Objective: *P. norvegensis* is increasingly isolated from hospital settings, especially from immunocompromised patients. Understanding the rare pathogen, including its emergence and distribution, is crucial for accurate diagnosis and infection prevention. We studied the genetic diversity of a large collection of clinical *P. norvegensis* isolates obtained from Dutch hospitals along with a set of non-Dutch clinical and environmental isolates.

Methods: Clinical (n = 236, 90.8%) and environmental (n = 24, 9.2%) *P. norvegensis* isolates were subjected to Amplified Fragment Length Polymorphism (AFLP) fingerprinting and a novel six-locus microsatellite typing panel. Data were analyzed with BioNumerics and Structure. We applied a novel mating type assay to determine the MAT loci locus presence/absence.

Results: AFLP fingerprinting separated the *P. norvegensis* isolates into three main clusters. Two clusters fully consist of clinical isolates, the third represented a mix of clinical and environmental isolates. By microsatellite typing, the overall genetic diversity was low (Simprof D = 0.93), due to a large number of Dutch clinical isolates with similar genotypes. Minimum spanning tree analysis showed that Dutch clinical isolates fell into two clusters. Environmental and non-Dutch isolates were more distantly related. Structure analysis showed the presence of four genotypes, with signs of genetic admixture between geographic locations and environmental/clinical isolates. Nearly all isolates harbor the MATα mating type allele.

Conclusions: The *P. norvegensis* isolates obtained from Dutch hospitals appear to be largely clonal, independent of geographic origin and isolation date. The observed clonality is supported by the common number of MLEIs isolates. Microsatellite typing indicated potential admixture between clinical and environmental isolates.

First report of Mycetoma due to Madurella fahalii from India

Vivekumar Hallur, Priyanka Gahlot, Chandra Sekar Srika, Supriya Sahu, Malati Tudu
All India Institute of Medical Sciences, Bhubaneswar, Bhubaneswar, India

Poster session 2, September 22, 2022, 12:30 PM - 1:30 PM

Objective: To describe the first case report of Madurella fahalii from India.

Methods: A 70-year-old non-diabetic man from Madhoik Ghisha who worked as a soldier in past came to us with a history of pus discharge containing black grains of size of sand enclosed in pus in the posterior aspect of the thigh for last 3 years. He had been operated 2 years back for the same complaints, however, finding no relief he treated us. On examination, a deformed lesion measuring 10 x 10 cm, containing 6-8 masses which discharged pinkish yellow colored pus containing black grains measuring 0.5 x 1 cm was found on the posterior aspect of the thigh. The lesion was painless, doughy in consistency, and associated with enlarged and non-swollen and non-tender inguinal lymph nodes measuring 2 x 2 cm. General physical examination and routine histological laboratory examination revealed no abnormalities. Serological tests did not reveal the presence of HPP, Hepatitis B, or Hepatitis C. A clinical diagnosis of black gram mycetoma was made and the patient was sent to microbiology laboratory for fungal culture. Black bird grains were found on KOH mount and culture on inhibitory mold agar grow a brown colony which diffused a brown pigment into the medium after 15 days of incubation. LPHR examination showed brown non-sporulating mold. DNA was extracted using phenol-chloroform-isooamyl alcohol after grinding the infected site in liquid nitrogen and subjected to PCR using LPHR and ITS1 primers as described previously. The product was subjected to agarose sequencing and subjected to blast and it showed 99.45% similarity to M. fahalii (MPP8663). The patient was started on Itraconazole in low of resistance as the patient could not afford the drug. While there is no reduction in the size of the lesion the patient reported symptomatic relief and is still on follow-up.

Conclusions: To the best of our knowledge this is the first case of Mycetoma due to M. fahalii from India.

Fungal Isolates of the respiratory tract in symptomatic patients hospitalized in pulmonary units: A mycological and molecular epidemiologic study

Seyed Jamal Hashemi
Tehran University of Medical Sciences, Tehran, Iran

Poster session 2, September 22, 2022, 12:30 PM - 1:30 PM

Objective: Fungal respiratory infections are being recognized with increasing frequency in parallel with an expanding population of immunocompromised patients. In most cases, colonization is the first step in the progression to pulmonary fungal infection. This study was designed to evaluate the distribution of fungal elements in the respiratory tract of symptomatic patients hospitalized in pulmonary units.

Methods: This descriptive cross-sectional study was carried out over a period of 2 years, from October 2019 to October 2021 in Gahlistan province, located in Iran’s northern region. In the current study, bronchoscopy lavage or sputum specimens were collected. All samples were analyzed by direct microscopy using KOH 10% and culture. Fungal identification was accomplished by internal transcribed spacer (ITS) and β-tubulin sequencing. Also, in patients suspected of invasive pulmonary aspergillosis, BAL specimens were tested for galactomannan (GM) antigen.

Results: A total of 84 lung specimens (192 bronchoalveolar lavage (BAL) and 192 sputum samples) were obtained from symptomatic patients hospitalized in pulmonary units. Of these, 137 (15.67%) were positive in direct examination and cultures. Among the 137 positive cases, most isolates were from male patients 86 (62.77%) and most of them were between 66 and 72 years. Candida albicans (57.22%) and C. tropicalis (21.89%) represent the two most commonly isolated species in the current study. Cough (84.16%), sputum (80.02%), pulmonary spore (62.94%), and weight loss (59.2%) were the predominant symptoms and complications (21.89%), dementia (21.89%) and diabetes mellitus (19.70%) were the predominant underlying conditions. Also, 5 cases of invasive pulmonary aspergillosis and 2 cases of mucormycosis were diagnosed.

Conclusions: Candida albicans was the most common fungal species isolated from symptomatic patients hospitalized in pulmonary units. Tuberculosis, chemotherapy and diabetes mellitus were important underlying conditions for pulmonary fungal colonization and/or infection.

Poster session 2, September 22, 2022, 12:30 PM - 1:30 PM

Backgrounds: The pandemic of COVID-19 has created a global public health crisis. ICU patients with COVID-19 are prone to infections of bacterial and fungal origin due to several risk factors. Consequently, the current study was conducted to evaluate the frequency, demographic characteristics, underlying conditions, and etiologic agents of fungal and bacterial co-infections of the respiratory tract among ICU patients with COVID-19 in Iran.

Materials and Methods: From May to October 2020, sputum and middle-tracheal aspirates were collected from ICU patients hospitalized with COVID-19 who also were suspected of bacterial and/or fungal co-infections according to inclusion criteria. The etiologic agents of bacterial co-infections were identified using the VITEK 2 identification method. For fungal identification, all samples were analyzed by direct microscopy using KOH 10% and culture. Furthermore, all isolates were subjected to the sequencing method.

Results: A total of 73 lung specimens were obtained from patients who met the inclusion criteria. Of these, in 15 cases (20.54%) fungal and/or bacterial co-infections were confirmed. Males were more infected (75.33%) and all of them were between 49 and 79 years. Candida albicans (n = 8, 61.53%) and Klebsiella pneumonia (n = 5, 38.46%) were the most frequent etiologic agents related to fungal and bacterial co-infections, respectively. Pneumocystis (n = 15, 100%) and diabetes mellitus (n = 8, 53.33%) were documented as the most prevalent underlying conditions. In the current study, 5 out of 15 patients (33.33%) died.

Conclusions: The frequency of bacterial-fungal co-infections of the respiratory tract in ICU patients hospitalized with COVID-19 was relatively high. According to the results, one of the causes of death in these patients could be a secondary infection.
