1 MEDICINE USE AND MEDICINE RELATED PROBLEMS IN PATIENTS WITH LIVER CIRRHOSIS: A SYSTEMATIC REVIEW OF QUANTITATIVE AND QUALITATIVE STUDIES

Ejaq Cheema, Abdullah Al-Hamid, Alaa Al-Aryan. University of Birmingham; School of Health and Social Care, University of Hertfordshire

Introduction Liver cirrhosis is a major chronic disease that is associated with high morbidity and mortality. The associated co-morbidities and medical complications together with the use of complex and multiple drug therapies by patients with liver cirrhosis put them at an increased risk of developing medicine related problems (MRPs). MRPs can be defined as an event or circumstance involving drug therapy that actually or potentially interferes with desired health outcomes. This review aims to systematically investigate the prevalence, causes and risk factors of MRPs in cirrhotic patients and to explore factors influencing the medicine use from the perspective of patients and health care providers’ perspectives.

Subjects and methods Eight online databases (PubMed, Scopus, CINAHL, The British library, PsycINFO, Web of Science, EMBASE, and Google scholar) were searched up to 30th Sep, 2018 with no start date. Both quantitative studies including randomised controlled trials (RCTs), clinical trials and observational studies as well as qualitative studies were included in the review. Search terms used included ‘medicine related problems’, ‘medicine use’, ‘patients’ perceptions’ and ‘adverse drug reaction’. Data collected included the study design, baseline characteristics of study population and study outcomes. Appropriate Critical Appraisal Skills Programme (CASP) tools were used to assess both the quality of quantitative studies as well as qualitative studies. An in-depth descriptive analysis of the quantitative data and a thematic analysis of the qualitative data were undertaken.

Result 16 quantitative studies and 11 qualitative studies were included in the review. Of the 16 quantitative studies, nine examined the prevalence, causes, risk factors and medicine classes associated with MRPs and the remaining seven studies reported factors affecting medicine use. Mean frequency of MRPs reported in the quantitative studies ranged from 14%–23.4%. The most frequent causes of MRPs identified in the studies included drug interactions, inappropriate dosing and use of contraindicated drugs. Major risk factors associated with MRPs included polypharmacy, severity of liver disease and length of hospital stay. Diuretics, analgesics and sedatives were suspected to be among the most common drug classes associated with MRPs. The thematic synthesis of qualitative data identified three key themes: patient related factors including lack of patients’ knowledge about liver cirrhosis and its risk factors; health care related factors including lack of communication between healthcare professionals and patients; stigma and negativity including negative attitudes (misconceptions and discriminations) and negative consequences of liver cirrhosis.

Conclusions MRPs pose a significant social and financial burden on both patients and healthcare systems. Findings of this review suggest that the management of liver cirrhosis should not only be limited to the provision of safe and effective drug therapy but should also expand to improving the understanding and awareness of patients about the disease. Future research should focus on assessing the impact of patient-specific education on medicine use by patients with liver cirrhosis.

2 POMPHOLYX – A RARE SIDE EFFECT OF TRASTUZUMAB

Abubakkar Raheel, Syed Irfan Wafa, Anupama Gore. University Hospitals of Leicester, Leicester Royal Infirmary

Background Trastuzumab is a monoclonal antibody prescribed as part of systemic treatment of breast cancer. Trastuzumab can be prescribed on its own or as an adjuvant with chemotherapy or hormone therapy against over-expressing HER2 positive breast cancer. Patients on Trastuzumab can develop side effects of nausea, vomiting, cardiotoxicity and flu-like symptoms. However, we describe a rare side effect of Pompholyx (dyshidrotic eczema). This may be the first case of this presentation to be reported.

Case presentation A 50-year-old Caucasian female with a Background of 3 mm invasive ductal carcinoma of left breast presented with extensive vesicles and blistering on palms of hands and feet following treatment with trastuzumab [figure 1]. She had wide local excision of a 3 mm invasive ductal carcinoma of left breast in January 2018 and sentinel lymph node biopsy which revealed a grade 2, HER2 positive, node negative, breast cancer. She received 6 cycles of adjuvant chemotherapy with epirubicin and cyclophosphamide followed by 15 fractions of 40 Gy adjuvant radiotherapy. Thereafter she was commenced on targeted therapy with trastuzumab. After the 2nd cycle of trastuzumab she developed multiple small vesicular eruptions predominantly on the hands and feet, which worsened by the 3rd cycle. These were diagnosed by a dermatologist as extensive pompholyx, which was treated with topical steroid, emollient, potassium permanganate and fluorocortisone tape on the palms. Her swab cultures grew Staphylococcus aureus and beta-hemolytic streptococcus group-A, which was subsequently treated with intravenous flucloxacillin with a modest response.

