Levosimendan affects oxidative and inflammatory pathways in the diaphragm of ventilated endotoxemic mice

Willem-Jan M Schellekens¹, Hieronymus WH van Hees², Marianne Linkels², PN Richard Dekhuijzen², Gert Jan Scheffer¹, Johannes G van der Hoeven³ and Leo MA Heunks³* 

Abstract

Introduction: Controlled mechanical ventilation and endotoxemia are associated with diaphragm muscle atrophy and dysfunction. Oxidative stress and activation of inflammatory pathways are involved in the pathogenesis of diaphragmatic dysfunction. Levosimendan, a cardiac inotrope, has been reported to possess anti-oxidative and anti-inflammatory properties. The aim of the present study was to investigate the effects of levosimendan on markers for diaphragm nitrosative and oxidative stress, inflammation and proteolysis in a mouse model of endotoxemia and mechanical ventilation.

Methods: Three groups were studied: (1) unventilated mice (CON, n =8), (2) mechanically ventilated endotoxemic mice (MV LPS, n =17) and (3) mechanically ventilated endotoxemic mice treated with levosimendan (MV LPS + L, n =17). Immediately after anesthesia (CON) or after 8 hours of mechanical ventilation, blood and diaphragm muscle were harvested for biochemical analysis.

Results: Mechanical ventilation and endotoxemia increased expression of inducible nitric oxide synthase (iNOS) mRNA and cytokine levels of interleukin (IL)-1β, IL-6 and keratinocyte-derived chemokine, and decreased IL-10, in the diaphragm; however, they had no effect on protein nitrosylation and 4-hydroxy-2-nonenal protein concentrations. Levosimendan decreased nitrosylated proteins by 10% (P <0.05) and 4-hydroxy-2-nonenal protein concentrations by 13% (P <0.05), but it augmented the rise of iNOS mRNA by 47% (P <0.05). Levosimendan did not affect the inflammatory response in the diaphragm induced by mechanical ventilation and endotoxemia.

Conclusions: Mechanical ventilation in combination with endotoxemia results in systemic and diaphragmatic inflammation. Levosimendan partly decreased markers of nitrosative and oxidative stress, but did not affect the inflammatory response.

Introduction

Respiratory muscle dysfunction frequently develops in critically ill patients [1-4]. Clinical entities associated with respiratory muscle dysfunction in these patients include systemic inflammation [3,5] and controlled mechanical ventilation (MV) [6]. Recent data obtained from both animal and human studies have provided insight into the biochemical pathways underlying muscle atrophy and dysfunction in these patients [1,7-9]. Nitrosative and oxidative protein modifications are increased in the diaphragm during both MV and experimental sepsis [10,11]. Moreover, protein degradation is increased in the diaphragm in mechanically ventilated animals and patients [2,12,13]. Inflammatory cytokines are well-known modulators of muscle protein turnover during endotoxemia [14,15] and are increased in the diaphragm after MV [16,17]. For example, tumor necrosis factor (TNF)-α activates the proteolytic enzymes caspase-8 and caspase-3 in the diaphragm of mice exposed to lipopolysaccharide (LPS) [5]. Accordingly, strategies that reduce oxidative stress or inflammation may limit respiratory muscle dysfunction due to endotoxemia and MV [11,17].
Levosimendan is a cardiac inotrope approved for the treatment of heart failure in many countries worldwide. We have recently shown that levosimendan also improves respiratory muscle function in healthy subjects and patients with chronic obstructive pulmonary disease (COPD) [18,19]. The mechanisms of levosimendan include calcium sensitization of the contractile proteins and vasodilation through activation of ATP-sensitive potassium channels [20]. Interestingly, previous studies have shown that levosimendan reduces inflammation as well as oxidative and nitrosative stress [21-23]. For instance, in experimental septic rodents, levosimendan decreases interleukin (IL)-1β levels [24]. In addition, levosimendan decreases LPS-induced upregulation of IL-6, nitrite production and inducible nitric oxide synthase (iNOS) protein expression in macrophages and fibroblasts [21]. However, the effects of levosimendan on inflammation and oxidative and nitrosative stress in muscle have not been investigated, despite the importance of these pathways in intensive care unit (ICU)-acquired muscle weakness.

