are presented as median with interquartile range.

![Fig. 9 | ZIP1+ fibroblasts interconnect lung cancer cells via upregulating CX43 and promote chemoresistance by Zn2+ transfer.](image)

**Fig. 9 | ZIP1+ fibroblasts interconnect lung cancer cells via upregulating CX43 and promote chemoresistance by Zn2+ transfer.** Chemotherapy treatment induces Zn2+ released from dying cancer cells and the enrichment of ZIP1+ fibroblasts. ZIP1+ fibroblasts interconnect cancer cells with gap junctions by upregulating CX43. Upon treatment, the ability of Zn2+ uptake by cancer cells is suppressed.
are involved in the S100A4-mediated upregulation of ZIP1. Therefore, we conjecture that chemotherapy-related tissue damage causes an increase in S100A4, which enhances ZIP1 expression in fibroblasts and is possibly responsible for recycling Zn\(^{2+}\) in the dying niche.

ZIP1\(^{-}\) fibroblasts uniquely coordinate with tumour cells through gap junctions. Multicellular organisms have evolved diverse strategies to communicate between cells for cellular coordination, including long-range interactions mediated by neural or endocrine, or short-range interactions mediated by direct cell–cell contact\(^{25}\). From an organic perspective, tumour and stromal cells adopt similar communication strategies. Although long-range fibroblast–tumour interactions by secretion have been extensively studied, short-range fibroblast–tumour interactions have scarcely been reported\(^{26}\). Fibroblasts secrete IL-6 and IL-8 to maintain cancer stem cells\(^{4}\). Fibroblasts release glutathione and cysteine to reduce cisplatin accumulation in ovarian cancer\(^{41}\). Tumour-derived miRNA-containing exosomes may activate fibroblasts, which in turn can promote lung metastasis\(^{22,46}\).

Fibroblasts can also modulate tumour vascular function by secreting VEGF\(^{8,47}\). For short-range interactions, we and others have reported that fibroblasts engage in physical contact, leading to the invasion of cancer cells\(^{11,12}\). In this study, we demonstrated that ZIP1\(^{-}\) fibroblasts specifically upregulate CX43 and form gap junctions with cancer cells. These results suggest that gap junctions possibly enable the direct transfer of Zn\(^{2+}\) to tumour cells. Logically, gap junctions may also allow the transmission of other substrates, such as ATP and cGAMP, which requires further study. In support of our results, Maynard et al. reported that cancer cells surviving on therapeutic progress are deprived of gap junction pathway in lung cancer patients with targeted therapy\(^{45}\). ZIP transporters have been reported to transport zinc as well as other metals, such as iron (Fe) and manganese (Mn)\(^{49}\).

Another interesting question is whether ZIP1\(^{-}\) fibroblasts can transport other metals and affect metal levels in cancer cells. Additionally, ZIP1\(^{-}\) fibroblasts might also have the potential to interact with other stromal cells, such as endothelial and immune cells, to affect tumour progression.

Thus, ZIP1\(^{-}\) fibroblasts may represent a specific fibroblast phenotype. The diverse functions of CAFs may reflect different subtypes of CAFs in tumours\(^{2}\). An inflammatory CAF (iCAF) phenotype has been identified in different cancer types which recruit macrophages to establish an immunosuppressive microenvironment\(^{1}\). In lung cancer, scRNA-seq has previously identified five clusters of fibroblasts, including two ECM phenotypes (ecmCAFs), one myCAF, and two metabolic phenotypes\(^{8}\). In this study, fibroblast Cluster 6 was consistent with myCAFs and Cluster 7 resembled ecmCAFs. ZIP1\(^{-}\) fibroblasts are enriched after chemotherapy and have enhanced abilities to form gap junctions and absorb and transfer Zn\(^{2+}\) to lung cancer cells, leading to chemoresistance. Therefore, we argue that ZIP1\(^{-}\) fibroblasts represent a CAF subtype with a developmental phenotype and zinc transport activity. In both mouse and human lung cancers, these fibroblasts are ZIP1\(^{-}\)S100A4\(^{10}\)CX43\(^{8,45}\)CAF. We propose that ZIP1\(^{-}\)S100A4\(^{10}\) CX43\(^{8,45}\)CAF may be called zinc-transport CAF (zCAF), which absorbs and transfers Zn\(^{2+}\) to neighbouring cancer cells through gap junctions. The PDK\(^{2}\)/AKT signalling pathway probably drives the generation of zCAF. Except for zCAF, our results indicate that ZIP1 might also be expressed in fibroblasts with low gap junction protein expression, which may reflect low levels of Zn\(^{2+}\) in these cells, and these cells might have the potential to become zCAF when encountering adequate Zn\(^{2+}\). To further define the specific function of zCAF, it will be useful to develop strategies for the isolation of zCAFs in future studies.

