INTRODUCTION

Many periodontal plastic surgery techniques and flap designs have been proposed to obtain a highly predictable and long-term root coverage by augmenting gingival tissue dimensions. Among the available techniques, the conventional coronally advanced flap (CCAF) associated with a connective tissue graft (CTG) is considered a gold standard technique with a significantly higher percentage of root coverage and keratinized tissue gain. However, CTG harvesting is associated with increased patient morbidity, prolonged surgical time and postoperative complications (bleeding, numbness and sensibility changes in the donor area)⁹). 

Mucograft® is a reconstructive porcine matrix composed of a bilayer structure of collagen type I and type III, which acts as a substitute in cases of loss of the connective tissue structure around teeth and implants. This collagen matrix (CM) guarantees unlimited availability, surgical time decrease and fewer postoperative complications due to the lack of a donor site¹⁰). A recent systematic review and meta-analysis showed that no significant differences were detected in the percentage of mean root coverage (MRC) and recession reduction (RR) between CM and CTG in single or multiple recession. Nevertheless, a higher percentage of complete root coverage (CRC) and greater keratinized tissue (KT) gain could be observed in the CTG group at multiple recessions¹¹).

The platelet-rich fibrin (PRF) is an autologous fibrin matrix containing 50% of the leukocytes from the original blood volume. This three-dimensional fibrin matrix acts as a support for the cells during the regenerative process³). Moreover, in vitro studies have demonstrated a slow release of several growth factors including transforming growth factor β1, platelet-derived growth factor and vascular endothelial growth factor during the first 7 days in sterile medium⁴). In general, clinical studies have shown that CCAF alone or in combination with the PRF membrane are highly predictable procedures for the treatment of Miller Class I and II gingival recessions. However, the use of PRF membrane resulted in enhanced soft-tissue healing in terms of colour and tissue texture⁵) and KT gain in comparison to CCAF alone after 6th and 12 months⁶).

Therefore, we proposed the use of PRF as a combination material, based on its potential to enhance fibroblast activity and angiogenesis stimulation, to improve the CM clinical results. Therefore, this case series aimed to present the effect of the CM associated with PRF in the treatment of gingival recessions concerning root coverage and KT gain.

CASE REPORTS

1 Patients Informations

Six non-smokers, systemically healthy patients (4 females, 2 males, aged 20 to 42 years) who had at least one site with single gingival recession (recession type 1 (RT1) class or Miller Class I and II) in the maxilla were included in this case series (Figure 1 and 2). To be included in this case series the patients also required to present less than 20% of plaque index; the gingival recession must be presented in canine or premolar tooth in the ideal position (without individual malpositions according to Lischer Classification¹⁶) and a negative history of previous surgical procedures or periodontal disease. The clinical measurements were made at the mid-buccal point of the involved teeth at baseline (before surgery), 1, 3, 6 and 12 months by the same investigator (M.A.T.A) using the same type of periodontal probe (UNC 15, Hu-Friedy, Chicago, IL, USA).

The following parameters were assessed: (1) gingival recession depth (GRD in mm) measured as the distance from the CEJ to the gingival margin; (2) pocket probing depth (PPD in mm), which was analyzed at the distobuccal, mid-buccal and mesiobuccal aspects of surgical sites, and was considered the distance from the gingival margin to the apical portion of the periodontal sulcus; (3) keratinized tissue width (KTW) (in mm), measured as the distance from the mucogingival junction (MGJ) to the gingival margin; (4) gingival thickness (GT mm) measured 3 mm apically from the free gingival margin at the mid-buccal aspect of the tooth using a dental endodontic hand file (K File Kerr 30mm #10).