Accordingly, the hypothesis of the present study is that levosimendan dampens both oxidative and nitrosative stress and the inflammatory response in the diaphragm induced by endotoxemia.

**Methods**

**Animals**

Experiments were performed using male C57BL/6 mice aged 19 ± 0.5 weeks and body weight 24 ± 0.3 g (Charles River Laboratories, Sulzfeld, Germany).

To test the hypothesis that levosimendan dampens both oxidative and nitrosative stress and the inflammatory response in the diaphragm induced by MV and experimental sepsis, 42 mice were divided into 3 groups: (1) unventilated controls (CON, n = 8), (2) MV and LPS (MV LPS, n = 17) and (3) MV and LPS + levosimendan (MV LPS + L), n = 17). The effects of MV on inflammatory markers in mice have been investigated previously in our laboratory [16]. Because patients admitted to the ICU with endotoxemia often require MV, we used an animal model in which endotoxemia was administered prior to MV. In both groups, LPS (10 μg) was administered by intraperitoneal injection immediately before initiation of MV.

The final choice for the dose of LPS was based on pilot experiments. In a pilot study, we found that administration of 100 μg of LPS resulted in high mortality. Nevertheless, immediately after intraperitoneal injection of a LPS bolus, one mouse in the MV LPS + L group died and was excluded from the study. At the start of MV, mice in the levosimendan group received levosimendan (Orion Pharma, Espoo, Finland) via the tail vein at a dose of 24 μg/kg body weight in 5% glucose solution. Subsequently, levosimendan (0.2 μg/kg/min intravenously) was administered during MV [20]. The experiments were approved by the regional animal ethics committee (Nijmegen, the Netherlands) and performed under the guidelines of the Dutch Council for Animal Care.

**Controlled mechanical ventilation**

Mice selected for MV were anesthetized and mechanically ventilated as described previously [16]. Briefly, mice were anesthetized with an intraperitoneal injection of a combination of ketamine, medetomidine, and atropine (KMA): 7.5 μl/g body weight of induction KMA mix (consisting of 1.26 ml of ketamine, 100 mg/ml; 0.2 ml of medetomidine, 1 mg/ml; 1 ml of atropine, 0.5 mg/ml; and 5 ml of NaCl, 0.9%). Tidal volume was 8 ml/kg body weight, respiratory rate was 170/min, positive end-expiratory pressure was 1.5 cmH₂O and inspired oxygen fraction was 0.45. A sterile catheter was inserted into the carotid artery for continuous blood pressure measurement and blood sampling at the end of the experiment (i-STAT blood chemistry analyzer; Abbott, Hoofddorp, the Netherlands). To maintain anesthesia, a 5.0 μl/g body weight bolus of KMA mix (consisting of 0.72 ml of ketamine, 100 mg/ml; 0.08 ml of medetomidine, 1 mg/ml; 0.3 ml of atropine, 0.5 mg/ml; and 18.9 ml of NaCl, 0.9%) was administered through an intraperitoneal catheter every 30 minutes. The CON mice were anesthetized and killed without being mechanically ventilated, as described previously [16].

**Tissue collection**

Immediately after anesthesia (CON group) or after 8 hours of MV (MV LPS and MV LPS + L groups), mice were exsanguinated and a combined thoracotomy and laparotomy was performed. Left and right hemidiaphragm tissues were rinsed, quickly frozen in liquid nitrogen and stored at −80°C for later biochemical analysis [16].