Zn\(^{2+}\) uptake by ZIP1\(^{-}\) fibroblasts contributes to tumour chemoresistance. Zinc is an essential trace element for cell proliferation and survival\(^{11}\). Besides structural Zn\(^{2+}\), there is a small amount of loosely bound Zn\(^{2+}\), known as free or labile Zn\(^{2+}\), representing a physiological source of accessible Zn\(^{2+}\)\(^{2,21}\). Reduced cytoplasmic Zn\(^{2+}\) related to ZIP1 deficiency leads to B cell development failure\(^{12}\). ZIP14-mediated Zn\(^{2+}\) uptake in muscle progenitor cells represses the expression of Mdyo and Mef2c and blocks muscle cell differentiation, driving cancer-induced cachexia\(^{46}\). Zn\(^{2+}\) import by ZIP4 has been linked to cancer cell proliferation, resistance to apoptosis, cachexia in pancreatic cancer\(^{41}\), and metastasis in lung cancer\(^{2}\). It has been reported that serum Zn\(^{2+}\) levels are low in many cancers, including lung cancer\(^{13,45}\). However, Zn\(^{2+}\) dynamics are unclear, especially in tumour chemotherapy. We found that chemotherapy-induced cancer cell necrosis, releasing labile Zn\(^{2+}\) into the extracellular space. Upon treatment, cancer cells were suppressed to take up Zn\(^{2+}\) from the extracellular space, possibly resulting in zinc-deficient conditions for cancer cells. ZIP1\(^{-}\) fibroblasts can act as Zn\(^{2+}\) reservoirs to absorb Zn\(^{2+}\) and transfer it to cancer cells through gap junctions, thereby leading to ABCB1-mediated drug extrusion in lung cancer cells. Brain endothelial cells use a similar mechanism to prevent drug toxicity\(^{41}\). Our findings demonstrate that ZIP1-mediated upregulation of CX43 is fibroblast-origin independent, implying that this mechanism might apply to both primary tumours and distant metastases of lung cancer treated with chemotherapy. In fibroblasts, Zn\(^{2+}\) stimulated PTEN degradation, consistent with previous findings\(^{48}\). Inhibition of PTEN by Zn\(^{2+}\) has been linked to AKT activation and CX43 upregulation, paving the way for Zn\(^{2+}\) transfer. A study has reported that Zn\(^{2+}\) reduced CX43 expression in astrocytes\(^{50}\), possibly because of the different cell types. In fibroblasts with zinc transport deficiencies, vimentin-filament stability is impaired\(^{40}\). Thus, Zn\(^{2+}\) in fibroblasts and cancer cells may also regulate other signalling pathways that require further exploration.

ZIP1\(^{-}\) fibroblasts are clinically relevant in patients with lung cancer. We found that expression of ZIP1 in the tumour stroma, specifically in fibroblasts, was associated with chemotherapy resistance in lung adenocarcinoma, and correlated with ABCB1 expression in the tumour cells of lung cancer patients. Specifically, ZIP1\(^{\text{high}}\) fibroblast status was associated with resistance to taxane-containing drug regimens. Therefore, clinical testing of fibroblast ZIP1 expression in lung cancer could inform the choice of therapeutic drug regimens. Considering that a series of therapeutic drugs are substrates of ABCB1, the association between ZIP1\(^{\text{high}}\) fibroblasts and multiple chemotherapies merits further study. Finally, our results imply that ZIP1\(^{-}\) fibroblasts may also contribute to chemoresistance in other cancer types, such as gastric cancer, which requires further study. Taken together, our results reveal a specific fibroblast–lung cancer cell short-range interaction via CX43-mediated gap junctions, which contributes to chemoresistance via Zn\(^{2+}\) transfer.

