Probing the Planck scale: the modification of the
time evolution operator due to the quantum structure
of spacetime

ABSTRACT: The propagator which evolves the wave-function in non-relativistic quantum mechanics, can be expressed as a matrix element of a time evolution operator: i.e. \( G_{NR}(x) = \langle x_2 | U_{NR}(t) | x_1 \rangle \) in terms of the orthonormal eigenkets \( |x\rangle \) of the position operator. In quantum field theory, it is not possible to define a conceptually useful single-particle position operator or its eigenkets. It is also not possible to interpret the relativistic (Feynman) propagator \( G_R(x) \) as evolving any kind of single-particle wave-functions. In spite of all these, it is indeed possible to express the propagator of a free spinless particle, in quantum field theory, as a matrix element \( \langle x_2 | U_{R}(t) | x_1 \rangle \) for a suitably defined time evolution operator and (non-orthonormal) kets \( |x\rangle \) labeled by spatial coordinates. At mesoscopic scales, which are close but not too close to Planck scale, one can incorporate quantum gravitational corrections to the propagator by introducing a zero-point-length. It turns out that even this quantum-gravity-corrected propagator can be expressed as a matrix element \( \langle x_2 | U_{QG}(t) | x_1 \rangle \). I describe these results and explore several consequences. It turns out that the evolution operator \( U_{QG}(t) \) becomes non-unitary for sub-Planckian time intervals while remaining unitary for time interval is larger than Planck time. The results can be generalized to any ultrastatic curved spacetime.

1 Motivation

1.1 Propagators in non-relativistic quantum mechanics and quantum field theory
Consider a non-relativistic free particle with the Hamiltonian $H = p^2/2m$. Its quantum dynamics can be completely characterized by the propagator

$$G_{\text{NR}}(x_2, x_1) = \theta(t) \left( \frac{m}{2\pi i t} \right)^{n/2} \exp \left( \frac{im |x|^2}{2t} \right); \quad x \equiv x_2 - x_1 \quad (1.1)$$

The $\theta(t)$ in eq. (1.1) is somewhat conventional so that $G$ satisfies the equation $(i\partial_t - H)G_{\text{NR}} = \delta_D(t)$ with a Dirac delta function on the right hand side. This factor is also consistent with the feature that, when $G_{\text{NR}}(x)$ is computed using a path integral, we only sum paths which go forward in time. But since non-relativistic Schrodinger equation is

---

1 Notation: I work in $1 + 3$ dimensions for definiteness, though the results can be trivially extended to $1 + d$ dimensions. Latin indices run over 0-3 while the Greek indices run over 1-3. I will use $x' = (t, \mathbf{x})$ to denote the coordinates of an event even while discussing non-relativistic quantum mechanics (NRQM). The superscript $i$ etc. in $x'_i, x'_I$ will be often omitted and I will just write $x_2, x_1$ etc. for notational simplicity. The signature is mostly negative.
first order in the time derivative, one can use the same propagator — without the $\theta(t)$ factor — to evolve the wave-function (either forwards or) backwards in time; i will stick to the convention in eq. (1.4) to define $G_{NR}$. (Nothing goes wrong in NRQM if the $\theta(t)$ is omitted.)

For this propagator to consistently propagate the Schrodinger wave-functions, it must satisfy two crucial algebraic conditions:

$$\lim_{t_b \to t_a} G_{NR}(x_b, x_a) = \delta_D(x_b - x_a) \quad (1.2)$$

$$G_{NR}(x_b, x_a) = \int d^n x_1 \ G_{NR}(x_b, x_1) \ G_{NR}(x_1, x_a) \quad (1.3)$$

One can directly verify from the explicit form of eq. (1.1) that these conditions do hold. The second condition eq. (1.3), viz. the transitivity, is a strong constraint and is closely related to the fact that both wave-functions, and the propagator, satisfy a differential equation which is first order in time.

The NRQM propagator can be related to the Hamiltonian\footnote{This holds even for systems more general than free particle; but I will be only concerned with the free particle.} by expressing it as the matrix element of a time evolution operator in the form:

$$G_{NR}(x) = \theta(t)|x_2\rangle U_{NR}(t)|x_1\rangle; \quad U_{NR}(t) = e^{-itH} \quad (1.4)$$

where $x = x_2 - x_1$. Expressed in this form, the property in eq. (1.2) demands the orthonormality of the kets: $\langle x|y \rangle = \delta_D(x - y)$ while the property in eq. (1.3) requires two conditions: (i) the completeness of the kets $|x\rangle$ which allows the identity operator to be expressed as an integral over $d^3x \langle x|\langle x|$ and (ii) the composition law for the evolution operator $U(t_1)U(t_2) = U(t_1 + t_2)$.

Let us move on from NRQM to the QFT of a massive, free, spinless particle. In standard QFT, the (somewhat trivial) dynamics of the free field is entirely captured by the Feynman propagator $G_R(x)$ given by any one of these expressions:

$$G_R(x) = \frac{1}{i} \frac{1}{16\pi^2} \int_0^\infty \frac{ds}{s^2} \exp\left(-\frac{x^2}{4s} + m^2s\right) \quad (1.5)$$

$$= \int \frac{d^4p}{(2\pi)^4} \frac{i e^{-ipx}}{p^2 - m^2 + i\epsilon} \quad (1.6)$$

$$= \int \frac{d^3p}{(2\pi)^3(2\omega_p)} e^{ip\cdot x - i\omega_p|t|} \quad (1.7)$$

Equation (1.5) is the Schwinger’s proper time representation of the propagator and is the most elegant way of describing it; this will be our work-horse in the later sections. Equation (1.6) is the more familiar expression for the Feynman propagator used in practical computations, which can be obtained by the 4-dimensional Fourier transform of eq. (1.5) with respect to $x^4$. Similarly, eq. (1.7) can be obtained by a 3-dimensional Fourier transform of eq. (1.5) or by a more familiar route of integrating over $p^0$ in eq. (1.6) using standard contour integration techniques (See section 1.4 of ref. [1]).
Equation (1.5) and eq. (1.6) are manifestly Lorentz invariant; one can show [1] that eq. (1.7) is also Lorentz invariant in spite of the occurrence of $|t|$. To ensure convergence of the $s$ integral in eq. (1.5), we need to interpret $m^2$ as $m^2 - i\epsilon$ and $x^2$ as $x^2 - i\delta$. (Adding a negative imaginary part to $m^2$ is a well known prescription. But note that, to ensure convergence near $s = 0$, we need to add a negative imaginary part to $x^2$ as well. This is obvious when we consider the massless case and it ensures picking up the correct singular structure on the light cone.) I will not explicitly display $i\epsilon$ and $i\delta$ except when it is relevant to the discussion. Any of the integrals in eq. (1.5)–eq. (1.7) can be explicitly evaluated in terms of modified Bessel functions to give the result

$$G(x_2; x_1) = \frac{m}{4\pi^2 i \sqrt{x^2}} K_1(im \sqrt{x^2})$$

(1.8)

We will not need this explicit form for most of our discussion.

As an important aside, let me stress that I have not used the definition of propagator as the vacuum correlator of time ordered quantum fields. This is completely intentional. In the later sections I will discuss the form of the propagator close to Planck scales. I want to work with a descriptor of the quantum dynamics (of spinless particle of mass $m$) which is robust enough to survive (and be useful) close to Planck scales. The propagator is a good choice for such a description because it is possible to define it without using the notion of a local quantum field operator, commutation rules, vacuum state etc.. In appendix A, I mention three such definitions for the benefit of readers who tend to always associate propagators with time-ordered correlators of quantum field. None of the definitions in appendix A use the formalism of a local field theory and its canonical quantisation, notions which may not survive close to Planck scales.

In contrast to $G_{NR}$, the relativistic propagator does not satisfy the two conditions in eq. (1.2) and eq. (1.3). It satisfies a differential equation which is second order in time:

$$\left(\partial^2_t - \nabla^2 + m^2\right) G_R(x) = \delta_D(x).$$

This is one of the key reasons why ideas like “relativistic wave-functions” involving single particle description run into serious conceptual difficulties.

1.2 Mission impossible?

It will be interesting to ask: can one find a representation for $G_R(x)$ which is similar in structure to that of $G_{NR}$ in eq. (1.4)? That is, can we define some kets $|x\rangle$, labeled by spatial coordinates and an operator $U_R(t)$, such that we can write

$$G_R(x) = \langle x_2 | U_R(t) | x_1 \rangle$$

(1.9)

At first sight, there are several obvious problems with a relation like eq. (1.9).

(i) The relativistic propagator $G_R$, unlike $G_{NR}$, does not satisfy eq. (1.2) and eq. (1.3) and hence it is never going to propagate a Schrodinger-like wave-function. This, in turn, means that the kets $|x\rangle$ cannot form an orthonormal set allowing a resolution of identity operator. In fact, the most crucial issue, in arriving at a relation of the form eq. (1.9), is in the definition of the ket $|x\rangle$ in quantum field theory. It is well known that defining a (particle) position operator and its eigenkets is conceptually dubious in quantum field theory because particles cannot be localized. That is, you cannot hope to define $|x\rangle$ as an
eigenket of a suitable position operator in QFT. They have to be defined by some indirect means and it is not clear whether such a definition will lead to a result like in eq. (1.9).