2 Therapeutic Intervention

Before the surgical procedure, the PRF membranes’ preparation, according to the technique described by Choukroun et al. (7), was initiated. During the PRF centrifugation (10 minutes at 3000 RPM), local anesthesia was induced using a 4% articaine solution with epinephrine 1:100.000 (Novo DFL). Two different types of flap were used according to the GRD: conventional coronally advanced flap (CCAF) in four larger and wider gingival recessions (GDR greater than 4.00 in Figure 3A and 3B) and modified coronally advanced tunnel (MCAT) in six small and shallower gingival recessions (GDR 1.50 to 2.00) (Figure 3C-G). For the CCAF technique, a trapezoidal full mucoperiosteal flap was raised to the MGJ and a partial thickness flap was made apically to the mucogingival junction (MGJ) allowing a tension-free coronal flap position (Figure 3C-G). The adjacent papillae were de-epithelialized.
(Figure 3F), and the root surface debridement was made using Gracey curettes (Hu-Friedy, RJ, Brazil). For the MCAT, intrasulcular incisions were performed and mucoperiosteal flaps were raised using sharp tunnel elevators preserving the papillae (Quinelato, Brazil) (Figure 4D and 4E). The flap was extended beyond the MGJ and under each papilla allowing a tension-free flap mobilization in the coronal direction (Figure 4F).

After the flap preparation, the CM (Mucograft® collagen matrix, Switzerland) was cut and trimmed to the exact size of the defect, such that ≥1 mm of the surrounding tissue was covered (Figure 3H and 4G). For the CCAF technique, the CM was immobilized in the surgical site with a subperiosteal suture (Marlin® violet, absorbable, DSM 11, 6-0) (Figure 3I). The PRF membrane was also immobilized above to the CM using the same suture (Figure 3J and 3K). For the MCAT technique, both materials (Figure 4H) were sutured together (Figure 4I and 4J) and inserted into the tunnel (Figure 4K). A double-loop sling suture (Resorba® Sutures Resolon™, blue, USP 6/0) was made in the flap interdental region to positioned at or coronal to the cemento-enamel junction (Figure 3L and 4L). Only for the CCAF technique were additional interrupted sutures made in the release incision (Figure 3L). After 15 days, the post-surgery course was uneventful and the sutures were removed. The comparison between the baseline and final clinical appearance of three cases is shown in Figures 1 and 2.

3 Follow-up and Outcomes

A total of 10 gingival recessions were treated in this case series and included in the statistical analysis (tooth-level analysis). Of these, four gingival recessions were treated with CCAF and six gingival recession with the MCAT technique. The GraphPad Prism 6 software (San Diego, CA, USA) was used. The Friedman test complemented by the Dunn test was used to evaluate clinical parameters longitudinally. Comparison between CCAF and MCAT techniques was made using Mann-Whitney Test. Differences were considered statistically significant when the p-value was <0.05.

The median and 25th and 75th percentiles of periodontal clinical parameters at baseline, 1, 3, 6 and 12 months were showed in Table 1. The association between the PRF and CM promoted a reduction in the GRD (2.00 mm (1.50–3.50) to 0.00 (0.00–0.00)) and PPD (1.25 mm (1.00–2.00) to 1.00 mm (1.00–1.62)) resulting in complete root coverage in all gingival recessions after 1 month (Table 1). Moreover,
an increase in KTW (1.25 mm (1.00–2.00) to 1.75 (1.37–2.62)) and GT (1.00 mm (0.50–1.50) to 1.70 (1.27–3.32)) were also observed after 1 month (Table 1). However, apical displacement of the marginal gingival of 0.50 (0.00–1.00) associated with a GT reduction (1.35 (0.90–1.82)) was observed after 12 months. The KTgw gain obtained with the surgical procedure was maintained after 12 months (1.75 (1.37–2.25) (Table 1). The median and 25th and 75th percentiles of periodontal clinical parameters in the CCAF and MCAT techniques groups at baseline, 1, 3, 6 and 12 months were shown in Table 2. Comparing CCAF and MCAT techniques groups, no difference was observed in the GRD, PPD and GT in all analyzed periods (Table 2). A higher increase in the KTgw was observed in the CCAF group in comparison to the MCAT technique in all analyzed periods (Table 2).

**DISCUSSION AND CONCLUSION**

Clinical studies have shown that the use of the CTG ensures superior clinical outcomes in comparison to the PRF and CM alone in gingival recession treatment(8, 9). Based on that, the main aim of this case series was evaluated the association between CM and PRF in the treatment of gingival recessions. To our knowledge, no clinical study series was evaluated the association between CM and PRF in the recessions treatment(8, 9). Based on that, the main aim of this case series was to assess the association between CM and PRF, evaluating the case series seems not to have shown superior root coverage in comparison to CM or CTG alone.