Discussion Trastuzumab is a humanized monoclonal antibody that blocks HER2 receptors, undermining HER2 signaling in HER2 over-expressing breast cancers. The pathogenesis of pompholyx is not well understood thus it is difficult to establish a direct connection with trastuzumab at this stage. According to some immunohistochemistry studies, strong presence of CD3, CD8, CD45 as well as anti-human antibodies are found in pompholyx whereas an immune mediated T-Cell lymphocyte-driven response in suppressing tumor growth in cancer has extensively been described. We plan to

biopsy the lesions and subsequently monitor her response to steroids with continuation of trastuzumab, since benefits of trastuzumab outweigh the risks of eczema.3

Conclusions We report the first case of trastuzumab therapy presenting with extensive infected pompholyx (dyshidrotic) eczema in a breast cancer patient. Although the patient described a history of a mild eczema five years previously, an acute flare while undergoing treatment could certainly be added to conditions at risk of flare during trastuzumab therapy until this is proven as a clear trastuzumab side effect through meta-analysis of multiple studies and a comprehensive dataset.

3 EVALUATION OF HO-1 INVOLVEMENT IN MELANOMA RESISTANCE TO BRAF INHIBITOR VEMURAFENIB

Giulia Loi, Annalisa Furfaro, Maria Adelaide Pronzato, Gabriella Pietra, Mariapaola Nitti. Department of Experimental Medicine. Section of General Pathology, University of Genoa, Via Leon Battista Alberti, 2 16132 Genova (GE), Italy. 10.1136/postgradmedj-2018-fpm.14

Introduction The point mutation of the BRAF gene (BRAFV600E) is present in more than 50% of melanoma.

This mutation determines the continuous activation of MAPK pathway, which favours cell survival and proliferation. Vemurafenib/PLX4032 (PLX4032) is an inhibitor of BRAFV600 for the therapy of these tumours, but, after an initial positive response, in many cases a relapse of the disease occurs. HO-1 is the inducible form of heme oxygenase and overexpression is involved in the growth and resistance to therapy of different types of tumours. In this study we have evaluated the involvement of HO-1 in chemoresistance and angiogenesis of BRAFV600E primary melanoma cells.

Materials and methods We used a primary melanoma cell line, derived from a metastasis from a patient, and exposed cells to PLX4032 (1–10 μM). The role of HO-1 was studied by gene silencing or using the pharmacological inhibitor of HO-1 tetracosoporphyrin IX (SnMP-IX), a drug used to treat hyperbilirubinemia. Angiogenic potential was evaluated by using bovine aortic endothelial cells (BAEC) isolated in our laboratory.

Results Primary melanoma cells (MeOV-1) were exposed to 1–10 μM PLX4032 for 24 hour. MTT and Trypan blue assays showed a reduction in cell viability of 45% and immunoblot and qRT-PCR analyses revealed a significant upregulation of HO-1 expression. HO-1 silencing or exposure to 10 μM SnMP-IX further decreased cell viability after exposure to PLX4032. Subsequently, we evaluated the angiogenic potential of melanoma cells. Medium derived from McOV-1 cells, exposed to 10 microl PLX4032, was used to treat BAEC seeded on Matrigel. Tube formation, branching and density were increased in comparison to BAEC exposed to the medium from untreated MeOV-1 cells. Interestingly, when BAEC were treated with conditioned medium from MeOV-1 cells and HO-1 was silenced, 10 μM PLX4032 showed a reduced ability to form tubes.

4 WHICH INTENSIVE CARE ANALYTICS ARE A WORTHWHILE INVESTMENT FOR DEVELOPERS? AN EARLY HEALTH TECHNOLOGY ASSESSMENT

Lytske Bakker, Jos Aarts, Ken Redekop. Erasmus School of Health Policy and Management, Erasmus University. 10.1136/postgradmedj-2018-fpm.15

Introduction In intensive care (IC), monitoring data are continuously being collected. Unfortunately, this data is often not interpretable for clinicians and therefore goes unused. While advanced analytics can process this data to support improvements in patient care, developers ideally invest in those analytics that lead to the greatest health benefits or cost reductions. We explored the potential cost-effectiveness of three IC analytics.

Subjects and methods We assessed the cost-effectiveness of three applications: the early identification of catheter-related bloodstream infection (CRBSI), improved nutrition monitoring and identification of high driving pressure (HDP) in ventilated patients. The literature was used to populate the decision trees and patient data from a Greek IC were used for the nutrition and HDP analytics. We performed univariate, multivariate, and probabilistic sensitivity analyses.

Results Early identification of CRBSI reduced mortality and length of stay, thereby increasing quality-adjusted life-years (QALYs) (6.70 vs. 6.58) and reducing costs (£8183 vs. £9,869); probability of CRBSI and the costs per IC day were key influences of the ICER and the probability of dominance was 90%. Improved nutrition monitoring could increase nutrition adherence (0.37% vs. 0.03%) and decrease costs by reducing length of stay (£9988 vs. £10,720). For HDP, benefits were limited, resulting in higher costs as well as minimal and highly uncertain health benefits.

Conclusions Developers should study the potential impact of the analytics they wish to develop before investing time and money. We illustrate that analytics for early identification of CRBSI and improved nutrition monitoring are worth further investment while identifying HDP may not be. The other factors that influence success besides health and financial benefits such as the competition and data access should be assessed.
