Subspecialty Virtual Impact Factors within a Dedicated Neuroimaging Journal

A.F. Choudhri and M. Castillo

ABSTRACT

BACKGROUND AND PURPOSE: The growing number of subspecialties within neuroradiology compete for pages in neuroradiology journals. We performed a bibliometric analysis of the American Journal of Neuroradiology to identify the virtual Impact Factor of different journal subsections and article topics.

MATERIALS AND METHODS: Original Research and Review Articles published in American Journal of Neuroradiology during 2010–2012 were evaluated. The journal section for each article was recorded, and the number of citations was evaluated by using the Web of Science database. Numbers of citations within the first 2 years after publication were evaluated, normalized to the 2013 journal Impact Factor (for American Journal of Neuroradiology, 3.675), and used to calculate a virtual Impact Factor for different journal subsections.

RESULTS: One thousand forty-nine Original Research and Review Articles were published during this time, which obtained an average of 6.59 citations each within their first 2 years after publication; 91.8% of articles obtained at least 1 citation. Expedited Publications had the greatest number of citations, averaging 43.7 citations each (virtual Impact Factor, 24.39), followed by Review Articles averaging 9.39 citations each (virtual Impact Factor 5.23). Virtual Impact Factors for other sections were the following: Interventional, 4.54; Brain, 3.70; Pediatrics, 2.91; Functional, 2.74; Head & Neck, 2.24; and Spine, 1.86. Virtual Impact Factors for article topics were the following: Interventional, 4.75; Functional/Advanced, 3.79; Brain, 3.66; Pediatrics, 2.99; Head and Neck, 2.46; and Spine, 2.32.

CONCLUSIONS: Citation patterns of Original Research and Review Articles in American Journal of Neuroradiology varied widely on the basis of subsections. Understanding the citation patterns of specific topics and subsections of a journal may aid authors and editors in evaluating the appropriate balance among various topics and allow authors to determine whether their articles are being cited at a level expected for similar ones in a journal.

ABBREVIATIONS: JIF = journal Impact Factor; VIF = virtual Impact Factor

Citation analysis is an important means of evaluating the performance of journals and of authors, with implications regarding promotions, grant funding, advertising sales, and library selections. The growing number of subspecialties within neuroradiology compete for journal pages, and citation profiles of these different subsections have not been evaluated. We performed a bibliometric analysis of American Journal of Neuroradiology (AJNR) to identify citation patterns based on subsections and article topics.

Neuroradiology encompasses evaluation of the brain, head and neck, spine, and peripheral nervous system, including minimally invasive diagnostic and therapeutic techniques in these areas. Several journals dedicated to neuroradiology exist; however, neuroradiologic articles are also included in general radiology journals and in radiology subspecialty journals such as those dedicated to pediatric radiology. While there is a growing body of bibliometric analyses in the radiology literature, few studies have focused on neuroradiology topics to date.

We hypothesized that the citation characteristics of a journal are heterogeneous among journal subsections and varying topics. We undertook a bibliometric analysis to evaluate the citation characteristics of neuroradiology articles within a neuroradiology journal.
Citations from noncategorized items, including letters to the editor, editorials, and errata, were not included in the VIF calculation. Each article selected for analysis was reviewed in the Web of Science database to determine how many citations it received. While we could find no existing bibliometric reports formally documenting this methodology, we believe that using the average number of citations for each journal subsection is a valid extension of the reported methodology of the JIF.11–14

Statistics
Data were collected in a spreadsheet (Excel; Microsoft, Redmond, Washington), and statistics were calculated by using SPSS Version 21 (IBM, Armonk, New York) and Excel. Discrete variables (number of articles with zero versus greater than 1 citation) were compared using the Fisher exact test. Continuous variables (number of citations, VIF) were compared with a Student t test when there was a Gaussian distribution of data and otherwise with the nonparametric Wilcoxon rank sum test. P values < .05 were considered significant.