Methods

Animals

The Ethics Committee of Scientific Research and Clinical Trial at the First Affiliated Hospital of Zhengzhou University approved this study (2020-KY-349, 2021-KY-026-002). C57BL/6-Egfp mice were originally from Osaka University (Osaka, Japan)\(^{19}\). Female C57BL/6, nude, and NOD-SCID mice were purchased from Vital River Laboratories (VRL, Beijing, China). ZIP1-deficient mice (Sck39a1t) on a C57BL/6 background were purchased from Cyagen (KOCMP-30791-Sck39a1-B6; Suzhou, China). Exon 3 of the Sck39a1/Skip gene was deleted by CRISP/Cas-mediated genome engineering. Zip1\(^{+}\), Zip1\(^{-}\) and Zip1\(^{+/}\) mice were identified using two pairs of PCR primers (Primer pair 1: F1: 5'-TCTCTGTATAGTGCTCAAGAGTCAC-3'; R1: 5'-TGAAGGGGAGGAGAAACAAATA. Primer pair 2: F2: 5'-CATGTGACGCTAGACATGCTT-3'; R2: 5'-TGAAGGGGAGGAGAAACAAATAAAGTG-3'). Female mice aged 6–8 weeks were used. All mice were housed at 21°C and 50% humidity, on a average, on a 12 h light/dark cycle in a specific pathogen-free facility at Zhengzhou University.

Cell culture

The mouse lung cancer cell line LLC and the human lung cancer cell lines A549 and H299 (ATCC, LGC Standards) were cultured in...
**Cell culture and cDNA synthesis**

Using the Chromium Single Cell 3’ GEM Library & Gel Bead Kit v3 (10x Genomics, Shanghai, China, 1000075) and Chromium Single Cell B Chip Kit (10x Genomics, 1000074), the cell suspension (1000 living cells per microlitre determined by Count Star) was loaded onto the Chromium single-cell controller (10x Genomics) to generate single-cell gel beads in the emulsion, according to the manufacturer’s protocol. Briefly, single cells were suspended in PBS containing 0.04% BSA. -12,000 cells were added to each channel and target cell recovery was estimated to be ~6000 cells. Captured cells were lysed and the released RNAs were barcoded through reverse transcription in individual GEMs. Reverse transcription was performed on an SI1000TM Touch Thermal Cycler (Bio-Rad) at 53 °C for 45 min, followed by 85 °C for 5 min, and held at 4 °C. The cDNA was generated and amplified, and the quality was assessed using an Agilent 4200 (CapitalBio Technology, Beijing, China).

**scRNAseq library preparation**

According to the manufacturer’s instructions, scRNA-seq libraries were constructed using Chromium Single Cell 3’ GEM Library & Gel Bead Kit v3. The libraries were sequenced using an Illumina Novaseq6000 sequencer with a sequencing depth of at least 100,000 reads per cell using a paired-end 150 bp (PE150) reading strategy (performed by CapitalBio Technology). The raw sequence data of mouse EGFP CD45 stromal cell scRNA-seq reported in this paper have been deposited in the Genome Sequence Archive\(^{16}\) of the National Genomics Data Center\(^{17}\), China National Center for Bioinformation/Beijing Institute of Genomics, Chinese Academy of Sciences, under accession number CRA004556. Single-cell sequencing datasets of human lung adenocarcinoma were downloaded from NCBI’s Gene Expression Omnibus (GSE123904), which has been previously published\(^{18}\).

**Alignment and quantification**

Cell Ranger v2.1.0 with default settings was used to perform read alignment, barcode processing, and single-cell gene counting. Briefly, the FASTQ files for each library were processed individually using the Cell Ranger Count pipeline, which made use of STAR v2.5.2b (Alexander Dobin) to align cDNA reads to the mm10 mouse reference genome. The cell barcodes and UMI associated with the aligned reads were filtered and corrected. The retained reads were used to collapse the PCR duplicates and accurately quantify the number of transcript molecules captured for each gene in each cell.