(ii) The non-relativistic propagator in eq. (1.4), defined without $\theta(t)$ — i.e., just as the matrix element — has the following property under time reversal: $G_{NR}(-t, x) = G_{NR}^*(t, x)$; time reversal leads to complex conjugation in NRQM. But the relativistic propagator in the left-hand-side of eq. (1.9) depends only on $t^2$ and hence is time-reversal invariant. This suggests that the evolution operator in eq. (1.9) cannot have the standard form, viz., exponential of a Hermitian operator which is linear in $t$. Therefore, we have no guarantee that the composition law $U(t_1)U(t_2) = U(t_1 + t_2)$ will hold.

(iii) The left hand of eq. (1.9) is Lorentz invariant. On the right hand side, space and time are clearly separated in the kets $|x_1\rangle, |x_2\rangle$ and in the operator $U(t)$. It is therefore not obvious how to find such a structure which will be Lorentz invariant.

The closest result to eq. (1.9) one comes across in the literature is the following: the Schwinger representation for the propagator, in eq. (1.5), can also be expressed as:

$$G(x) \propto \int_0^\infty ds \langle x_2 | e^{-isH} | x_1 \rangle; \quad H(p) \equiv -p^2 + m^2 - i\epsilon$$

The integrand looks similar to eq. (1.4) for $G_{NR}$ but, of course, this is not in the form of eq. (1.9) which I am seeking, because: (a) The states $|x_1\rangle, |x_2\rangle$ are now labeled with the four vectors $x^i$ rather than three vectors $x$ which I want in eq. (1.9). (b) The (super) Hamiltonian $H = -p^2 + m^2 - i\epsilon = \Box + m^2 - i\epsilon$ is quite different from what we would expect for the relativistic particle $H(p) = (p^2 + m^2)^{1/2}$. (c) Most crucially, we need to integrate over the Schwinger’s proper time $s$ in eq. (1.10) in order to get the propagator; in eq. (1.9) I want the propagator to be given directly as a matrix element.

I will show, in the next section, that — in spite of these issues — one can indeed define the right hand side of eq. (1.9) such that the equation holds! Indirectly (but precisely) defined kets $|x_1\rangle, |x_2\rangle$ along with an appropriate operator $U_R(t)$ is required for this job. In fact, the result goes deeper. It has been suggested in several previous works [2–5, 8–25] that when the quantum gravitational corrections are taken into account, the propagator $G_R(x)$ gets modified with $x^2$ in eq. (1.5) being replaced by $x^2 - L^2$ where $L^2 = O(1)L_P^2 = O(1)(G\hbar/c^3)$ is the square of the zero-point-length of the spacetime. It turns out that one can modify the operator $U_R(t)$ such that an equation like eq. (1.9) can actually lead to a propagator $U_{QG}(t)$ incorporating the zero-point-length. In fact, such a construction with quantum gravitational corrections actually explains some crucial features of the operator $U_R(t)$ which reproduces the standard propagator in QFT. In addition, $U_{QG}(t)$ gives us a glimpse of time evolution close to Planck scales.

2 Feynman propagator as a matrix element

My aim is to define the kets $|x\rangle$ and the operator $U_R(t)$ such that eq. (1.9) holds. I will first define the kets $|x\rangle$ and then define the operator $U_R(t)$.

Among the three issues (listed in the beginning of section 1.2 as (i), (ii) and (iii)) which one immediately notices with eq. (1.9), the most important one is how to define $|x\rangle$.
without ever introducing a position operator for a particle. To do this, we will start with
the eigenkets of the momentum operator and define $|x\rangle$ using them. This can be done as
follows.

A Hermitian momentum operator exists in QFT as the generator of spatial translations
in the one-particle sector of the standard Fock space. So, I will start by introducing a
complete set of orthonormal momentum eigenkets, $|p\rangle$ of this operator. We would then
like $\langle p'|p\rangle$ to be proportional to $\delta_D(p - p')$. This works in NRQM but the integration
over $d^3p\delta_D(p - p')$ is not Lorentz invariant. The relativistically invariant measure for
momentum integration is given by

$$d\Omega_p \equiv \frac{d^3p}{(2\pi)^3 \Omega_p}$$

with $\Omega_p = 2\omega_p$. This requires us
to define the states $|p\rangle$ with:

$$\langle p'|p\rangle = (2\pi)^3 \Omega_p \delta_D(p - p'); \quad d\Omega_p \equiv \frac{d^3p}{(2\pi)^3 \Omega_p}$$

(2.1)

so that $\langle p'|d\Omega_p \rangle = \delta_D(p' - p)d^3p$ and everything is Lorentz invariant. With this definition,
the resolution of unity and the consistency condition on the momentum eigenkets, read as:

$$1 \equiv \int d\Omega_{p'} \langle p'|p\rangle; \quad |p\rangle \equiv \int d\Omega_{p'} |p\rangle \langle p'|p\rangle$$

(2.2)

These relations can be taken care of by the choices in eq. (2.1). In the integration measure
as well as in the Dirac delta function, we have introduced a factor $\Omega_p$ which, of course,
cancels out in the right hand side of the second relation in eq. (2.2).

I now introduce the states $|x\rangle$ labeled by the spatial coordinates. In NRQM they could
be thought of as the eigenkets of the single-particle position operator $\hat{x}(0)$. But, of course,
in QFT, we do not have the natural notion of such a position operator; so I will not invoke
such a conceptually dubious procedure. But there is a simple alternative: we can define $|x\rangle$
by specifying its expansion in terms of the basis vectors $|p\rangle$. These expansion coefficients,
in turn, can be chosen using the fact that the momentum operator is the generator of
spatial translations: so we will define $|x\rangle$ by postulating the expansion coefficients for $|x\rangle$
in the $|p\rangle$ basis to be:

$$\langle p|x\rangle = e^{-ix\cdot p}$$

(2.3)

This is the same as the definition:

$$|x\rangle \equiv e^{-ix\cdot p}|0\rangle \equiv \int d\Omega_p e^{-ip\cdot x}|p\rangle; \quad \langle p|x\rangle = e^{-ix\cdot p}$$

(2.4)

We have set $\langle p|0\rangle = 1$ in the definition which, as it turns out, is the only consistent choice
for Lorentz invariance. This defines $|x\rangle$.

Note that the kets $|x\rangle$ etc. which we have defined, are not orthogonal. From the
definition of $|x\rangle$ in eq. (2.4), it follows that:

$$\langle y|x\rangle = \int d\Omega_p e^{-ip\cdot(x-y)} \neq \delta_D(x-y)$$

(2.5)

The evaluation of the integral leads to the standard result that $\langle y|x\rangle$ decreases exponenti-
ally for separations larger than the Compton wavelength $\lambda_c \equiv (h/mc)$. This is a direct
consequence of the fact that particles cannot be sharply localized in QFT.
Having defined the kets $|x\rangle$ we now turn to the form of the operator $U_R(t)$ which will reproduce $G_R$ through eq. (1.9). The normal choice would have been $\exp[-itH(p)]$ with $H(p) \equiv (p^2 + m^2)^{1/2}$; this choice, however, will not lead to a $G_R$ through eq. (1.9) because $G_R$ is an even function of $t$. To take care of it, I will define the operator $U_R(t)$ to be $\exp[-it|H(p)|]$. (This form can also be ‘guessed’ with a bit of reverse engineering from the structure of eq. (1.7).)

With these definitions of $|x\rangle$ and $U_R(t)$, I claim that the relativistic propagator is indeed given by the matrix element

$$G_R(x) = \langle x_2|U_R(t)|x_1 \rangle; \quad U_R(t) \equiv \exp[-i|t|H(p)] \tag{2.6}$$

The proof is straightforward. Inserting a complete set of momentum eigenstates within the matrix element in eq. (2.6), and using the last relation in eq. (2.4), we can evaluate the propagator explicitly to be:

$$G_R(x) = \langle x_b|e^{-i|t|H}|x_a \rangle = \int \frac{d^3p}{(2\pi)^3(2\omega_p)} \ e^{ipx-i\omega_p|t|} \tag{2.7}$$

This gives the correct result for the propagator in the representation in eq. (1.7). The Lorentz invariance of eq. (2.6) is assured because we know that the right-hand-side of eq. (2.7) is indeed Lorentz invariant, in spite of the appearance of $|t|$. I will now provide an alternate derivation of the same result leading directly to the Schwinger’s proper time representation in eq. (1.5). (This derivation has the advantage that it is easy to incorporate the zero-point-length, which I will do in the next section.) To do this, I start with the easily proved (operator) identity:

$$2H \int_0^\infty d\mu \ \exp\left(-i\mu^2H^2 - \frac{it^2}{4\mu^2}\right) = \left(\frac{\pi}{i}\right)^{1/2} \ e^{-it|H} \tag{2.8}$$

which allows us to write, for $H^2 = p^2 + m^2$,

$$\langle x_b|e^{-i|t|H}|x_a \rangle = \left(\frac{i}{\pi}\right)^{1/2} \int_0^\infty d\mu \ e^{-it^2/4\mu^2} \langle x_b|2H(p)e^{-i\mu^2H^2(p)}|x_a \rangle$$

$$= \left(\frac{i}{\pi}\right)^{1/2} \int_0^\infty d\mu \ e^{-it^2/4\mu^2} \ e^{-i\mu^2m^2} \langle x_b|2H(p)e^{-i\mu^2p^2}|x_a \rangle \tag{2.9}$$

The matrix element we need can now be evaluated by introducing a complete basis of momentum eigenkets $|p\rangle$ with integration measure $d\Omega_p = d^3p/[(2\pi)^32\omega_p]$ for the momentum integration. This gives, with $x \equiv x_b - x_a$ the result:

$$\langle x_b|2H(p)e^{-i\mu^2p^2}|x_a \rangle = \int \frac{d^3p}{(2\pi)^3} \ e^{ipx} [2\omega_p e^{-i\mu^2p^2}] = \left(\frac{\pi}{i\mu^2}\right)^{3/2} \frac{1}{8\pi^3} \exp\left(\frac{ix^2}{4\mu^2}\right) \tag{2.10}$$

The $2\omega_p$ arising from $2H$ in the left hand side of eq. (2.8) cancels the $(1/2\omega_p)$ in the measure of integration in the momentum space, giving a relatively simple result. Substituting
eq. (2.10) into eq. (2.9) we leads to the final result, with $x^2 = x^α x_α = t^2 - x^2$

$$\langle x_2| e^{-iHt} | x_1 \rangle = \left( \frac{i}{\pi} \right)^{1/2} \frac{(\pi)^{3/2}}{8\pi^2} \int_0^{\infty} \frac{ds}{s^2} \exp \left( -\frac{iπ^2 s}{4s} - im^2 s \right)$$

$$= \frac{1}{i} \frac{1}{16\pi^2} \int_0^{\infty} \frac{ds}{s^2} \exp \left( -i \left( \frac{x^2}{4s} + m^2 s \right) \right)$$  (2.12)

This is, of course, the Schwinger representation of the propagator in eq. (1.5); it is manifestly Lorentz invariant.

