ON THE COMPUTATIONAL COMPLEXITY OF NON-DICTATORIAL AGGREGATION

LEFTERIS KIROUS1, PHOKION G. KOLAITIS2, AND JOHN LIVIERATOS1

ABSTRACT. We investigate when non-dictatorial aggregation is possible from an algorithmic perspective, where non-dictatorial aggregation means that the votes cast by the members of a society can be aggregated in such a way that there is no single member of the society that always dictates the collective outcome. We consider the setting in which the members of a society take a position on a fixed collection of issues, where for each issue several different alternatives are possible, but the combination of choices must belong to a given set $X$ of allowable voting patterns. Such a set $X$ is called a possibility domain if there is an aggregator that is non-dictatorial, operates separately on each issue, and returns values among those cast by the society on each issue. We design a polynomial-time algorithm that decides, given a set $X$ of voting patterns, whether or not $X$ is a possibility domain. Furthermore, if $X$ is a possibility domain, then the algorithm constructs in polynomial time a non-dictatorial aggregator for $X$. Furthermore, we show that the question of whether a Boolean domain $X$ is a possibility domain is in NLOGSPACE.

We also design a polynomial-time algorithm that decides whether a $X$ is a uniform possibility domain, that is, whether $X$ admits an aggregator that is non-dictatorial even when restricted to any two positions for each issue. As in the case of possibility domains, the algorithm also constructs in polynomial time a uniform non-dictatorial aggregator, if one exists. Then, we turn our attention to the case where $X$ is given implicitly, either as the set of assignments satisfying a propositional formula, or as a set of consistent evaluations of a sequence of propositional formulas. In both cases, we provide bounds to the complexity of deciding if $X$ is a (uniform) possibility domain. Finally, we extend our results to four types of aggregators that have appeared in the literature: generalized dictatorships, whose outcome is always an element of their input, anonymous aggregators, whose outcome is not affected by permutations of their input, monotone, whose outcome does not change if more individuals agree with it and systematic, which aggregate every issue in the same way.

1. INTRODUCTION

The study of vote aggregation has occupied a central place in social choice theory. A broad framework for carrying out this study is as follows. There is a fixed collection of issues on each of which every member of a society takes a position, that is, for each issue, a member of the society can choose between a number of alternatives. However, not every combination of choices is allowed, which means that the vector of the choices made by a member of the society must belong to a given set $X$ of allowable voting patterns, called feasible evaluations. The goal is
to investigate properties of **aggregators**, which are functions that take as input the votes cast by the members of the society and return as output a feasible evaluation that represents the collective position of the society on each of the issues at hand. A concrete key problem studied in this framework is to determine whether or not a **non-dictatorial aggregator** exists, i.e., whether or not it is possible to aggregate votes in such a way that no individual member of the society dictates the votes on the society. A set $X$ of feasible evaluations is called a **possibility domain** if it admits a non-dictatorial aggregator; otherwise, $X$ is called an **impossibility domain**. This framework is broad enough to account for several well-studied cases of vote aggregation, including the case of **preference aggregation** for which J. K. Arrow [1] established his celebrated impossibility theorem and the case of **judgment aggregation** (for a survey of the latter, see [14]).

The investigation of the existence of non-dictatorial aggregators is typically carried out under two assumptions: (a) the aggregators are **independent** and (b) the aggregators are **conservative** (also known as **supportive** or **grounded**). The independence assumption means that the aggregator is an issue-by-issue aggregator, so that an independent aggregator on $m$ issues can be identified with an $m$-tuple $(f_1, \ldots, f_m)$ of functions aggregating the votes on each issue. It is not difficult to see that, if independence is not assumed, then non-dictatorial aggregation is trivially always possible. The notion of independence corresponds to that of **independence of irrelevant alternatives** (IIA) used by J. K. Arrow [1] in the preference aggregation framework, under a natural embedding (provided by Dokow and Holzman in [10]) of the preference aggregation framework to the framework described here. The conservativeness (or supportiveness) assumption means that, for every issue, the position returned by the aggregator is one of the positions held by the members of the society on that issue. An immediate consequence of this property, is that the social decision cannot have “compromises” between the choices of the voters.