RESULTS
One thousand forty-nine Original Research and Review Articles were published in AJNR during the 3 years evaluated. An additional 77 uncategorized items, including editorials, letters to the editor, and errata, were excluded from analysis. The 1049 categorized articles accumulated 6.59 ± 8.53 (range, 0–116; median, 4) citations within their first 2 years after publication, and 91.8% of articles had at least 1 citation. On the basis of a JIF of 3.675, the VIF for a given section was determined as (Number of Citations / (6.59 / 3.675)).

Citations by Journal Section
Expedited Publications had the most citations with 11 articles averaging 43.7 ± 31.9 (range, 13–116; median, 36) citations each (VIF, 24.39). Review Articles had the next highest number of citations, with 53 articles averaging 9.38 ± 7.95 (range, 0–38; median, 7) citations each (VIF, 5.23), and 52 (98.1%) of these articles received at least 1 citation within 2 years of publication. VIFs for other sections ranged from 4.54 for Interventional (the highest) to 1.86 for Spine (the lowest) (Table 1). Articles selected as “Editor’s Choices” had a VIF of 5.14, and those selected for the “Fellows’ Journal Club” had a VIF of 3.83.

Citations by Article Topic
When we evaluated the citation characteristics by article topic as opposed to journal-assigned categories, Interventional articles had the highest citation numbers, averaging 8.52 ± 12.54 (range, 0–116; median, 5) citations with a VIF of 4.75, which was similar to the journal category of Interventional (P = .69) (Table 2). Articles related to the spine were cited 4.16 ± 3.69 (range, 0–19;
median, 3) times, with a VIF of 2.32, which was higher than the Spine category of the journal (P = .074). The percentage of articles having at least 1 citation within 2 years of publication ranged from 82.4% for Head & Neck articles (108 of 131) to 100% for Expedited Publication (11 of 11).

**Number of Articles Receiving at Least 1 Citation**

The number of publications receiving at least 1 citation within 2 years was statistically lower for the Head & Neck category compared with Review Articles (P = .003), Interventional (P = .0003), Brain (P = .0003), and Pediatrics (P = .0042). The number of publications receiving at least 1 citation within 2 years was statistically lower for the Spine category than Review Articles (P = .0103), Interventional (P = .0053), Brain (P = .0075), and Pediatrics (P = .028).

**DISCUSSION**

Citation patterns of Original Research and Review Articles in AJNR varied widely on the basis of subsections, with Review Articles accumulating the greatest number of citations within the first 2 years after publication. Understanding these citation patterns for specific topics and subsections of a journal may aid editors in evaluating the appropriate balance between topics and allow authors to determine whether their articles are being cited at levels expected for similar topics in a journal.

The highest number of citations was for articles classified as “Expedited Publication,” which is not unexpected because these are presumably important and timely topics. Thus, encouraging the submission of such articles has the potential to influence the Impact Factor of a journal. Expedited peer review and waived fees, such as those for color figures or article length, may be ways to encourage such submissions as AJNR does.

Articles that received the designation of “Editor’s Choice” and “Fellows’ Journal Club” were cited more often than others in their given journal categories. These designations are chosen by the Editor-in-Chief, and it is possible that the assigned designations improved recognition of the articles and resulted in increased citations. In addition, the articles chosen for these categories are usually those with state-of-the-art topics, clinically important, and of higher evidence-based levels, which may also contribute to their increased citations. Articles related to spine intervention trended toward a higher number of citations than diagnostic spine articles overall, probably because they are viewed and cited by specialists outside of just imaging.

Limitations in our study include the inability to determine the exact parameters that compose the official JIF because this is a proprietary algorithm that is modified with time. Additionally, the JIF changes with time, and we only used a single JIF for this investigation, the 2013 JIF, which was the most recent one available at the time of analysis. As with all citations, it is not possible to determine citations when the original article serves as a foundation for future work or when it is criticized or refuted. Many articles are well-received by readers, becoming popular reading but are not cited. One of the reasons many journals have decreased or eliminated case reports, despite their popularity among readers, is the negative effect on the JIF. We created our VIF on the basis of citations in the first 2 years after publication, mirroring the methodology of the JIF. The JIF also can be calculated for other periods of citations, in particular the 5-year JIF, which may give additional information about the longevity of impact of an article; however, we chose to perform a 2-year analysis because the 2-year JIF is the most commonly used metric.