**Nitrotyrosine**

Protein nitrosylation was evaluated by detection of nitrotyrosine residues by performing SDS-PAGE, as described previously [25]. In short, diaphragm muscle was homogenized in ice-cold buffer (pH 7.2, 10 mM Tris-maleate, 3 mM ethylene glycol tetaacetic acid (EGTA), 275 mM sucrose, 0.1 mM dithiothreitol (DTT), 2 mg/ml leupeptin, 2 mg/ml aprotonin, 10 mg/L pepstatin A, 0.57 mM phenylmethylsulfonyl fluoride) using a Kinematica Polytron homogenizer (Kinematica, Lucerne, Switzerland), followed by three cycles of freeze-thawing and 30 minutes of centrifugation at 17,000 g at 4°C. Supernatant protein content was measured by Bradford analysis, and 20 μg of proteins in Laemmli buffer were analyzed according to standard Western blotting protocols. Blots were stained using an anti-nitrotyrosine antibody (clone 1A6; Upstate Biotechnology, Lake Placid, NY, USA) and
goat anti-mouse IRDye 800CW (LI-COR Biosciences, Lincoln, NE, USA). Analysis was done using an Odyssey scanner and Odyssey 2.1 software (LI-COR Biosciences).

**Inducible nitric oxide synthase expression**

mRNA levels of iNOS were determined by quantitative PCR (Mm01309902_m1 mouse assay; Applied Biosystems, Foster City, CA, USA) as described previously [26].

**4-Hydroxy-2-nonenal protein**

4-Hydroxy-2-nonenal (HNE) protein was analyzed as follows. Tissue samples were homogenized in 100 volumes of buffer (20 mM Tris, pH 7.4, 20 mM EGTA, 1 mM DTT, 0.5% SDS, 1 µl/20 mg protease inhibitor cocktail (P8340; Sigma-Aldrich Chemie, Zwijndrecht, The Netherlands)) in the Kinematica Polytron homogenizer. Samples were diluted in standard Laemmli sample buffer and boiled for 2 minutes. Ten microliters of each sample were analyzed according to standard Western blotting protocols. The following antibodies were used: anti-HNE (fluorophore rabbit polyclonal antibody, catalog number 393206; Calbiochem, Darmstadt, Germany), anti-actin (A2066; Sigma-Aldrich, St Louis, MO, USA) and IRDye 800CW goat anti-rabbit immunoglobulin G secondary antibody (926-32211; LI-COR Biosciences). An Odyssey scanner and Odyssey application software version 2.1 (LI-COR Biosciences) were used for analysis of HNE protein signaling.

**Cytokines in diaphragm and plasma**

Levels of IL-1β, IL-10, TNF-α, IL-6 and keratinocyte-derived chemokine (KC) in the diaphragm and IL-1β, IL-10, TNF-α, IL-6 and KC in plasma were analyzed by enzyme-linked immunosorbent assay as described previously [27]. To determine cytokine levels in the diaphragm, the muscle was homogenized in 100 volumes of ice-cold buffer, pH 7.2 (10 mM Tris-maleate, 3 mM EGTA, 275 mM sucrose, 0.1 mM DTT, 2 mg/ml leupeptin, 2 mg/ml aprotinin, 10 mg/L pepstatin A, 0.57 mM phenylmethylsulfonyl fluoride), subjected to three cycles of freezing and thawing and centrifuged at 17,000 × g at 4°C for 30 minutes [16]. Lower detection limits were 40 pg/ml for IL-10 and IL-1β; 32 pg/ml for TNF-α; and 160 pg/ml for IL-6 and KC.

**Caspase-3 activity**

To assess involvement of proteolysis, we measured caspase-3 activity as described previously [26]. By using spectrophotometry, we determined the caspase-3 activity by measuring the generation of the fluorogenic cleavage product methylcoumarylamide from the fluorogenic substrate N-acetyl-Asp-Glu-Val-Asp-7-amido-4-methylcoumarin.

**MuRF1 and MAFbx expression**

mRNA levels of muscle RING finger (MuRF1) and muscle atrophy factor box (MAFbx) were determined by quantitative PCR [26]. Levels of MuRF1 and MAFbx mRNA were normalized to glyceraldehyde 3-phosphate dehydrogenase (GAPDH) mRNA. The forward and reverse oligonucleotides used were, respectively, as follows: MuRF1: 5′-CAAACCTGTGCGCAAGTG-3′ and 5′-CAACCTCGTGCTCAAGAGATG-3′; MAFbx: 5′-GACTGGACTTCTC GACTGCCC-3′ and 5′-TCAGCCCTGTCAATGTTTC-3′; and GAPDH: 5′-TGATGGGTGTGAACCACGAG-3′ and 5′-GGGCATCCACAGTCCTTCTCG-3′.