**Quality control and batch-effect correction**

Seurat v2.1.0 (R version 3.6.0, the R project) was used to control cell and gene quality. Cells containing fewer than 1000 expressed genes were removed. Genes that were expressed in fewer than 10 cells were also removed. For each cell, the counts were normalised to the total counts and then multiplied by a scale factor of 100,000 before transforming to the log2 scale. To identify highly variable genes, the relationship between mean expression and dispersion was fitted using LogVMR as a dispersion function. FindIntegrationAnchors and IntegrateData functions with default parameters were used to correct the
batch effect and merge the datasets. The count matrix is then scaled, centred, and used for dimensionality reduction and clustering.

### Dimensionality reduction, clustering and marker selection

To reduce the dimensionality of the dataset, the variously expressed genes were summarised using principal component analysis, and the first 20 principal components were summarised using UMAP dimensionality reduction using the default settings of the RunUMAP function. The scores of cells along these principal components were used to build a k-nearest-neighbour graph and partition the cells into transcriptionally distinct clusters using the smart local moving community detection algorithm, as implemented in the FindClusters function in Seurat. To identify marker genes for each cluster, we contrasted cells from that cluster with all other cells of that cluster using the Seurat FindMarkers function. Marker genes were required to have an AUC value > 0.7 using ROC analysis to classify cells between clusters. Additionally, marker genes were required to have the highest mean expression in that cluster out of all clusters.

### Gene-set variation analysis (GSVA)

Pathway analyses were predominantly performed on the 50 hallmark pathways described in the molecular signature database and exported using the msigdb package v7.4.1. GSVA was applied using standard settings as implemented in the GSVA package v1.40.1. The pathway activity scores of the cells were used to calculate t-values using the moderated t-test in Limma v.3.36.2. The t-values were plotted as a heatmap using ggplot2 v.2.2.1.

### RNA velocity

For RNA velocity analysis, the spliced and unspliced matrices of reads were summarised using velocyto v.0.17.1763 with default parameters from aligned bam files generated by Cell Ranger. The resulting loom object for each sample was loaded and processed using velocyto.R from the aligned bam files.

### Gene expression programmes (GEPs) analysis

The cNMF algorithm v1.4 (Dylan Kotliar) was applied to the cells of clusters 0–3 to identify activation programmes (GEPs). In brief, non-negative matrix factorisation was run 100 times for T=0.1 was selected to complete the consensus step for cNMF.

### Pathway activity estimation

To compare pathway activity among seven clusters, we used PROGENy v1.14.0 to estimate the activity of 14 pathways using the top 500 most responsive genes from the model as it is recommended from a benchmark study.

### RNA extraction and qPCR

For RNA extraction and qPCR, total RNA was extracted from the samples using TRIzol reagent (9109, Takara, Shiga, Japan) according to the manufacturer’s instructions. First-strand cDNA was synthesised from 1µg of total RNA using a Prime Script RT reagent kit (RR047A, Takara). qPCR was performed using SYBR Premix Ex Taq II (RR820A; Takara). qPCR was performed using SYBR Premix Ex Taq II (RR820A; Takara). qPCR was performed using SYBR Premix Ex Taq II (RR820A; Takara) and assessed using an Agilent Mx3000P instrument. The abundance of mRNA for each gene of interest was normalised to that of 18S rRNA. The following primers were used: mZip1 Fw, GGATCTCAGGAGCCTGAGAT; mZip1 Rw, GCCAGACGCTCAAGACAT; hZip1 Fw, TGAAGTCATAGCTGCTAGGGCC; hZip1 Rw, CACGGGCACCATCCTGGCA; 18S, ACCGCACGAGAATAGAATC; AAATCCTTCGCTCGTC.