By now, there is a body of research on identifying criteria that characterize when a given set $X$ of feasible evaluations is a possibility domain, that is, it admits an $m$-tuple of $n$-ary conservative functions that are not all projections to the same coordinate. The first such criterion was established by Dokow and Holzman [11] in the Boolean framework, where, for each issue, there are exactly two alternatives (say, 0 and 1) for the voters to choose from. Specifically, Dokow and Holzman showed that a set $X \subseteq \{0, 1\}^m$ is a possibility domain if and only if $X$ is affine or $X$ is not totally blocked. Informally, the notion of **total blockedness**, introduced first by Nehring and Puppe [33], asserts that the social position on any issue can be inferred from the social position on any issue. This notion appears in many of the characterization results for possibility domains. In the non-Boolean framework (where, for some issues, there may be more than two alternatives), Dokow and Holzman [12] extended the notion of total blockedness and used it to give a sufficient condition for a set $X$ to be a possibility domain. Szegedy and Xu [11] used tools from universal algebra to characterize when a totally blocked set $X$ is a possibility domain. The reason for this is, as Kirousis et al. [24] showed, that total-blockedness corresponds to a weak notion of impossibility, specifically a set $X$ admits a binary non-dictatorial aggregator if and only if $X$ is not totally blocked. A consequence of these results is that a set $X$ is a possibility domain if and only if $X$ admits a binary non-dictatorial aggregator or a ternary non-dictatorial aggregator; in other words, non-dictatorial aggregation is possible for a society of some size if and only if it is
possible for a society with just two members or with just three members. This line of work was pursued further by Kirousis et al. [24], who characterized possibility domains in terms of the existence of binary non-dictatorial aggregators or ternary non-dictatorial aggregators of a particular form.

All the aforementioned results are situated in what Dokow and Holzman call the abstract framework, where the domain $X$ is given explicitly as a set of $m$-ary tuples. Earlier works in this framework include, but are not limited to, [17, 22, 37]. Judgment aggregation has been extensively studied in the framework of the logic-based approach (see [30, 31]). In that approach, there is a tuple $\bar{\phi} = (\phi_1, \ldots, \phi_m)$ of propositional formulas, called the agenda, and the set $X$ of feasible evaluations comprises consistent judgments concerning the validity of the formulas. A judgment over a formula $\phi$ amounts to deciding if $\phi$ or $\neg\phi$ is true and it is consistent if of all the formulas deemed true can be satisfied simultaneously, by at least one assignment of values. Note that in this setting, the allowed positions on each issue are necessarily two and thus it is situated in the Boolean framework. In this framework, Endriss et al. [16] have studied the computational complexity of three interesting problems: the winner determination problem, where we want to decide if a specific formula belongs to the collective decision on a given agenda under some aggregation procedure, the strategic manipulation problem, where we want to decide if an agent has an incentive to misrepresent his or her preferences in order to change the collective decision on a given agenda under some aggregation procedure, and the safety of the agenda problem, where we want to decide if a class of aggregators preserves the logical consistency restrictions of an agenda. This last problem is related to our framework, with the difference that we search for at least one aggregator of a given class preserving the logical restrictions of our domain. Also, [44] have studied the case where the individuals do not need to make a decision on every issue of the agenda, but can instead provide partial judgments.

A different approach is the one used by Grandi and Endriss [18], where the set of restrictions is provided by a propositional formula $\phi$, called an integrity constraint, as the set of its satisfying assignments. The agents here are required in a way to select, in a consistent manner, which variables of the formula are true and which are not, instead of doing so for entire propositional formulas of an agenda. Endriss et al. [15] study the relation of this framework with the logic-based one, in terms of the succinctness of the corresponding languages used and of the computational complexity of the winner determination problem.

Summary of Results. The aforementioned investigations have characterized possibility domains (in both the Boolean and the non-Boolean frameworks) in terms of structural conditions. Our goal is to investigate possibility domains using the algorithmic lens and, in particular, to study the following algorithmic problem: given a set $X$ of feasible evaluations, determine whether or not $X$ is a possibility domain. Szegedy and Xu [41] Theorem 36] give algorithms for this problem, but these algorithms have very high running time; in fact, they run in exponential time in the number of issues and in the number of positions over each issue, even when confined to the Boolean framework.

We design a polynomial-time algorithm that, given a set $X$ of feasible evaluations (be it in the Boolean or the non-Boolean framework), decides whether $X$ is a possibility domain. Furthermore, if $X$ is a possibility domain, then the algorithm produces a binary non-dictatorial or a ternary non-dictatorial aggregator for $X$. 