The result in eq. (2.6) is rather remarkable for several reasons. To begin with, the left hand side $G_R(x_2, x_1)$ is Lorentz invariant while in the right hand side, the matrix element, $\langle x_2| U_R(t) | x_1 \rangle$ separates space and time in a very concrete manner. Second, we do not have any simple physical interpretation for the kets $|x\rangle$ in QFT. Their definition, through their expansion in the momentum basis, is rigorous and unambiguous but it is not clear what they physically mean; this is again because we do not have a notion of position operator. (In spite of several attempts in the literature, it has not been possible to define a conceptually sensible single particle position operator in QFT — and there are excellent reasons for this failure; see e.g., [6].) Third, the occurrence of $|t\rangle$ in the evolution operator (and the propagator) is vital for the consistent interpretation of the theory with particles and antiparticles. (I will have more to say about this later on.) So the matrix element does not describe a single-particle propagation but actually encodes the sophisticated interplay of particle and antiparticle propagation in a rather succinct manner. Finally, I will show, — in the next section — that a similar result holds even when we incorporate quantum gravitational corrections to the propagator through a zero-point-length in spacetime.

I will conclude this section by noting that there is an alternative integral representation of the evolution operator, using the function

$$f(\nu, z) \equiv \int_{-\infty}^{\infty} \frac{ds}{iπ} \left[ z^2 - s^2 - i\epsilon \right] e^{-iνs}, \quad (ν > 0)$$  (2.13)

defined in the entire complex plane with $z = x + iy$. This function is useful for defining the analytic continuation of $|t\rangle$ when one proceeds from the Lorentzian to Euclidean sector with $t_E = it$. It is easy to verify that: $f(\nu, z = x) = e^{-iν|x|}$ for $ν > 0$ and $x$ along the real line. We also have $f(ν, z = iy) = e^{-\nu|y|}$ for $ν > 0$ and $y$ real which gives rigorous meaning to treating $e^{-iν|t_E|}$ as the Euclidean extension of $e^{-iν|t|}$. (We will need this result later.) This leads to an integral representation, for any positive definite Hamiltonian operator $H$:

$$U_R(t) = f[H, t] = e^{-iH|t|} = \int_{-\infty}^{\infty} \frac{ds}{iπ} \left[ \frac{s}{t^2 - s^2 - i\epsilon} \right] e^{-iHs}$$  (2.14)

which expresses the operator $e^{-iH|t|}$ in terms of the operator $e^{-iHs}$. This, in turn, provides a curious interpretation of the propagator. Our result in eq. (2.14) allows us to write the propagator as:

$$G_R(t, x_2, x_1) = \langle x_2| e^{-iH|t|} | x_1 \rangle = \int_{-\infty}^{\infty} dτ \ A(t; τ) \langle x_2| e^{-iHτ} | x_1 \rangle$$  (2.15)
with\(^4\)

\[
A(t;\tau) \equiv \frac{1}{(i\pi)} \left[ \frac{\tau}{t^2 - \tau^2 - i\epsilon} \right] \tag{2.16}
\]

In the integrand in the right hand side of eq. (2.15), the factor \(\langle x_2|e^{-iH\tau}|x_1\rangle\) gives the amplitude for propagation \(x_1\) to \(x_2\) in a (virtual) time interval of duration \(\tau\); this is multiplied by the amplitude \(A(t;\tau)\) for a virtual time interval \(\tau\) to correspond to a physical time interval \(t\). On integrating this expression over all values of virtual time interval \(\tau\), we get the amplitude for propagation \(x_1\) to \(x_2\) in a physical time interval \(t\). All the physics of particle-antiparticle propagation encoded in the \(\tau\) factor of \(\exp(-iH\tau)\) is eliminated by introducing a virtual time interval and the amplitude \(A(t;\tau)\). Instead of summing over virtual paths which go both forward and backward in time, we are summing over paths connecting the same \(x_1\) and \(x_2\) but with different time intervals, ranging over the whole real line.\(^5\)

3 Propagator with quantum gravity corrections

There exists a well-defined regime in which one can meaningfully talk about QG corrections to the standard QFT propagator. I will first describe this context and then introduce the QG-corrected propagator. I will then show that the QG-corrected propagator can also be expressed as a matrix element, in the form of eq. (1.9), with the same kets \(|x\rangle\) but with a modified evolution operator \(U_{\text{QG}}(t)\). This, in turn, gives us some insight into time evolution close to Planck scales.

3.1 Mesoscopic scales and the zero-point-length

I will consider a region of curved spacetime in which the curvature length\(^6\) scale \(L_{\text{curv}}\) is much larger than Planck length: i.e., \(L_{\text{curv}} \gg L_P\). (If this condition is not satisfied we need the full machinery of QG which we do not have.) In that case, there exists a well-defined regime in which one can usefully introduce QG corrections to the standard QFT propagator. To do this, it is useful to introduce the notion of mesoscopic regime, which interpolates between the macroscopic regime (where one can use the standard formalism of QFT in CST) and the microscopic regime, very close to and even smaller than the Planck scale (which requires a full quantum gravitational description). This mesoscopic regime is close, but not too close, to the Planck scale so that we can still introduce some kind of effective geometric description, while incorporating quantum gravitational effects to the leading order.

\(^4\)This expression is superficially similar to that in eq. (1.10) but, of course, is distinct from it. The kets in eq. (2.15) are labeled by spatial coordinates, \(x\), while the kets in eq. (1.10) are labeled by the spacetime coordinates \(x^i\). The Hamiltonian in eq. (2.15) is just \(H = (p^2 + m^2)^{1/2}\) while the (super) Hamiltonian in eq. (1.10) is \(H = -p^2 + m^2\); and we do not have an amplitude like \(A(t;\tau)\) appearing in eq. (1.10).

\(^5\)I stress that we are doing standard QFT here. In fact, eq. (2.15) can be thought of as an integral convolution which converts the Wightman function \(\langle x_2|e^{-iH\tau}|x_1\rangle\) to Feynman propagator \(\langle x_2|e^{-iHt}|x_1\rangle = \langle 0|T[\phi(t,x_2)\phi(0,x_1)]|0\rangle\).

\(^6\)At any given event \(\mathcal{P}\), the \(L_{\text{curv}}\) could be defined in terms of typical curvature components; e.g., we can define \(L_{\text{curv}}^2 = \sqrt{R^{abcd}R_{abcd}}\) evaluated at \(\mathcal{P}\).
What happens to the QFT propagator at mesoscopic scales? The classical geometrical description will be modified close to Planck scales in a manner which is at present unknown. However, we can capture the most important effects of quantum gravity by introducing a zero-point-length to the spacetime [8–25]. This is based on the idea that the dominant effect of quantum gravity at mesoscopic scales can be described by assuming that the path length $\sigma^2(x_2, x_1)$ in the Euclidean sector\(^7\) has to be replaced by $\sigma^2(x_2, x_1) \to \sigma^2(x_2, x_1) + L^2$ where $L^2$ is of the order of Planck area $L^2_P \equiv (G\hbar/c^3)$.

It is possible to work out how this modification translates to the form of the propagator. One can show that [8, 9] the Euclidean propagator is now modified to:

$$G_{QG}(x, y; m) = \int_0^\infty \! ds \ e^{-m^2 s - L^2/4s} K_{\text{std}}(s; x, y)$$  \hspace{1cm} (3.1)

where $K_{\text{std}}$ is the zero-mass, Schwinger (heat) kernel given by $K_{\text{std}}(x, y; s) \equiv \langle x | e^{s\Box_y} | y \rangle$. The $\Box_y$ is the Laplacian in the background space(time). Recall that the leading order behaviour of the heat kernel is given by $K_{\text{std}} \sim s^{-2} \exp[-\sigma^2(x, y)/4s]$ where $\sigma^2$ is the geodesic distance between the two events; therefore, the modification in eq. (3.1) amounts to the replacement $\sigma^2 \to \sigma^2 + L^2$ to the leading order, which makes perfect sense.