### Transfection

For transfection, fibroblasts were seeded at a density of 2 × 10⁴ cells/well in six-well plates. The following day, DNA constructs or siRNA targeting Zip1 and the control were mixed with lipofectamine-3000 (Lipo, Invitrogen, Shanghai, China) in Opti-MEM (1:1, v/v), and the mixture was incubated for 15 min at room temperature. The DNA–lipo complexes were then added to the cells. For knockdown, experiments were performed 2 days after transfection. For overexpression, the transfected cells were screened for 7–10 days by the addition of corresponding antibiotics. After selection, the antibiotics were removed and the cells were used for experiments. pcDNA3.1-mZip1 carrying mouse Zip1 cDNA under the control of the CMV promoter, was constructed by Sangon Biotech (Shanghai, China). pCMV-hZIP1 carrying human ZIP1 cDNA under the control of the CMV promoter was purchased from Sino Biological (HGI6650-NM; Beijing, China). Tetra-cycline (Tet)-off system-controlled Zif64 expression was constructed as previously described. The mCAFs were first transfected with pTet-off (BD Biosciences, San Jose, CA, USA). After selection, cells were transfected with pTRE2-mZip1 carrying mouse Zip1 cDNA under the control of a mutant CMV promoter (TET-Zip1) or empty pTRE2 (TET-mock).

### Western-blotting analysis

Cells were lysed with RIPA lysis buffer and the lysates were collected. Proteins were separated by 10% SDS-PAGE and transferred onto polyvinylidene difluoride (PVDF) membranes. The membrane was incubated with the primary antibody, and the specific binding of the primary antibody was detected with HRP-conjugated goat anti-rabbit (1:2000, 31460) or goat anti-mouse (1:2000, 31430) secondary antibody (Invitrogen). The following primary antibodies were used: ZIP1 (1:1000, A03-ALZ-Z001; Alomone, Israel), AKT (1:1000, clone 40D4, 2920; CST, USA), pAKT (1:1000, clone D25E6, 13038; CST, USA), PTEN (1:1000, clone D4.3, 5832; CST, USA), pp38 (1:1000, clone D3F9, 4311; CST, USA), p38 (1:1000, clone D13E1, 6990; CST, USA), pERK (1:1000, clone D13.14.4E, 4370; CST, USA), ABCB1 (1:1000, clone C219, MA1-26528; Invitrogen, USA), GFP (1:1000, clone GF28R, MA5-15256, Invitrogen). RFP (1:1000, clone RSRF, MA5-15257 Invitrogen), CX43 (1:1000, 26980-1-AP; Proteintech Group, China), S100A4 (1:1000, clone 3B11, kept in our Lab) and β-actin (1:6000, clone 2D4H5, 66009-1-Ig; Proteintech, Wuhan, China).

### DNA damage and DOX content

5 × 10⁴ LLC-GFP-luc cells were seeded into individual wells of 12-well plates and cultured overnight. The next day, 1 × 10⁴ Zip1- or Zip1+ MEFs were added to the culture in DMEM + 10% FBS + 5 µM TPEN. DOX (3 µM) was then added. After 4 h, to detect DNA damage, cells were collected and stained with GFP (1:100, clone B-2, AG281, Beyotime, Shanghai, China) and γ-H2AX (1:200, clone 20E3, 9718, CST, USA). Donkey anti-mouse (1:200, A-21202) and anti-rabbit (1:200, A-21573, Invitrogen, Shanghai, China) secondary antibodies were used to detect GFP and γ-H2AX, respectively. The expression of γ-H2AX in individual tumour cells was analysed using FACS or confocal microscopy. To detect DOX content in individual tumour cells, the cells were collected, and DOX fluorescence was directly determined by FACS at FL3 or confocal microscopy. To detect ABCB1 or CX43 expression, the cells were stained with appropriate antibodies. After washing, the cells were stained with donkey anti-rabbit AF647 antibody (1:200, A-31573) and analysed using FACS. To quantify the mean fluorescence intensity (MFI) or relative MFI was calculated. Relative MFI was calculated as the MFI of the sample/MFI of the negative control.