The resultant quality of articles in a journal is a factor of the quality of work being performed in a given area, the alternative outlets for publication that a given author may choose, and the quality of the editorial review process. It is possible that areas such as intervention, in which many reviewers practice for a large percentage of their careers, receive higher quality reviews because the reviewers want to simultaneously select the best articles and provide the best feedback to the authors during the review process to improve the articles. In contrast, a smaller number of radiologists have most of their practice in head and neck and likely even fewer have their practice and academic interests primarily in spine.

Beyond neuroradiology journals, there are spine-focused journals in neurosurgery and orthopaedic surgery (eg, *Journal of Neurosurgery–Spine*, and *Spine*). These 2 journals have JIFs of 2.355 and 2.447, respectively, very similar to the 2.319 VIF for articles with a spine topic in *AJNR*. Comparisons such as this may help determine whether subsections and/or topics are being cited like those in journals with a potentially overlapping focus.

Knowledge of subsection VIF may allow prediction of the influence on the JIF, with reallocation of journal pages between sections. Page allotment limitations from print journals may be mitigated as they shift toward on-line publications.

Because the financial and logistic barriers for creating larger new journals has decreased, it may be tempting for physicians with a narrow area of interest to contemplate creation of a focused journal on a given topic, and understanding citation trends may provide evidence that a narrowly focused journal may or may not have the ability to survive. For example, it is clear from our investigation that for subspecialties such as spine and head and neck

| Topic                  | No.  | Mean | SD   | Minimum | Maximum | Median | % with Citations in First 2 Years | VIF  |
|------------------------|------|------|------|---------|---------|-------|----------------------------------|------|
| Interventional         | 317  | 8.52 | 12.54| 0       | 116     | 5     | 0.927                            | 4.753 |
| Functional/advanced    | 199  | 6.80 | 5.49 | 0       | 36      | 6     | 0.965                            | 3.791 |
| Brain                  | 484  | 6.57 | 6.28 | 0       | 61      | 5     | 0.940                            | 3.663 |
| Pediatrics             | 115  | 5.36 | 5.12 | 0       | 36      | 4     | 0.930                            | 2.987 |
| Head and neck          | 189  | 4.42 | 4.46 | 0       | 34      | 3     | 0.868                            | 2.463 |
| Spine                  | 145  | 4.16 | 3.69 | 0       | 19      | 3     | 0.883                            | 2.319 |
| Editor’s Choice        | 83   | 9.22 | 9.75 | 0       | 61      | 6     | 0.976                            | 5.139 |
| Fellows’ Journal Club  | 82   | 6.87 | 5.72 | 0       | 31      | 6     | 0.902                            | 3.828 |
| Nonvascular intervention | 122 | 6.07 | 5.78 | 0       | 34      | 4.5  | 0.918                            | 3.387 |
| Peds head and neck     | 17   | 4.94 | 3.42 | 0       | 11      | 4     | 0.941                            | 2.755 |
| Spine interventional   | 64   | 4.14 | 3.37 | 0       | 15      | 7     | 0.891                            | 2.309 |

Note:—Peds indicates Pediatrics.

*a* “Fellows’ Journal Club” and “Editor’s Choices” are journal designations that are independent of the journal-selection category.
imaging, creating their own freestanding journals may be difficult and physicians are better served by remaining within a larger journal with a higher JIF than they would in independent journals dedicated to their specialty. In addition, authors of articles with a given topic may be able to better recognize the expected citations of their article and whether submitting to a specific journal such as AJNR is best for them. For instance, the author of a diagnostic spine imaging article in AJNR, which will have fewer citations than the average article in the journal, may be less discouraged if they know their article has been cited more than other diagnostic spine articles in the same or other journals. Thus, encouraging all journals to calculate and publish their virtual JIF by sections may be useful to prospective authors.

CONCLUSIONS
Understanding the citation expectations of specific topics and subsections of a journal may aid editors in evaluating the appropriate balance among various topics and allow authors to determine whether their article is being cited at a level expected for similar topics in a journal.