Analytic continuation will give the propagator with zero-point-length in the Lorentzian sector. In the flat spacetime, we now get the propagator, incorporating the zero-point-length of the spacetime to be:

$$G_{QG}(x) = \frac{1}{i\pi} \frac{1}{16\pi^2} \int_0^\infty \! \frac{ds}{s^2} \ e^{-i\left(\frac{x^2 - L^2}{4s} + m^2 s\right)}$$  \hspace{1cm} (3.2)

which is manifestly Lorentz invariant. (To ensure convergence of the $s$ integral at the two limits, we must interpret $x^2$ as $x^2 - i\delta$ and $m^2$ as $m^2 - i\epsilon$. This, of course, was required even in the standard QFT propagator (with $L = 0$) given by the Schwinger representation in eq. (1.5). No new regulator is needed due to the addition of zero-point-length.)

Before proceeding further, let me stress some aspects of this approach — which incorporates zero-point-length into the propagator — for the sake of conceptual completeness. This will be helpful to readers who are not sufficiently familiar with previous work on this approach.

- Rigorously speaking, To study the effects of quantum gravity at mesoscopic scales we need to start from a full theory of quantum gravity at microscopic scales (for both spacetime geometry and matter fields) and work out a suitable coarse-grained approximation, involving an effective geometry, at mesoscopic scales. However, since we do not at present possess the complete theory of QG or the description of matter fields at the microscopic scales, one needs to make some working hypothesis to proceed further. The idea of introducing the zero-point-length by the ansatz $\sigma^2(x_2, x_1) \to \sigma^2(x_2, x_1) + L^2$ should be thought of as such a working hypothesis which is postulated to make further progress. This idea has been introduced and explored extensively in

\(^7\)The zero-point-length is added to the spatial distance in the Lorentzian sector. With our signature, in flat spacetime, this involves the replacement of $x^2 \equiv (t^2 - x^2)$ by $x^2 - L^2 = (t^2 - x^2 - L^2)$ etc.
the past two decades or so in the literature [8–25]. In this paper, I will be exploring some further consequences of this approach.

It is, however, possible to view this construction (and its implementation in the context of the propagator) in the backdrop of candidate models of quantum gravity. For example, it can be obtained from the string theory [26] in a specific approximation. Three ingredients of string theory viz., zero-point-length, extra-dimensions and the string T-duality play a role in this construction, in terms of a Kaluza-Klein theory that interpolates between (high-energy) string theory and (low-energy) quantum field theory. The zero-point-length in four dimensions arises as a residue of the length scale of compact extra-dimensions. From a low energy perspective, the short distance infinities are cut off by a minimal length. One then obtains [26] precisely the propagator $G_{QG}$ constructed earlier by the replacement $\sigma^2(x_2, x_1) \rightarrow \sigma^2(x_2, x_1) + L^2$.

While this is possible, I emphasize that I do not require any string theory input in the discussion here, once the replacement $\sigma^2(x_2, x_1) \rightarrow \sigma^2(x_2, x_1) + L^2$ is accepted as a working hypothesis.

- By working directly with the propagator, we bypass several nuances of standard QFT which may all require some unknown form of revision at mesoscopic scales. In this approach we exploit the fact that both the dynamics and the symmetries of a free quantum field, propagating in a curved geometry, are completely encoded in the Feynman propagator. So, if we have an ansatz to incorporate the QG effects in the propagator, we obtain a direct handle on both the dynamics and the symmetries of the theory at mesoscopic scales. This is an efficient procedure which encourages us to work directly with the propagator containing QG corrections, without worrying about the (unknown) modifications to the standard formalism of QFT at mesoscopic scales.

- One important consequence of working directly with the propagator is the following: the diffeomorphism invariance in a curved geometry and — as a special case — Lorentz symmetry in flat spacetime is preserved in this approach. The prescription $\sigma^2(x_2, x_1) \rightarrow \sigma^2(x_2, x_1) + L^2$ is generally covariant when $L$ is treated as a constant scalar number. In flat spacetime, this modification will replace $(x_2 - x_1)^2$ by $(x_2 - x_1)^2 + L^2$ which is clearly Lorentz invariant. (The mere introduction of a constant, scalar, length scale into the propagator will not violate Lorentz invariance, as should be obvious from the fact that the propagator for the massive scalar does depend on the length scale $m^{-1}$ and is still perfectly Lorentz invariant. The appearance of this length scale $L$ in the propagator has the same conceptual status as the appearance of, for example, the Compton wavelength $m^{-1}$ in the propagator.) It is not obvious how such symmetries can be preserved at the mesoscopic scales when we modify the formalism of QFT, with the usual canonical quantization, Fock basis etc. Using the propagator to encode the dynamics as well as the symmetries helps us to bypass such non-trivial issues; this is one reason why this formalism was powerful enough to do concrete computations in a wide variety of contexts in the past literature. The
results of such computations (see e.g., the extensive set of computations refs. [24, 25]) demonstrate the general covariance and Lorentz invariance explicitly.\(^8\)

- The propagator has a completely geometric interpretation in terms of a world line path integral — see eq. (A.3) of appendix A — which does not use the formalism of fields, canonical quantisation etc. (This is outlined in appendix A for the sake of those who always think of a propagator as a two-point function of a field; you can define the propagator without introducing the notion of a field or its canonical quantisation.) Further, the action for a relativistic particle possesses a simple — but not well-appreciated — feature. The relativistic particle action is obviously expected to be a functional of the form \(A[x^a(\tau); x_1, x_2]\); that is, it is a functional of the world-line \(x^a(\tau)\) and a function of \(x_2\) and \(x_1\). But, it can be expressed purely as a function \(A = A(\ell)\) of the length of the path \(\ell[x^a(\tau); x_2, x_1]\), which carries the functional dependence on the world-line \(x^a(\tau)\). This geometrical structure of action for the relativistic particle is a very special; in contrast, the standard action for the non-relativistic particle cannot be expressed purely as a function of the length of the path. It is this feature which allows us to translate the modification of path lengths in spacetime (by the addition of the zero-point-length) to the modification of the relativistic action and thus of the propagator. This, in turn, allows us to preserve all the relevant symmetries of the theory and directly compute the corrections to the propagator at mesoscopic scale.

After this aside, let me now return to the main topic. Once the Schwinger representation of the propagator is known, we can immediately write down the expression corresponding to eq. (1.7). One can, of course, obtain it by Fourier transforming eq. (3.2) with respect to the spatial coordinates \(x\). More simply, one can reason out as follows: the equivalence of eq. (1.7) with eq. (1.5) holds for any real parameter \(t\). Therefore, replacing \(|t|\) by \((t^2 - L^2)^{1/2}\) in eq. (1.7) is equivalent to replacing \(x^2 \equiv t^2 - x^2\) by \(x^2 - L^2\) in eq. (1.5).

But this is precisely the introduction of zero-point-length which converts \(G_R(x)\) to the quantum corrected propagator \(G_{QG}(x)\). Therefore, we get the result:

\[
G_{QG}(x) = \int \frac{d^3p}{(2\pi)^3(2\omega_p)} e^{i p \cdot x - i\omega_p \sqrt{t^2 - L^2}}
\]  

which just involves replacing \(|t|\) by \((t^2 - L^2)^{1/2}\) in eq. (1.7). This expression is rather remarkable and we will exploit it in the next section.\(^9\) These expressions eq. (3.2), eq. (3.3) describe the QG corrections to the propagator at mesoscopic scales.

To avoid possible confusion, let me mention the following (algebraic) fact: we all know that the measure \(d^3p/(2\omega_p)\) is Lorentz invariant; so is the standard combination \((\omega_p t - p \cdot x)\). It way appear, at first sight, rather surprising that the expression in the right hand side of eq. (3.3) is also Lorentz invariant — which follows from the fact that the left hand side,

\(^8\)Some other prescriptions in the literature for introducing a ‘minimal length’ do create problems for Lorentz invariance but our prescription does not; it is generally covariant.

\(^9\)The mesoscopic scale description is valid only when \(t^2 \gtrsim L^2\); in this range the phase remains real in eq. (3.3). We will say more about this feature later on.
which depends only on \(x^2\) is Lorentz invariant — in spite of \(t\) being replaced by \((t^2 - L^2)^{1/2}\).

To understand this result, consider an arbitrary scalar function \(F\) of the Lorentz invariant variable \(p^2 - m^2\), say: \(F(p^2 - m^2) = F(\nu^2 - \omega_p^2)\) and its four-dimensional Fourier transform, written as:

\[
I(x^2) \equiv \int d^4p F(p^2)e^{-ipx} = \int d^3p \, e^{ip\cdot x} \int_{-\infty}^{\infty} d\nu \, F(\nu^2 - \omega_p^2)e^{-i\nu t} \tag{3.4}
\]

The \(\nu\) integration will lead to a function, say, \(Q(t^2, \omega_p^2)/(2\omega_p)\) so that:

\[
I(x^2) = \int \frac{d^3p}{(2\omega_p)} R(t^2, \omega_p^2)e^{ip\cdot x} \tag{3.5}
\]

with

\[
R(t^2, \omega_p^2)/(2\omega_p) = \int_{-\infty}^{\infty} d\nu \, F(\nu^2 - \omega_p^2)e^{-i\nu t}; \quad F(\nu^2 - \omega_p^2) = \int_{-\infty}^{\infty} dt \, \frac{R(t^2, \omega_p^2)}{(2\omega_p)} e^{i\nu t} \tag{3.6}
\]

Clearly, the expression in the right hand side of eq. (3.5) is Lorentz invariant in spite of appearance. The expression in eq. (3.3) has exactly this form with \(R = (2\pi)^{-3}e^{-i\omega_p\sqrt{t^2 - L^2}}\).