### Flow cytometry

Rabbit anti-ABC1 (1:100, 22336-1-AP, Proteintech) and rabbit anti-CX43 (1:100, 26980-1-AP, Proteintech) were used as primary antibodies to stain the cell suspensions, and Alexa Fluor 647 donkey anti-rabbit IgG (H + L) (1:200, A-31573, Thermo Fisher Scientific) was used as the secondary antibody. PE/Cy7 anti-mouse CD31 (1:100, 102418, 31460) was added to the cell suspension, and Alexa Fluor 647 donkey anti-rabbit IgG (H + L) (1:200, A-31573, Thermo Fisher Scientific) was used as the secondary antibody. PE/Cy7 anti-mouse CD31 (1:100, 102418, 31460) was added to the cell suspension, and Alexa Fluor 647 donkey anti-rabbit IgG (H + L) (1:200, A-31573, Thermo Fisher Scientific) was used as the secondary antibody.
BioLegend) and Alexa Fluor 700 anti-mouse CD45 antibodies (1:100, 147716, BioLegend) were used to stain the endothelial and immune cells. Dead cells in samples were excluded by propidium iodide (PI) staining in indicated experiments. Samples were analysed using Canto II with BD FACSDiva software v8.0.1, and the results were analysed using FlowJo v10 (BD Bioscience, USA). Gating strategies have been provided in the figures as well as in Supplementary Fig. 10.

**Histopathology and immunostaining**

The Ethics Committee of Scientific Research and Clinical Trial at the First Affiliated Hospital of Zhengzhou University approved this study (2020-KY-349, 2021-KY-0626-002). Tumour tissues were harvested and embedded in the O.C.T. compound, frozen, and cut using a cryostat. For histological staining of tumour tissues, frozen sections (7 μm thick) were stained with rat anti-ER-TR7 (1:100, clone ER-TR7, ab51824, Abcam, Cambridge, UK), goat anti-α-SMA (1:100, ab21027, Abcam), and rabbit anti-ZIP1 (1:100, ALG-001, Alomone, Israel) antibodies. A human lung adenocarcinoma tissue microarray (TMA) with survival data was purchased from Zuocheng Bio (TLungAd-01, Shanghai, China). The TMA represented 90 lung adenocarcinoma cases that were treated with chemotherapy. Another TMA, representing 30 lung adenocarcinoma cases, was purchased from Outdo Biotech (HILungA06-C002, Shanghai, China). For immunohistochemistry, tissue sections were deparaffinised and incubated in citrate buffer at 95 °C for 40 min for antigen retrieval, and then incubated overnight at 4 °C with primary antibodies anti-ZIP1 (1:100 dilution) and anti-α-SMA (1:100 dilution). After three washes, the tissue sections were incubated with AP-conjugated anti-rabbit antibody and HRP-conjugated anti-goat antibody (1:200 dilution) for 1 h at room temperature. After three washes with PBS, Fast Red or DAB solution was added and the slides were counterstained with haematoxylin. Negative controls were treated in the same manner, except without the addition of primary antibodies. Co-staining of ZIP1, α-SMA, and ABCB1 in TMA s was performed according to the manufacturer’s instructions using a PANO multiplex IHC 6-colour kit (PNI00718A, PANOVUE, Beijing, China). ZIP1 was labelled with PP620, α-SMA with PP520, and ABCB1 with 540. The results of immunohistochemical staining were acquired and assessed a Vectra 3.0 (Perkin Elmer). The tumour and stroma areas were auto-recognised by training the machine according to staining with Inform software 2.1.1. The percentage of immunoreactive cells and staining intensity were evaluated using the Inform software. The staining extent score was on a scale of 0–300, corresponding to the percentage of immunoreactive stromal cells (0–10%, 11–25%, 26–75%, and 76–100%) and staining intensity (negative, score = 0; weak, score = 1; strong, score = 2; extraordinarily strong, score = 3). A score ranging from 0 to 300 was calculated using the staining extent score × intensity score × 100. The cutoff of the histological score for ZIP1 single-staining was 150 (low, 0–150; high, 150–300) and for ZIP1/α-SMA double-staining was 230 (low, 0–230; high, 230–300). The expression level of ZIP1 in each specimen was defined as low or high.