**Statistical analysis**

A log-rank test was performed to test differences in survival between the MV LPS and MV LPS + L groups. Differences between groups regarding the time course of mean arterial pressure were evaluated with two-way analysis of variance (ANOVA). The D’Agostino-Pearson test was used to verify normal distribution of all parameters studied. An unpaired Student’s t-test was performed to evaluate the statistical significance of differences of the following normally distributed parameters (nitrosylated proteins and HNE protein between MV LPS and MV LPS + L animals). Differences in normally distributed parameters of diaphragm KC, plasma IL-10, IL-6, KC and caspase-3 activity were analyzed with one-way ANOVA. The Student-Newman-Keuls post hoc test was used to test the probability level of differences between nominal divided groups. Differences between parameters not normally distributed (iNOS mRNA; diaphragm IL-1β, IL-10, TNF-α, IL-6, plasma IL-1β and TNF-α; MuRF1 and MAFbx mRNA) were analyzed with one-way ANOVA and Kruskal-Wallis and Dunn’s post hoc tests. For statistical analysis of cytokine measurements, the value of the detection limit was used for samples that did not reach the detection limit. GraphPad Prism software was used to conduct statistical analysis (GraphPad Software, La Jolla, CA, USA). A probability level of <0.05 was considered significant. All data are presented as mean ± SD.

**Results**

**Animal characteristics**

Blood pressure decreased progressively in both groups during 8 hours of MV (Figure 1) (P = 0.09), despite volume therapy (0.3 ml/hr). Blood gas analysis results at the end of the experiments are shown in Table 1. The alveolar-arterial (A-a) oxygen gradient was high after 8 hours of MV in both groups (Table 1). During 8 hours of MV, 30% of the animals in the MV LPS group died (n = 5; respectively, 4 hours, 5 hours and 5½ hours, and two mice died after 6 hours of MV). In the levosimendan-treated group, 12% (n = 2) died before the
end of the planned duration of MV (after 5 and 7½ hours of ventilation, respectively; \( P = 0.2 \) between groups). Animals that did not survive until the end of the study were excluded from further biochemical analysis. Accordingly, 8 CON mice, 12 MV LPS mice and 14 MV LPS + L mice were included for biochemical analysis.

**Nitrosative and oxidative stress**

To investigate the effects of levosimendan on nitrosative and oxidative stress in endotoxemic, mechanically ventilated mice, diaphragms were analyzed for iNOS expression, protein nitrosylation and HNE protein concentration. Diaphragm iNOS expression was significantly increased by 274% in LPS-exposed, ventilated mice (\( P < 0.05 \) versus CON) (Figure 2A). Unexpectedly, levosimendan enhanced the expression of iNOS by 47% (Figure 2A) (\( P < 0.05 \) for MV LPS versus MV LPS + L), but decreased diaphragm protein nitrosylation by 10% (Figure 2B,C) (\( P < 0.05 \) for MV LPS versus MV LPS + L). Diaphragm HNE protein concentration was not significantly different between MV LPS and CON animals. Levosimendan decreased the amount of HNE proteins in the diaphragm by 13% compared with MV LPS (Figure 2D,E) (\( P < 0.05 \) for MV LPS versus MV LPS + L).

**Inflammation**

In MV LPS mice, proinflammatory cytokines were significantly upregulated in diaphragm muscle and plasma (Figures 3 and 4). Levosimendan did not affect this inflammatory response.

**Caspase-3 and E3 ubiquitin ligases**

Caspase-3 and the E3 ubiquitin ligases MuRF1 and MAFbx were analyzed as measures of muscle proteolysis. No differences in caspase-3 activity or MuRF1 mRNA were observed between groups. MAFbx expression was significantly increased in MV LPS and MV LPS + L animals compared with controls (ratios to GAPDH: 27 ± 12 for CON, 102 ± 35 for MV LPS and 114 ± 47 for MV LPS + L). Levosimendan did not affect expression of MAFbx in ventilated endotoxemic mice.