The first step towards this result is to show that there is a polynomial-time algorithm that given a set $X$ of feasible evaluations, decides whether $X$ admits a binary non-dictatorial aggregator (as mentioned earlier, this amounts to $X$ not being totally blocked). In fact, we show a stronger result, namely, that this problem is expressible in Transitive Closure Logic (TCL), an extension of first-order logic with the transitive closure operator; see [29] for the precise definitions. As a consequence, the problem of deciding whether $X$ admits a binary non-dictatorial aggregator is in NLOGSPACE. Using this result, we then show that the problem of deciding whether a set $X \subseteq \{0,1\}^m$ is a possibility domain is in NLOGSPACE.

After this, we turn our attention to uniform possibility domains, which were introduced by Kirousis et al. [24] and which form a proper subclass of the class of possibility domains. Intuitively, uniform possibility domains are sets of feasible evaluations that admit an aggregator that is non-dictatorial even when restricted to any two positions for each issue. This requirement forces the aggregating procedure to treat each Boolean (yes/no) decision of every issue in a non-dictatorial way. In that way, we can avoid various trivial cases of non-dictatorial aggregation, where different “dictators” are chosen for different sets of positions of an issue. Kirousis et al. established a tight connection between uniform possibility domains and a variant of constraint satisfaction problems by showing that multi-sorted conservative constraint satisfaction problems are tractable on uniform possibility domains, whereas such constraint satisfaction problems are NP-complete on all other domains. Here, using the result by Carbonnel [7], we give a polynomial-time algorithm for the following decision problem: given a set $X$ of feasible evaluations (be it in the Boolean or the non-Boolean framework), determine whether or not $X$ is a uniform possibility domain; moreover, if $X$ is a uniform possibility domain, then the algorithm produces a suitable uniform non-dictatorial aggregator for $X$.

We also study the problems of non-dictatorial and uniform non-dictatorial aggregation in case $X$ is Boolean and provided via an integrity constraint or by an agenda. In both cases, we provide bounds for the computational complexity of deciding if $X$ is a (uniform) possibility domain. Finally, we extend our results to three types of aggregators that have been used in the literature: generalized dictatorships [18], [9], whose outcome is always an element of their input, anonymous aggregators, whose outcome is not affected by permutations of their input and monotone aggregators, whose outcome does not change if more individuals agree with it (see [35]) and, finally, systematic aggregators, which aggregate every issue in the same way. This last type of aggregators corresponds to polymorphisms, that is functions that preserve domains, which have been extensively studied in the literature (e.g., in [42]) and which have been successfully used in matters of computational complexity (e.g., in [34]) and aggregation theory (e.g., in [24,41]).

The results reported here contribute to the developing field of computational social choice and pave the way for further exploration of algorithmic aspects of vote aggregation. In a sense, the question we investigate is the following: given a specific voting scheme, where some pre-defined rules of logical consistency apply, how difficult is it to decide if it is possible to design an aggregation rule with some desired properties, and then construct it in case it is? It should be noted that in the field of Judgment Aggregation, quite frequently the domains that impose the logical consistency restrictions are fixed. In such a setting, the algorithmic approach does not have much to offer, since in this case we have a one-off problem. On the other
hand, it is not difficult to imagine groups of people that constantly need to make collective decisions over different sets of issues, where the logical restrictions that apply change according to the dependencies between the issues. In this scenario, algorithms that can quickly decide which aggregation rules can be applied could be useful.

In terms of the applicability of our algorithms in the abstract setting, there is an issue with the size of the input, since a domain $X$ given explicitly as a set of $m$-ary vectors, can be too large for practical purposes. However, as small or large the domain might be, the search space of its possible aggregators is exponentially larger, even provided characterization results like the ones in [10][24][41] that restrict the search to binary or ternary aggregators. Thus, our tractability results in the abstract framework should be interpreted as showing that, given access to the domain, one encounters no more problems in deciding whether non-dictatorial aggregation is possible. Furthermore, the algorithm for finding and producing binary non-dictatorial aggregators (or deciding their lack thereof), is used in obtaining parts of the complexity upper bounds in the cases where the domain is given in compact form.

Structure of the paper. Theorems, lemmas, and corollaries are numbered per section, each referring to its own type, whereas claims are numbered within theorems.