Its Fourier transform, \(F(\nu^2 - \omega_p^2)\) can be expressed in terms of Bessel functions and its explicit form is given in the appendix. A large class of integrals of the form \(I(x^2)\) in eq. (3.5) can be Lorentz invariant without being \textit{manifestly} Lorentz invariant.

### 3.2 Propagator with zero-point-length as a matrix element

The quantum corrected propagator, obtained by introducing a zero-point-length, is a rather strange beast. While it can be obtained from a path integral (see [8, 9] and appendix A) and can be used to compute explicitly the QG corrections to several QFT/QED phenomena (see e.g., [24, 25]), it \textit{cannot} be expressed as a time ordered correlator of a local quantum field. In the context of the current work, the question arises as to whether this propagator can also be expressed as a matrix element of some time evolution operator \(U_{\text{QG}}(t)\). If we could do that, it will throw some light into the concept of time evolution at mesoscopic scales close to Planck length.

I will now show that not only this can be done but also both the derivation and the result are extremely simple. I will show that all we need to do is to replace the time evolution operator \(U_R = \exp(-iH(t_2 - t_1))\) by

\[
U_{\text{QG}}(t) = \exp(-iH\sqrt{t^2 - L^2}); \quad t = t_2 - t_1 \tag{3.7}
\]

to get the correct result. I will first derive the result and discuss the implications afterwards.

A simple way to arrive at the correct answer is as follows: in eq. (2.7) the real variable \(|t|\) goes for a ride on both sides of the equation. So if you replace \(|t|\) by any other real variable, the equation will continue to hold. I will replace \(|t|\) by \((t^2 - L^2)^{1/2}\) with the understanding that the positive square root is taken. This will lead to the result

\[
\langle x_0 | e^{-iH\sqrt{t^2 - L^2}} | x_\alpha \rangle = \int \frac{d^3p}{(2\pi)^3(2\omega_p)} \, e^{ip\cdot x - i\omega_p\sqrt{t^2 - L^2}} \tag{3.8}
\]
But the right hand side of eq. (3.8) is precisely the right hand side of eq. (3.3). Therefore we immediately get the result:

$$G_{QG}(x) = \langle x_a | e^{-iH\sqrt{t^2-L^2}} | x_a \rangle$$

(3.9)

One can also obtain the same result from modifying the derivation leading to eq. (2.12). In the operator identity in eq. (2.8) the parameter $t$ goes for a ride on both sides; that is, the identity will hold with $t$ replaced by any other real quantity. I will replace $t^2$ in the left hand side by $(t^2 - L^2)$ thereby getting the result:

$$2H \int_0^\infty d\mu \exp \left(-i\mu^2H^2 - \frac{i(t^2 - L^2)}{4\mu^2} \right) = \left( \frac{\pi}{t} \right)^{1/2} e^{-iH\sqrt{t^2-L^2}}$$

(3.10)

That is all we need; it is obvious that the entire derivation proceeds exactly as before and leads to — in place of eq. (2.12) — the modified result:

$$\langle x_b | e^{-iH\sqrt{t^2-L^2}} | x_a \rangle = \frac{1}{i} \frac{1}{16\pi^2} \int_0^\infty \frac{ds}{s^2} \exp \left(-i \left( \frac{x^2 - L^2}{4s} + m^2 s \right) \right)$$

(3.11)

The right hand side, of course, is the QG corrected propagator so that we can now write:

$$G_{QG} = \langle x_b | e^{-iH\sqrt{t^2-L^2}} | x_a \rangle$$

(3.12)

Since we expect the mesoscopic scale description to be valid only for $t = t_2 - t_1 > L$, the phase is real and the evolution operator is unitary for Hermitian $H$. I will now make a brief digression to show how these results can be generalized to a wider class of spacetimes and then discuss several implications of these results in section 5.

4 Aside: generalization to ultrastatic spacetime

The results in the previous two sections — related to the representation of $G_R$ and $G_{QG}$ as matrix elements of the evolution operators — remain valid in a wider class of curved spacetime (sometimes called ultrastatic) with the line element:

$$ds^2 = dt^2 + h_{\alpha\beta}(x) \ dx^\alpha \ dx^\beta$$

(4.1)

(Note that, with our signature convention, $h_{\alpha\beta}$ will be a negative definite metric.) The static nature of the spacetime ensures that both $G_R(t, x_2, x_1)$ and $G_{QG}(t, x_2, x_1)$ depends on time only through the difference $t \equiv (t_2 - t_1)$. I will first show that, in such a curved background, $G_{QG}$ is obtained by replacing $t$ by $\sqrt{t^2 - L^2}$ in $G_R$. I will obtain the expression for $G_{QG}$ directly which will reveal this structure.

We start with the prescription for the propagator incorporating the zero-point-length in an arbitrary curved spacetime:

$$G_{QG}(x_2, x_1) = \int_0^\infty ds \ e^{-im^2 s + (iL^2/4s)} \langle x_2 | e^{-i\Box} | x_1 \rangle$$

(4.2)
where the four-dimensional Laplacian \( \Box \) separates into

\[
\Box = \frac{1}{\sqrt{-g}} \partial_a \left( \sqrt{-g} g^{ab} \partial_b \right) = \frac{\partial^2}{\partial t^2} + \frac{1}{\sqrt{h}} \partial_\alpha \left( \sqrt{h} h^{\alpha\beta} \partial_\beta \right) = \frac{\partial^2}{\partial t^2} + \nabla^2_h
\]  

(4.3)

This guarantees that we can also separate the kets \(|x\rangle\) into the direct product \(|t\rangle|\mathbf{x}\rangle\) such that

\[
e^{-is\Box}|x_1\rangle = e^{-is\partial_t^2}|t_1\rangle e^{-is\nabla^2_h}|\mathbf{x}_1\rangle
\]  

(4.4)

We now introduce the eigenstates \(|\omega\rangle\) of the one-dimensional operator \(\partial_t^2\) and expand the kets \(|t_1\rangle\) etc. in the form

\[
|t_1\rangle = \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} e^{i\omega t_1}|\omega\rangle; \quad \langle \omega|t\rangle = e^{i\omega t}; \quad \langle t|\omega\rangle = e^{-i\omega t}
\]  

(4.5)

and evaluate the time dependence of the matrix element as:

\[
\langle x_2|e^{-is\Box}|x_1\rangle = \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} e^{i\omega t_2} e^{-i\omega t_1} \langle x_2|e^{-i\nabla^2_h}|x_1\rangle = \left( \frac{i}{4\pi s} \right)^{1/2} e^{-i(\omega t_2/4s)} \langle x_2|e^{-i\nabla^2_h}|x_1\rangle
\]  

(4.6)

Substituting this into eq. (4.2), we immediately find that \(G_{QG}\) depends on \(t\) through the combination \((t^2 - L^2)\). Since \(L = 0\) reduces \(G_{QG}\) to \(G_R\), we get the result we are seeking, viz.,

\[
G_{QG}(t, x_2, x_1) = G_R \left( \sqrt{t^2 - L^2}, x_2, x_1 \right)
\]  

(4.7)

This is, of course, completely analogous to what we found earlier in the special case of the flat spacetime.

I will next define a suitable set of kets \(|\mathbf{x}\rangle\), labeled by the spatial coordinates, and prove that \(G_R\) itself can be expressed as the matrix element

\[
G_R(t, x_2, x_1) = \langle x_2|e^{-i(t\mathbf{p}^2/4s)}|x_1\rangle
\]  

(4.8)

where \(H^2 = \mathbf{p}^2 + m^2\) with \(\mathbf{p}^2\) evaluated using (negative of) the spatial metric \(-h^{\alpha\beta}\). We can again introduce the kets \(|\mathbf{x}\rangle\) exactly as before, by using generalized mode functions in place of \(e^{i\mathbf{p}\cdot\mathbf{x}}\) which we used earlier. Let the eigenkets of the operator \(H^2\) be \(|\omega, \mu\rangle\) with

\[
H^2|\omega, \mu\rangle = \omega^2|\omega, \mu\rangle
\]  

(4.9)

where \(\mu\) collectively denotes all other parameters of the eigenket. (For example, in flat spacetime, we earlier labeled the eigenkets of \(H\) by the three components of the momentum \(|\mathbf{p}\rangle\) with \(\omega^2 = m^2 + \mathbf{p}^2\). Instead, we could have traded off \(p_x\) for \(\omega\) and labeled the eigenkets by \(|\omega, p_y, p_z\rangle\) so that \(\mu = (p_y, p_z)\).) Further, we can construct the propagator — as a solution to \((\Box + m^2)G_R = \delta_D\) — in terms of a complete set of orthonormal mode functions \(F(x)\) which satisfy the homogeneous equation \((\Box + m^2)F = 0\). In the ultrastatic spacetime, we can choose the mode functions to be \(F = f_{\omega\mu}(\mathbf{x}) e^{\pm i\omega t}\), separating out the time dependence.