**Discussion**

The main findings of the present study are that (1) levosimendan decreased protein nitrosylation and markers of oxidative stress in the diaphragm of endotoxemic mechanically ventilated mice, but that (2) levosimendan did not attenuate diaphragmatic and systemic inflammatory responses, diaphragmatic iNOS and E3 ubiquitin ligase expression or caspase-3 activity.

| Table 1 Arterial blood gas and alveolar-arterial gradient after 8 hours of mechanical ventilation and endotoxemia exposure* |
|-----------------|---------|----------|--------|-------|---------|-----------------|
|                 | pH      | \( \text{PaO}_2 \) (mmHg) | \( \text{PaCO}_2 \) (mmHg) | \( \text{HCO}_3 \) (mmol/L) | \( \text{BE} \) (mEq/L) | A-a gradient (mmHg) |
| MV LPS + L      | 7.23 ± 0.0 | 153 ± 11 | 26 ± 1.3 | 11 ± 0.8 | −16.6 ± 1.0 | 135 ± 9.4 |
| MV LPS         | 7.24 ± 0.0 | 153 ± 14 | 25 ± 2.5 | 12 ± 1.0 | −15.7 ± 1.3 | 136 ± 8.3 |

Effects of endotoxemia and mechanical ventilation on the diaphragm

LPS in rodents is a widely used model to study the effects of endotoxia on organ function, including respiratory muscles [28-31]. We found increased expression of iNOS in the diaphragm of these animals. This is in line with the only previous study in which researchers investigated a combination of endotoxemia and MV, where diaphragm weakness was associated with elevated levels of iNOS protein [10]. In addition, in the present study, proinflammatory cytokines were upregulated in the diaphragm of endotoxemic ventilated animals. This inflammatory response is consistent with earlier experimental models of either MV or endotoxia [16,31,32]. MV and endotoxia are known to increases proteolysis in the diaphragm, as supported by, for example, elevated caspase-3 activity and expression of the E3 ubiquitin ligases MuRF1 and MAFbx [5,33-35]. Expression of MAFbx was also enhanced in our endotoxemic ventilated mice. MuRF1 expression and caspase-3 activity were not elevated in endotoxemic ventilated mice. This suggests that the proteolytic response to a combination of MV and endotoxia is weaker than that to MV or endotoxia separately. Reduced proteolysis could preserve diaphragmatic function. This is supported by findings in a previous study in rats [10], where MV was shown to partly prevent the development of diaphragmatic dysfunction during endotoxia. However, it should be acknowledged that, in the present study, the effect of MV solely on the diaphragm was not evaluated, as this was not required to test the hypothesis of the study.
It has been shown previously that endotoxemia is associated with pulmonary inflammation and elevates the A-a oxygen gradient [36]. In line with those observations, we found a high A-a gradient in endotoxemic ventilated mice (Table 1). The A-a gradient was not assessed in control mice in the present study. We have previously shown that the A-a oxygen gradient in healthy mice ventilated for 8 hours was higher than normal (79 ± 21 mmHg) [16], but it was significantly lower than reported in the present study for LPS-exposed ventilated mice. This indicates that systemic effects of LPS further impaired oxygen uptake in the endotoxemic ventilated groups of the present study.

Effects of levosimendan

Among its inotropic effects through calcium sensitization, levosimendan has been shown to affect several intracellular pathways involved in oxidative stress and inflammation [21,23]. In the present study, levosimendan infusion decreased nitrosylated protein levels in ventilated endotoxemic mice (Figure 2B). Peroxynitrite formation is one of the chemical reactions involved in the nitrosylation of tyrosine residues in proteins (Figure 5) [37,38]. Peroxynitrite is an extremely reactive free radical generated from the reaction between nitric oxide and superoxide [39]. Nitric oxide is synthesized from L-arginine under the influence of the three NOS enzymes: iNOS, endothelial NOS and neuronal NOS [40].