**Inhibition rate and cell viability**

Fibroblasts or tumour cells (5 × 10^5) were seeded into individual wells of 96-well plates. The next day, DOX and the drugs were added to treat the cells for 24 h, and the remaining live cells were detected by propidium iodide (PI) staining, and the percentage of live cells was calculated as OD450(control)−OD450(sample)/OD450(control)×100%.

To evaluate the protective effect of fibroblasts on tumour cell viability, MEFs were co-cultured with LLC-GFP-luc cells and treated with DOX. Briefly, LLC-GFP-luc cells (5 × 10^5) were seeded into 96-well plates and cultured overnight. The following day, MEFs (1 × 10^5) were added to the cultures. DOX (3 μM) was added to the cells. Alternatively, MEFs (1 × 10^5) were seeded into the plate first, and the next day LLC-GFP-luc cells (1 × 10^5) were added. DOX (1 μM) was added as a treatment. After 24 h, 1.5 mg/ml α-luciferin (4001E030, YEASON, Shanghai, China) was added to the culture to detect luciferase activity in LLC-GFP-luc cells. Untreated LLC-GFP-luc cells were used as controls. Tumour cell viability was evaluated by the activity of luciferase in LLC-GFP-luc cells as luminescence [sample]/luminescence [control]×100%.

**Intracellular Zn²⁺ determination by FACS**

To detect intracellular Zn²⁺ using FACS, 5 × 10^5 LLC cells were seeded into individual wells of 12-well plates and cultured overnight. The following day, LLC cells were loaded with 2 μM FluoZin3-AM (F24195, Invitrogen) for 1 h at room temperature and treated with different concentrations of ZnCl₂ in DMEM + 10% FBS + 5 μM TPEN (P4413, Sigma-Aldrich) for 20 min. After treatment, the cells were collected and FluoZin3 fluorescence was analysed using Canto II (Becton Dickinson). LLC cells treated with FluoZin3 were treated with 5 μM TPEN in FACS buffer and used as a negative control. For the co-culture of A549 and hCAFs, A549 cells were pre-stained with 3 μM CM-Dil (4071E6S60, Yeason) at 37 °C for 30 min in DMEM. hCAFs were then added to the culture in DMEM supplemented with 10% FBS. After 3 h of co-culture, the cells were loaded with 2 μM FluoZin3-AM at room temperature for 1 h in DMEM and analysed using FACS. Cells without FluoZin3 labelling were used as negative controls.

**Zn²⁺ transfer**

5 × 10^5 A549 cells were seeded into individual wells of 96-well black plates (165305, NUNC, Shanghai, China) and cultured overnight. After loading with 2 μM FluoZin3-AM for 1 h, the A549 cells were co-cultured with 1 × 10^5 hCAFs for 2 h in DMEM. After changing DMEM to HBSS (136.9 mM NaCl, 5.4 mM KCl, 0.4 mM KH₂PO₄, 0.3 mM Na₂HPO₄, 25 mM HEPES, 5.6 mM D-glucose) supplemented with 1.26 mM CaCl₂, the FluoZin3 fluorescence was read by SpectraMAX i3X (Molecular Devices, CA, USA) at 525 nm to evaluate the intracellular labile Zn²⁺.

Alternatively, 5 × 10^3 LLC or A549 cells were seeded into individual wells of 96-well black plates and cultured overnight. After loading with 2 μM FluoZin3-AM for 1 h, LLC or A549 cell culture was added with 1 × 10^5 MEFs or hCAFs in HBSS (+1.26 mM CaCl₂). Sixty seconds after addition, FluoZin3 fluorescence was read every 30 s for the indicated times to evaluate the changes in intracellular labile Zn²⁺ in tumour cells. All values minus the values of the blank group were used to evaluate intracellular Zn²⁺. Six-time points of tumour-cell fluorescence (F) without co-culture at the beginning were used as F₀, and the alteration in intracellular Zn²⁺ was calculated as ΔF/F₀, where $\Delta F = F - F_0$. The origin was forced to zero, and 60 s was applied to the start time of the measurement.