We will choose \(f_{\omega\mu}\) to be real, which can always be done, for convenience. The relativistic propagator which satisfies the equation \((\Box + m^2)G_R = \delta_D\) can now be constructed in terms of the mode functions as:

\[
G_R(x) = \sum_{\omega, \mu} e^{-i\omega t} f_{\omega\mu}(\mathbf{x}_2) f_{\omega\mu}(\mathbf{x}_1)
\]  

(4.10)
We will now define the kets $|x\rangle$ by the expansion

$$|x\rangle = \sum_{\omega, \mu} \omega, \mu |\omega, \mu\rangle ; \quad \langle x|\omega, \mu\rangle = f_{\omega, \mu}(x); \quad \langle x|\omega, \mu\rangle = f_{\omega, \mu}(x) \quad (4.11)$$

It follows that

$$\langle x_2|e^{-iH|t} |x_1\rangle = \sum_{\omega, \mu} f_{\omega, \mu}(x_2) f_{\omega, \mu}(x_1) e^{-i\omega|t|} \quad (4.12)$$

Comparing with eq. (4.10), we find that the right hand side is just $G_R$. This immediately leads to the result quoted in eq. (4.8). Combined with eq. (4.7), we find that the propagator incorporating the zero-point-length can again be expressed in the form

$$G_QG(t, x_2, x_1) = \langle x_2|e^{-iH\sqrt{t^2-L^2}} |x_1\rangle \quad (4.13)$$

in all ultrastatic spacetime. The results in the previous sections can be thought of as special cases when the spatial metric represents flat spacetime.

5 Discussion

5.1 Some consequences of the result

The mesoscopic scale is defined to be close to but somewhat larger than the Planck scale. This necessarily implies that the idea of a quantum corrected propagator is conceptually meaningful only if $t^2 > L_P^2$ (and $|x|^2 > L_P^2$). So, strictly speaking, our considerations in the last section is valid only when $(t^2 - L_P^2) > 0$. In that case, the phase of the modified evolution operator, $\exp(-iH\sqrt{t^2-L_P^2})$ remains real and meaningful. It implies that we can talk about a unitary time evolution only when $t_2 - t_1 > L_P$, which makes physical sense. The description in terms of a smooth geometry and a QG corrected propagator is conceptually dubious when the time interval $t_2 - t_1$ is sub-Planckian.

There are some interesting aspects of this (modified) time evolution operator which is worth mentioning. We saw earlier that, in the standard QFT, the evolution operator is given by

$$e^{-iH|t|} = \theta(t)e^{-iHt} + \theta(-t)e^{iHt}; \quad t = t_2 - t_1 \quad (5.1)$$

This shows that positive frequency modes are propagated forward in time while negative frequency modes are propagated backwards in time. This is also closely related to the notion of antiparticles and the propagator being a time-ordered product. All these becomes apparent (see e.g., [1]) when we look at a complex scalar field for which the antiparticle is distinct from the particle. If we write the complex scalar field as the sum $\phi(x) \equiv A(x) + B^\dagger(x)$ with

$$A(x) \equiv \int d\Omega_p A_p e^{-ipx}; \quad B(x) \equiv \int d\Omega_p B_p e^{-ipx} \quad (5.2)$$

where $A_p$ and $B_p$ are the standard annihilation operators, then the propagator is given by:

$$\langle x_2|e^{-iH|t|} |x_1\rangle = \theta(t)(0|A(x_2)A^\dagger(x_1)|0) + \theta(-t)(0|B(x_1)B^\dagger(x_2)|0) \quad (5.3)$$
which clearly shows that the $|t|$ is vital to ensure proper propagation of particles and antiparticles.

The following (algebraic) fact is equally important. The solutions of the Klein-Gordan equation will involve mode functions with time evolution $f \sim e^{\pm i\omega_p t}$ without any $|t|$. The bilinear forms of mode functions used in constructing the propagator (which only depends on $(t_2 - t_1)$) can only involve the products like $f(t_1)f^*(t_2)$ etc. will go as $e^{\pm i\omega_p(t_2 - t_1)}$, again without $|t|$. To get the $|t|$ in the evolution operator and the propagator — which is vital for describing the antiparticles — it is necessary to use the $\theta$ functions as in eq. (5.1). This, in turn, requires the time-ordered correlator, which leads to the right hand side in eq. (5.3) involving two field operators. So the $|t|$, time-ordered correlator and the existence of antiparticles are closely related.

It is therefore intriguing to see how this $|t|$ arises from the more exact description containing the zero-point-length. We now have $\sqrt{t^2 - L^2}$ (as argued earlier, we will now assume $t^2 > L^2$) instead of $|t|$; when we take the limit of $L \to 0$ we get the expression $\sqrt{t^2}$ with two possible signs for the square root. It makes physical sense to define $\sqrt{t^2}$ as an even function of $t$ by taking:

$$\sqrt{t^2} = \theta(t)t + \theta(-t)(-t) = |t| \quad (5.4)$$

This will lead to the correct limiting behaviour and standard QFT when $L \to 0$, as it should. For $t^2 \gg L^2$ we get the expansion:

$$e^{-iH\sqrt{t^2 - L^2}} = e^{-iH|t|} \left[ 1 + \frac{iHL^2}{2|t|} \right] = \theta(t)e^{-iHt} \left[ 1 + \frac{iHL^2}{2t} \right] + \theta(-t)e^{iHt} \left[ 1 - \frac{iHL^2}{2t} \right] \quad (5.5)$$

It is not easy to interpret this cleanly in terms of particle -antiparticle propagation. The result suggests that even the basic notion of particles and antiparticles might require revision close to Planck scales. This fact is also apparent from the fact the QG corrected propagator cannot be expressed as the time-ordered correlator of an underlying quantum field operator. The standard QFT description, when particles emerge as excitations of an underlying operator fails near Planck scales, even though the propagator itself remains well-defined.

### 5.2 Speculations about trans-Planckian scales

The discussion so far is mathematically well-defined and arises as a direct consequence of our ansatz $\sigma^2 \to \sigma^2 + L^2$ to capture mesoscopic scale physics. Let me now consider the form of the evolution operator for $t^2 = (t_2 - t_1)^2 < L^2$, i.e., at sub-Planckian scales. Conceptually, we cannot use our ideas of mesoscopic scales — and a QG corrected propagator in an effective geometry — at sub-Planckian scales. It is however tempting to speculate as to what the result could mean when $t^2 < L_p^2$. Very often in physics, mathematical structures allow extrapolation of concepts beyond their originally defined domain of validity thereby leading to fresh insights. With this possibility in mind, I will now speculate as to what happens to the above results when $t^2 < L_p^2$. 

[Note: The page number in the image suggests that this is page 16, but the text is not continuous from page 15, indicating that the content is incomplete or fragmented.]
Let us begin with Schwinger representation for the QG corrected propagator given in eq. (3.2) with the $\epsilon, i\delta$ factors explicitly displayed:

$$
G_{QG}(x) = \frac{1}{i} \frac{1}{16\pi^2} \int_{0}^{\infty} \frac{ds}{s^2} \exp\left(-i\left(\frac{x^2 - L^2 - i\delta}{4s} + (m^2 - i\epsilon)s\right)\right)
$$

(5.6)

This expression can be integrated exactly as in standard QFT (in the limit of $L = 0$) to give the result in eq. (1.8) with $x^2$ replaced $x^2 - L^2$ with $\epsilon\delta$ prescriptions implicitly understood. This means that the QG corrected propagator, expressed in Schwinger representation in eq. (5.6), is well defined for all values of $t^2 - |x|^2 - L^2$. This is obvious from the fact that the integral in eq. (5.6) converges for all values of $t^2 - |x|^2 - L^2$ because of our $\epsilon\delta$ prescriptions. So, while the expression is conceptually meaningful only when $t^2 \geq L^2$ and $|x|^2 \geq L^2$, it is algebraically meaningful even at sub-Planckian scales; the addition of a zero-point-length merely shifts the location of light cone (where $x^2 = 0$) in the spacetime.

Since the Schwinger representation remains well defined for the QG corrected propagator even at sub-Planckian scales, it is obvious that we should be able to define other representations for the propagator as well, for sub-Planckian scales, with suitable choice of square-root conventions etc. Let us, for example, consider the equivalence between Schwinger representation in eq. (5.6) and the one in eq. (3.3) which has a square-root, $\sqrt{t^2 - L^2}$ in the phase. To check the equivalence of eq. (5.6) and eq. (3.3) explicitly, we will take the spatial Fourier transform of eq. (5.6). This requires the computation

$$
\int G_{QG}(x_2; x_1)e^{-ip \cdot x} d^3x = -\frac{i}{16\pi^2} \int_{0}^{\infty} \frac{ds}{s^2} e^{-im^2s-i[(t^2-L^2)/4s]} \int d^3x \ e^{i|x|^2/4s-ip \cdot x}
$$

(5.7)

Evaluating the Gaussian integrals over $x$, and writing $s = \rho^2$, we find that:

$$
\int G_{QG}(x_2; x_1)e^{-ip \cdot x} d^3x = \left(\frac{i}{\pi}\right)^{1/2} \int_{0}^{\infty} d\rho \exp\left(-i\omega^2 p^2 - \frac{i(t^2 - L^2)}{4\rho^2}\right)
$$

(5.8)

Recall, from standard QFT, that $\omega^2_p$ is actually $\omega^2 - i\epsilon$ while $t^2 - L^2$ is actually $t^2 - L^2 - i\delta$. (That is, we are not introducing at this stage any extra prescription and merely using what is required even in the case of standard QFT, corresponding to $L = 0$.) To evaluate this integral, we have to use the result

$$
I(a, b) = \int_{0}^{\infty} dx \ e^{-i(a - i\epsilon)x^2 - i(b - i\delta)x^2} = \frac{1}{2} \left(\frac{\pi}{ia}\right)^{1/2} \exp\left(-2i\sqrt{a - i\epsilon} \sqrt{b - i\delta}\right)
$$

(5.9)

This integral is well defined for all real $(a, b)$, positive or negative, because of the $\epsilon, i\delta$ regulators. The result can be easily proved when $a$ and $b$ are positive and the result can be analytically continued for, say, $a > 0, b < 0$ (which is the case we are interested in) as well. This leads to the result

$$
\int G_{QG}(x_2; x_1)e^{-ip \cdot x} d^3x = \frac{1}{2\omega_p} \exp(-i\omega_p \sqrt{t^2 - L^2 - i\delta})
$$

(5.10)

(Considering the importance of this result I have provided yet another derivation, by analytic continuation from the Euclidean sector — where we do not need the $\epsilon, i\delta$ regulators
and integrals are well-defined — in the appendix.) Inverting the Fourier transform in eq. (5.10), we can write

$$G_{QG}(x_2; x_1) = \int \frac{d^3p}{(2\pi)^3 2\omega_p} e^{i p \cdot x} e^{-i \omega_p \sqrt{t^2 - L^2} - i \delta}$$

(5.11)

As we had noted before, the Schwinger representation (and its explicit evaluation in terms of modified Bessel function) tells us that the left hand side of this equation is well defined. On the right hand side no issues arise when $t^2 > L^2$. When $t^2 < L^2$ the square root has to be defined as $-i \sqrt{L^2 - t^2}$ so that the integral is exponentially damped for large values of $|p|$. This is a consistent interpretation of the branch-cut of the square root in complex plane.