In this case series, the minimal KTgw gain obtained with the surgical procedure was maintained after 12 months (1.25 mm (1.00–2.00) to 1.75 mm (1.37–2.25)). Likewise, Moreira et al. (2016)(12) showed a KTgw gain of 0.20 mm after 6 months with CM alone. However, higher KTgw gain of 1.23 mm and 1.05 mm was observed using CCAF+CM by Cardaropoli et al. (2012)(13) and Stefanini et al. (2016)(11) after 12 months, respectively. For the GT parameter, a statistically significant reduction in the GT gain was observed between 1 and 12 months, with a minimum GT gain obtained after 12 months (1.00 mm (0.50–1.50 to 1.35 (0.90–1.82))). Minimal GT gain was also shown by Stefanini et al. (2016) (11) (0.52 mm) after 12 months and by Moreira et al. (2016)(12) (0.40 mm) after 6 months. However, superior results were reported by Cardaropoli et al. (2012)(13) that obtained a gain of 1.00 mm in GT for CM and 1.23 mm for CTG after 12 months. Consequently, the KTgw and GT results obtained in this case series also suggested that the PRF membrane did not increase CM clinical potential. This fact can be associated with the relatively rapid degradation of the PRF membrane, with the subsequent reduction in molecule release(14), which could negatively interfere in the PRF potential to improve the soft-tissue healing in the long term.

For the small and shallow gingival recession, the MCAT was proposed which avoids vertical releasing incisions and does not incise the papillae, which in turn may improve vascularization of the area. This technique ensures a premature esthetic result and satisfactory healing, however, should be avoided in large recesses to avoid excessive graft exposure(15). A significantly higher increase in the KTgw was observed in the CCAF group in comparison to the MCAT technique in all analyzed periods. This can be attributed to the natural tendency of the MGJ to regain its original, genetically determined position once the CCAF technique promotes a higher coronal repositioning of the MGJ due to the vertical releasing incisions.

Within the limits of this case series, it is concluded that the association between the CM and PRF was effective for the treatment of Miller Class I and II gingival recession.

### Table 1: Median and 25th and 75th percentiles of periodontal clinical parameters at baseline, 1, 3, 6 and 12 months.

| Parameter/Period       | Baseline | 1 month | 3 months | 6 months | 12 months |
|------------------------|----------|---------|----------|----------|-----------|
| Gingival Recession Depth | 2.00 (1.50 – 3.50)* | 0.00 (0.00 – 0.00) | 0.50 (0.00 – 0.50)* | 0.50 (0.00 – 1.00) | 0.50 (0.00 – 1.00)* |
| Pocket probing depth   | 1.25 (1.00 – 2.00) | 1.00 (1.00 – 1.62) | 1.25 (1.00 – 1.62) | 1.25 (1.00 – 1.62) | 1.25 (1.00 – 1.62) |
| Keratinized Tissue Width | 1.25 (1.00 – 2.00)* | 1.75 (1.37 – 2.62)* | 1.75 (1.37–2.25)* | 1.75 (1.37–2.25)* | 1.75 (1.37–2.25)* |
| Gingival thickness     | 1.00 (0.50 – 1.50)* | 1.70 (1.27 – 3.23)* | 1.45 (0.95 – 2.00)* | 1.35 (0.90 – 1.82)* | 1.35 (0.90 – 1.82)* |

MCAT: Modified Coronally Advanced Tunnel; CCAF: Conventional Coronally Advanced Flap; a, b: Different letters represent statistically significant differences between each follow-up period (p<0.05- Friedman and Dunn Test); *p<0.05; **p<0.01- Intergroup statistically significant differences– Mann- Whitney Test.
Association between platelet-rich fibrin and collagen matrix for root coverage: Case Series.

CLINICAL RELEVANCE

Clinical studies have demonstrated that the use of the connective tissue graft (CTG) ensure superior clinical results in comparison to the platelet-rich fibrin (PRF) and collagen matrix (CM) alone in the gingival recessions treatment. Based on that, the present case series proposed the use of PRF as a combination material, based on its potential to enhance fibroblast activity and angiogenesis stimulation, to improve the CM clinical results in the treatment of gingival recessions.

CONFLICT OF INTEREST AND FUNDING SOURCE