**Zn²⁺ uptake**

To detect Zn²⁺ uptake, 1 × 10⁵ fibroblasts or tumour cells were seeded into individual wells of 96-well black plates and cultured overnight. After loading with 2 μM FluoZin3-AM for 1 h, 30 μM ZnCl₂ was added to HBSS. Sixty seconds after addition, FluoZin3 fluorescence was read every 30 s for the indicated times to evaluate the changes in intracellular labile Zn²⁺ in cells. The TPEN treatment was used as the negative control. All values minus the values of the blank group were used to evaluate intracellular Zn²⁺. Six-time points of cell fluorescence (F) without co-culture at the beginning were used as F₀, and the alteration in intracellular Zn²⁺ was calculated as ΔF/F₀, where $\Delta F = F - F_0$. The origin was forced to zero, and 60 s was applied to the start time of the measurement.

**Zn²⁺ quantitation in tumour interstitial fluid**

LLC tumour cells (1 × 10⁶) were inoculated subcutaneously into EGFP mice. When the tumour volume reached approximately 200 mm³, 70 μg of DOX (intratumoral injection) was added. After 1 week, the
tumour interstitial fluid (TIF) was collected as previously described. Zn²⁺ concentration was determined using an AmpltiteFluorimetric Zinc Ion Quantitation Kit (AAT-19000, AAT Biocoust, CA, USA).

Calcein transfer
A549 cells (5 × 10⁴) were seeded into individual wells of 12-well plates and labelled with CM-Dil. PCCAFs or hCAFs were loaded with 0.5 µM calcein-AM and co-cultured for the indicated times in DMEM + 10% FBS. Heptanol (2 mM) was used to block the gap junctions. After treatment, calcein fluorescence in tumour cells was determined by FACS.

Determination of S100A4 by ELISA
LLC-GFP-luc tumour-bearing mice were treated with PBS or DOX as described above. Two days after the third DOX treatment, tumour tissues were collected, weighed, and cut into small pieces (2–3 mm) in cold PBS (300 µL PBS was added to 100 mg of tissue) to release extracellular protein on ice. Tumour pieces were briefly squeezed with a disposable syringe rubber plunger, and the supernatants were collected after centrifugation (300 g, 2 min, 4 °C). S100A4 in the supernatant was determined using a murine S100A4 ELISA kit (JLC2761; Shanghai Jingkang Biocompany, China).

Statistical analysis
All bars or symbols in the graphs represent the mean ± standard error of at least three independent experiments with similar results. The results were analysed using unpaired two-tailed t-tests or Mann–Whitney test for two-group comparisons, one-way ANOVA with Tukey's post hoc analysis for multigroup comparisons, and two-way ANOVA for curve comparisons. Statistical analyses were performed using GraphPad Prism v8 (GraphPad Software, La Jolla, CA, USA). Patient pathological parameter analysis was performed using SPSS Statistics 21 (IBM, NY, USA). Contingency data were analysed using χ² tests. Survival curves were analysed using the log-rank test. Correlations were evaluated using Pearson’s correlation analysis. *P < 0.05 was considered statistically significant.

Reporting summary
Further information on research design is available in the Nature Research Reporting Summary linked to this article.

Data availability
The raw sequence data reported in this paper have been deposited in the Genome Sequence Archive at the National Genomics Data Center, China National Center for Bioinformation/Beijing Institute of Genomics, Chinese Academy of Sciences, under accession number CRA004556. Single-cell sequencing datasets of human lung adenocarcinoma were downloaded from NCBI's Gene Expression Omnibus (GSE123904), which has been previously published. The data of supplementary Fig. 8g were derived from Kaplan–Meier plotter (kmplot.com/analysis) using publicly available datasets GSE14814, GSE9013 and datasets stored in caArray [https://wiki.nci.nih.gov/display/caArray2/caArray+Directory] for lung cancer, GSE62254 for gastric cancer, datasets stored in TCGA [https://gdc.cancer.gov] for ovarian cancer, and GSE1456, GSE16446, GSE16716, GSE20271, GSE22093, GSE3494, GSE37946, GSE45255, GSE69031 for breast cancer. Source data are provided in this paper. The remaining data are available within the Article, Supplementary Information or Source Data file. Source data are provided with this paper.