The same result can also be obtained (more rigorously) from our result in eq. (2.14). If we replace $|t|$ by $\sqrt{t^2 - L^2}$ on both sides, we get the integral representation:

$$U_{QG}(t) = f[H, \sqrt{t^2 - L^2}] = e^{-i H \sqrt{t^2 - L^2}} = \int_{-\infty}^{\infty} ds \left( \frac{i \pi}{2} \right) \left[ \frac{s}{t^2 - L^2 - s^2 - i \epsilon} \right] e^{-i H s}$$

(5.12)

Since the function $f(H, z)$ is defined everywhere in the complex plane of $z$, this representation is defined for both signs of $(t^2 - L^2)$. Since $f(H, z = iy) = e^{-H|y|}$ for positive definite $H$ and $y$ real, it follows that $U_{QG}(t) = e^{-H \sqrt{L^2 - t^2}}$ for $t^2 < L^2$.

Therefore, our result strongly suggests the interpretation of the evolution operator as:

$$G_{QG}(x_2, x_1) = \begin{cases} 
(x_2 | e^{-i H \sqrt{t_2 - t_1}} | x_1) & \text{for } t_2 > L^2 \\
(x_2 | e^{-H \sqrt{L^2 - t_1}} | x_1) & \text{for } t_2 < L^2 
\end{cases}$$

(5.13)

Clearly the time evolution operator is not unitary for $|t_2 - t_1| < L$, i.e. at sub-Planckian scales. While this is intriguing, there has been some discussion in the literature about such possibilities. For example, ref. [32] discusses the origin of non-unitary evolution in the context of several quantum gravity models and attempts to identify the origin of such behaviour. The results here, however, do not seem to be directly related to the models considered in ref. [32]. In fact, our result seems to be rather generic, if we accept the extrapolation of our construction from mesoscopic scales to sub-Planckian scales. On the other hand, there have been suggestions in the literature [17, 27–31] that the QG-corrected (effective) metric could make the spacetime Euclidean at sub-Planckian scales. This idea seems to be conceptually closer to our results. These connections certainly need to be explored further, checked for inconsistencies etc. and I hope to address these questions in a future work.

A QFT Propagator without QF

The complete dynamics of spinless particle of mass $m$, in a curved spacetime with metric $g_{ab}$ is contained in the propagator $G_{\text{std}}(x_2, x_1)$, or, equivalently, in the rescaled propagator $\mathcal{G} \equiv m G_{\text{std}}$. (The latter will turn out to be simpler to handle algebraically.) I will now introduce three definitions for this propagator, which are robust enough to survive (and be useful) at mesoscopic scales.

All these three, equivalent, ways of defining this propagator works without using the notion of a local quantum field operator, canonical quantisation, vacuum state etc. The first definition of the (Euclidean) propagator is given by:

$$G_{\text{std}}(x,y;m) \equiv m G_{\text{std}}(x,y;m^2) = \int_0^\infty m \, ds \, e^{-m^2 s} K_{\text{std}}(x,y;s)$$

where $K_{\text{std}}$ is the zero-mass, Schwinger (heat) kernel given by $K_{\text{std}}(x,y;s) \equiv \langle x | e^{s \Box_g} | y \rangle$. Here $\Box_g$ is the Laplacian in the background space(time. This heat kernel is a purely geometric object, determined by the background geometry. It has the form (in $D = 4$):

$$K_{\text{std}}(x,y;s) \propto e^{-\bar{\sigma}^2(x,y)/4s} \left[ 1 + \text{curvature corrections} \right]$$

where $\bar{\sigma}^2(x,y)$ is the geodesic distance. The curvature corrections, encoded in the Schwinger-Dewitt expansion, will involve powers of $(s/L_{\text{curv}}^2)$. The exponential $e^{-m^2 s}$ in eq. (A.1) suppresses the integral for $s > \lambda_c^2$ (where $\lambda_c = \hbar/mc$ is the Compton wavelength of the particle) and hence, when $\lambda_c \ll L_{\text{curv}}$, the curvature corrections will be small.

The second definition of the propagator we can use is based on the path integral sum:

$$G_{\text{std}}(x_1,x_2;m) = \sum_{\text{paths } \sigma} \exp -m \sigma(x_1,x_2)$$

where $\sigma(x_1,x_2)$ is the length of the path connecting the two events $x_1, x_2$ and the sum is over all paths connecting these two events. This sum can be defined in the lattice and computed — with suitable measure — in the limit of zero lattice spacing [1, 8, 9]. The result will, of course, agree with that in eq. (A.1).

The third definition is an interesting variant of this which has not been explored in the literature. This is obtained by converting the path integral to an ordinary integral. To do this, let us introduce a Dirac delta function into the path integral sum in eq. (A.3) and

---

10 Notation: i will add the subscript ‘std’ for quantities pertaining to a classical gravitational background, not necessarily flat spacetime; the subscript ‘QG’ will give the corresponding quantities with quantum gravitational correction. For expressions corresponding to a free quantum field in flat spacetime I use the subscript ‘free’.

11 Doing some reverse-engineering, it is possible to obtain the $G_{\text{QG}}$ as a two-point-function of a highly nonlocal field theory; see eq 37 of [34]. But the non-locality of the theory makes it difficult to analyze it along standard lines.

12 In this appendix, I will work in a Euclidean space(time) and will assume that the results in spacetime arise through analytic continuation. This is not crucial and one could have done everything in the Lorentzian spacetime itself.
use the fact that both $\ell$ and $\sigma$ are positive definite, to obtain:

$$G_{\text{std}}(x_1, x_2; m) = \int_0^{\infty} d\ell \ e^{-m\ell} \sum_{\text{paths } \sigma} \delta_D (\ell - \sigma(x_2, x_1)) \equiv \int_0^{\infty} d\ell \ e^{-m\ell} N_{\text{std}}(\ell; x_2, x_1) \quad (A.4)$$

where I have defined the function $N_{\text{std}}(\ell; x_2, x_1)$ to be:

$$N_{\text{std}}(\ell; x_2, x_1) \equiv \sum_{\text{paths } \sigma} \delta_D (\ell - \sigma(x_2, x_1)) \quad (A.5)$$

The last equality in eq. (A.4) converts the path integral to an ordinary integral with a measure $N(\ell)$ which — according to eq. (A.5) — can be thought of as counting the effective number of paths of length $\ell$ joining the two events $x_1$ and $x_2$. Usually, I will just write $N(\ell)$ without displaying the dependence on the spacetime coordinates to keep the notation simple.

Let me illustrate the form of $N(\ell)$ in the case of a free field in flat space. Expressing both $G_{\text{free}}(p, m) = m(p^2 + m^2)^{-1}$ and $N_{\text{free}}(p, \ell)$ in momentum space, we see that:

$$G_{\text{free}}(p^2, m) = mG_{\text{free}}(p^2, m^2) = \frac{m}{m^2 + p^2} = \int_0^{\infty} d\ell \ e^{-m\ell} \cos p\ell \quad (A.6)$$

That is, the $N_{\text{free}}(p, \ell)$ in momentum space is given by the simple expression $N_{\text{free}}(p, \ell) = \cos(p\ell)$. (The form of $N_{\text{free}}(\ell, x_2, x_1)$ in real space can also be computed in closed form by a Fourier transform; see e.g., [33].)

It is easy to understand how the introduction of zero-point-length into the geometry modifies the propagator in eq. (A.4). The existence of the zero-point-length suggests that we should change the path length $\ell$ appearing in the amplitude to $(\ell^2 + L^2)^{1/2}$. Therefore the quantum corrected propagator will be given by the last integral in eq. (A.4) with this simple replacement. This leads to the expression for the propagator incorporating the zero-point-length:

$$G_{\text{QG}}(x_1, x_2; m) = \int_0^{\infty} d\ell \ N_{\text{std}}(\ell; x_1, x_2) \exp \left(-m\sqrt{\ell^2 + L^2}\right) \quad (A.7)$$

The modification $\ell \to (\ell^2 + L^2)^{1/2}$ ensures that all path lengths are bounded from below by the zero-point-length.14

The original path integral in eq. (A.4) had an equivalent description in terms of the heat kernel through eq. (A.1). The modification in eq. (A.7) translates to a modified relation between the heat kernel and the propagator. With some elementary algebra, involving Laplace transforms [33], one can show that eq. (A.7) is now replaced by:

$$G_{\text{QG}}(x, y; m) = \int_0^{\infty} m \ ds \ e^{-m^2 s - L^2/4s} K_{\text{std}}(s; x, y) \quad (A.8)$$

This was the result, eq. (3.1), used in the main text.