In the present study, levosimendan did not reduce iNOS expression (Figure 2A) in the diaphragm of mechanically ventilated endotoxemic animals. This may suggest that levosimendan reduced peroxynitrite formation by lowering superoxide levels. Decreased superoxide levels are expected to be accompanied by a reduction of markers for oxidative stress. In line with that assumption, HNE protein levels (a marker for oxidative stress) were decreased in the diaphragm of levosimendan-treated mice (Figure 2D). In accordance with the possible ability of levosimendan to reduce oxidative stress, a recent investigation showed that levosimendan treatment increased protective antioxidant enzyme levels in renal tissues of rats [41]. Myeloperoxidases can induce tyrosine nitrosylation independently of peroxynitrite formation (Figure 5) [42]. Interestingly, previous experimental studies have shown that levosimendan
reduces myeloperoxidase activity in the heart and spinal cord [43,44], but this has not been investigated in the diaphragm. Although we did not specifically investigate this pathway, we cannot exclude the possibility that levosimendan decreased protein nitrosylation by reducing myeloperoxidase activity.

In the present study, levosimendan did not attenuate the proinflammatory response to endotoxemia and MV in either plasma or the diaphragm (Figures 3 and 4). The lack of effect of levosimendan on plasma inflammation after levosimendan exposure is in line with previous studies [45,46]. In apparent contrast, in experimental sepsis induced by cecal ligation and incision, levosimendan did reduce high plasma levels of IL-1β [24]. However, in our animal model, plasma levels of IL-1β were not elevated after LPS exposure. Furthermore, levosimendan did not dampen MAFbx expression in endotoxemic ventilated mice. Interestingly, IL-6 is a well-known regulator of MAFbx gene expression [47]. The absence of an effect of levosimendan on plasma and diaphragmatic IL-6 levels could provide an explanation for the absence of a dampened effect of levosimendan on MAFbx expression. The activation of caspase-3, another essential player in muscle protein degradation, was reduced in the spleen of septic animals treated with levosimendan [24]. Also, in cardiac muscle cells, levosimendan could protect against hydrogen peroxide–induced caspase-3 activation [23]. In the present study, caspase-3 activity in the diaphragm was unchanged by levosimendan, but was not enhanced by endotoxemia and MV.

**Study limitations**

The present study has limitations that should be acknowledged. First, the duration of MV and endotoxemia in the present study was relatively shorter than is usually the case in critically ill patients. It should be noted that MV in mice is challenging because of limited possibilities of vital function monitoring and the fact that, owing to very low intravascular volume (approximately 2 ml), no repetitive samples can be withdrawn for blood gas analysis. Nevertheless, in the present study, 8 hours of MV resulted in modulation of important biochemical pathways in the diaphragm, in line with the results of our previous study [16]. Therefore, this time period is appropriate for study...
of the effects of levosimendan on activation of inflammatory and proteolytic pathways. A second limitation of our study is that we did not assess the effects of levosimendan on diaphragm muscle function. Previously, we have shown that levosimendan improves diaphragm muscle function, both in vitro and in vivo, in healthy subjects, in patients with COPD and in animal models of congestive heart failure [18,19,48]. We can only speculate that it also will improve diaphragm function in the current model, but this should be confirmed in future studies. Third, as MV of endotoxemic mice is technically challenging, we were reluctant to invasively monitor cardiac output or tissue perfusion, which is of potential interest because levosimendan has been shown to both improve cardiac output and induce vasodilation [20]. Fourth, in the present study, LPS was used to induce an inflammatory response, and LPS administration to animals has been proven to be a predictable model of systemic inflammation [49]. However, it should be acknowledged that this is a model of systemic inflammation and does not necessarily reflect the physiological processes observed in human septic shock.

**Conclusions**

In an animal model of endotoxia and MV, levosimendan decreased markers of oxidative and nitrosative stress. Therefore, our data may suggest that the beneficial effects of levosimendan in clinical trials [20,50] may partly result from effects beyond calcium sensitization. The present study provides a rationale for investigating such a mechanism in a clinical study. In a current randomized clinical trial (ClinicalTrials.gov identifier NCT01721434), we are investigating levosimendan in patients difficult to wean from the ventilator.

**Key messages**

- Levosimendan dampens nitrosative stress in the diaphragm of mechanically ventilated endotoxemic mice.
- Levosimendan did not attenuate diaphragmatic inflammation following 8 hours of MV in endotoxemic mice.