13The actual number of paths, of a specified length, connecting any two points in the Euclidean space, is either zero or infinity. But the effective number of paths $N(\ell)$, defined as the inverse Laplace transform of $G$ (see eq. (A.4)), will turn out to be a finite quantity.

14One can also obtain the same result by modifying $N_{\text{std}}$ to another expression $N_{\text{QG}}$ and leaving the amplitudes the same. But the above interpretation is more intuitive.
Again, let me illustrate both eq. (A.7) and eq. (A.8) — which are actually valid in arbitrary curved spacetime — in the simple context of a free field in flat spacetime. In the momentum space we can use the result $N_{\text{free}}(p, \ell) = \cos pl$ in eq. (A.7), to get:

$$G_{\text{QG}}(p^2) = \int_0^\infty d\ell \ e^{-m\sqrt{L^2 + \ell^2}} \cos(pl) = \frac{mL}{\sqrt{p^2 + m^2}} K_1[L\sqrt{p^2 + m^2}]$$  \hspace{1cm} (A.9)

Similarly, using the expression for zero-mass, flat-space kernel in the momentum space $K_{\text{std}}(s; p) = \exp(-sp^2)$ in eq. (A.8) we find that:

$$G_{\text{QG}}(p^2) = \int_0^\infty ds \ m \ \exp\left[-s(p^2 + m^2) - \frac{L^2}{4s}\right] = \frac{mL}{\sqrt{p^2 + m^2}} K_1[L\sqrt{p^2 + m^2}]$$  \hspace{1cm} (A.10)

which is identical to eq. (A.9). These expressions describe the QG corrections to the propagator in a freely-falling-frame [33].

The propagator with zero-point-length also has an elegant path integral description [8, 9]. A heuristic way of obtaining this is as follows: the path integral in eq. (A.3) implies that the amplitude is exponentially suppressed for paths longer than the Compton wavelength $\lambda_c \equiv h/mc$. This is due to the fact that the action for a relativistic particle of mass $m$ leads to the factor $\exp(-A/h)$ with $A/h = -m\sigma/h = -\sigma/\lambda_c$ where $\sigma$ is the length of the path and $\lambda_c = h/2mc$ is the Compton wavelength of the particle. There is also another length scale — viz. the gravitational Schwarzschild radius $\lambda_g \equiv Gm/c^2$ — which we can associate with a particle of mass $m$. It makes absolutely no sense to sum over paths with $\sigma \gtrsim \lambda_g$ in the path integral. Just as paths with $\sigma \gtrsim \lambda_c$ are suppressed exponentially by the factor $\exp[-(\sigma/\lambda_c)]$, it is necessary to suppress exponentially the paths with $\sigma \lesssim \lambda_g$ by another exponential\footnote{Why this factor should also be exponential, rather than of some other functional form, is a nontrivial question and is closely related to principle of equivalence. It is explained in detail in ref. [33].} factor $\exp[-(\lambda_g/\sigma)]$. So, a natural and minimal modification of the path integral sum in eq. (A.3), which incorporates the Schwarzschild radius of a particle of mass $m$, will lead to the path integral sum:

$$G(x_1, x_2) \equiv \sum_{\text{paths } \sigma} \exp\left[-\frac{\sigma}{\lambda_c}\right] \exp\left[-\frac{\lambda}{\sigma}\right] = \sum_{\text{paths } \sigma} \exp\left[-m\left(\frac{L^2}{\sigma}\right)\right]$$  \hspace{1cm} (A.11)

where $L = \mathcal{O}(1)L_P$. This path sum can also be evaluated on a lattice [8, 9] and leads to the same expression for $G_{\text{QG}}$ as the two previous definitions. The path integral, given by eq. (A.11) also has a beautiful symmetry: the amplitude is invariant under the duality transformation $\sigma \rightarrow L^2/\sigma$.

\section*{B Analytic continuation to Lorentzian sector}

In this appendix, I will briefly outline how the different results in the Lorentzian sector, used in the main text, arises from the analytic continuation from the Euclidean sector. To begin with, let me write down the Schwinger representation for the propagator in the
Euclidean sector by Fourier transforming \( G_{\text{GQ}}(p^2) = \mathcal{G}_{\text{QG}}(p^2)/m \) in eq. (A.10) with respect to \( p \). Evaluating the Gaussian integrals immediately gives:

\[
G_{\text{GQ}}(x) = \frac{1}{16\pi^2} \int_0^\infty \frac{ds}{s^2} \exp \left( -sm^2 - \frac{x^2 + L^2}{4s} \right) \quad (B.1)
\]

In the Euclidean sector \( x^2 = t_E^2 + |x|^2 \) which goes over to \(-t^2 + |x|^2 = -x^2\) on analytic continuation with our mostly negative signature. Further \( s \) is replaced by \( is \) (which is easy to see from the fact that \( e^{-m^2 s} \) should go over to \( e^{-im^2 s} \)). So, analytic continuation of eq. (B.1) gives:

\[
G_{\text{GQ}}(x) = \int_0^\infty \frac{ds}{16\pi^2 i} \exp \left( -im^2 s - \frac{i}{4s} (x^2 - L^2) \right) \quad (B.2)
\]

which, of course, is the same as eq. (3.2) used in the main text.

Let me now provide another derivation of the result in eq. (5.11) by working in the Euclidean sector and analytically continuing the result. Since the spatial coordinates are unchanged when we go from Euclidean to Lorentzian sector, we can start with the spatial Fourier transform of Euclidean propagator in eq. (B.1). Writing \( x^2 = t_E^2 + |x|^2 \) in eq. (B.1) and evaluating the Gaussian integrals over \( x \), we get:

\[
\int G_{\text{GQ}}(x) e^{-ip \cdot x} d^3 x = \frac{1}{\sqrt{4\pi}} \int_0^\infty \frac{ds}{\sqrt{s}} \exp \left( -\omega_p^2 s - \frac{t_E^2 + L^2}{4s} \right) = \frac{1}{\sqrt{\pi}} \int_0^\infty d\rho \exp \left( -\omega_p^2 \rho^2 - \frac{t_E^2 + L^2}{4\rho^2} \right) \quad (B.3)
\]

where \( \omega_p^2 = p^2 + m^2 \) and we have substituted \( s = \rho^2 \) to get the last expression. This integral, of course is perfectly well defined without requiring any regulators and can be evaluated using the standard result:

\[
\int_0^\infty dx \exp \left( -A^2 x^2 - B^2 \right) = \frac{1}{2\pi} \exp (-2|A||B|) \quad (B.4)
\]

This immediately gives the final answer in the Euclidean sector:

\[
\int G_{\text{GQ}}(x) e^{-ip \cdot x} d^3 x = \frac{1}{2\omega_p} \exp \left( -\omega_p \sqrt{t_E^2 + L^2} \right) \quad (B.5)
\]

The analytic continuation to the Lorentzian sector involves the replacement:

\[
\omega_p \sqrt{t_E^2 + L^2} \rightarrow \omega_p \sqrt{-t^2 + L^2} = i\omega_p \sqrt{t^2 - L^2} \quad (B.6)
\]

which reproduces the result in eq. (5.11) without the use of regulators for integrals etc. The sign of the square root in taken to be positive in eq. (B.6) in order to reproduce the standard QFT result when \( L = 0 \), along the lines of eq. (5.4).

Finally, I provide another integral representation for the time evolution operator \( \exp(-iH\sqrt{t^2 - L^2}) \) from the Fourier space expression for the propagator. To do this we compute the Fourier transform of \( \exp(-iH\sqrt{t^2 - L^2}) \) with respect to \( t \) by multiplying both
sides of eq. (3.10) by $e^{i\nu t}$ and integrating over $t$ along the whole real line. We find, after some simple algebra that

$$
\int_{-\infty}^{\infty} dt \ e^{i\nu t-iH\sqrt{t^2-L^2}} = 2H \int_0^{\infty} d\rho \ \exp \left( -i\rho(H^2 - \nu^2 - i\epsilon) + \frac{i(L^2 - i\delta)}{4\rho} \right)
$$

$$
= \frac{2H}{i} \left[ \frac{L^2}{4(H^2 - \nu^2)} \right]^{1/2} K_1 \left( \sqrt{L^2(H^2 - \nu^2)} \right) \equiv F_\nu(L,H) \quad (B.7)
$$

In the first equality we have explicitly displayed the $i\epsilon, i\delta$ factors which ensures convergence. In the final expression it is understood that $H^2 = H^2 - i\epsilon$ and $L^2 = L^2 - i\delta$. This allows us to write:

$$
e^{-iH\sqrt{t^2-L^2}} = \int_{-\infty}^{\infty} \frac{d\nu}{2\pi} F_\nu(L,H)e^{-i\nu t} \quad (B.8)
$$

It is straightforward to verify that (since $K_1(z) \approx (1/z)$ as $z \to 0$), eq. (B.8) reduces to standard result in the limit of $L \to 0$, as it should. This expression, with $H^2$ replaced by $-\omega_p^2$ also provides an explicit realization of the result mentioned in eq. (3.5).