- In Section 2 we formally describe the abstract framework and the necessary tools used to obtain the polynomial-time algorithms for deciding if a domain $X$ is a (uniform) possibility domain. Specifically, in Subsection 2.1 we state the main theorems we use to obtain our results concerning possibility domains, i.e., the characterizations of possibility domains in the Boolean framework [Theorem A], totally blocked domains [Theorem B], and possibility domains in the non-Boolean case [Theorem C]; we also prove Lemma 2.3 that outlines the type of aggregators for domains that are Cartesian products. In Subsection 2.2 we define uniform possibility domains and state Theorem [1] that characterizes them. In Subsection 2.3 we discuss the Polynomial Hierarchy.

- In Section 3 we present our polynomial time algorithms. Specifically, in Subsection 3.1 we present polynomial time algorithms that check whether a domain admits binary non-dictatorial aggregators [Theorem 3.1], whether a domain is totally blocked [Corollary 3.1], and whether a domain is a possibility domain [Theorem 3.2, first main result]. We also show that all domains admit maximum symmetric aggregators [Lemma 3.3] and give a polynomial time algorithm that produces one [Corollary 3.2]. In Subsection 3.2 we describe Transitive Closure Logic and Least Fixed Point Logic, showing that detecting whether a Boolean domain admits binary non-dictatorial aggregators is in TCL and in LFP [Theorem 3.3], that checking whether a Boolean domain is affine is in LOGSPACE [Lemma 3.6], and that checking whether it is a possibility domain is in NLOGSPACE [Theorem 3.4, second main result]. In Subsection 3.3 we present a polynomial time algorithm that checks whether a domain is a uniform possibility domain [Theorem 3.5, third main result], using a polynomial time algorithm by Carbonnel [7]
that checks whether a domain admits polymorphisms with specific properties [Theorem E]. We also state an alternative characterization of local possibility domains in the Boolean framework [Corollary 3.4] and provide a polynomial time algorithm that checks whether a domain is a local possibility domain [Corollary 3.5].

• In Section 4, we present some complexity results for the case where $X$ is given implicitly, either by an integrity constraint or an agenda. Specifically, in Subsection 4.1, we describe the logic-based framework, defining integrity constraints and agendas. In Subsection 4.2, we define the domain $\text{Imp}$, show that it is an impossibility domain [Lemma 4.2], and prove that the problem of deciding if the domain of an integrity constraint admits non-dictatorial aggregators is in $\Sigma_P^2 \cap \Pi_P^2$ and coNP-hard [Theorem 4.1, fourth main result], whereas the same problem for locally non-dictatorial aggregators is in $\Sigma_P^2 \cap \Pi_P^2$ and coNP-hard [Theorem 4.2, fifth main result]. In Subsection 4.3, we show that the problem of deciding whether the domain of an agenda admits non-dictatorial aggregators is in $\Delta_P^3$ and coNP-hard [Theorem 4.3, sixth main result], whereas the same problem for locally non-dictatorial aggregators is in $\Delta_P^3$ and coNP-hard [Theorem 4.4, seventh main result]. In Subsection 4.4, we state a characterization of Boolean domains admitting aggregators that are not generalized dictatorships [Theorem F] and prove that the problem of deciding whether the domain of an integrity constraint (respectively, agenda) admits aggregators that are not generalized dictatorships is in $\Sigma_P^2 \cap \Pi_P^2$ (respectively, $\Delta_P^3$) and coNP-hard [Corollaries 4.2 and 4.3]. We provide the exact same results for anonymous [Corollaries 4.4 and 4.5] and monotone aggregators [Theorem G and Corollary 4.6]. Finally, we show that deciding whether the domain of an integrity constraint admits systematic aggregators is coNP-complete [Proposition 4.1], whereas that of an agenda is in $\Pi_P^2$ and coNP-hard [Proposition 4.2].

Relation to the conference version. A preliminary version of this paper appeared in the Proceedings of the 17th International Conference on Relational and Algebraic Methods in Computer Science (RAMiCS 2018) [23]. The present full version, in addition to detailed proofs and several improvements in the presentation, contains the results about expressibility in Transitive Closure Logic and membership in NLOGSPACE. Furthermore, all the results in Section 4 concerning the case in which $X$ is given implicitly are new.

2. Preliminaries and Earlier Work

In Subsection 2.1 we consider possibility domains both in the Boolean and non-Boolean case, whereas in Subsection 2.2 we turn our attention to uniform possibility domains.

2.1. Possibility Domains. Let $I = \{1, \ldots, m\}$ be a set of issues. Assume that the possible position values of an individual (member of a society) for each issue are given by the finite set $A$. We also assume that $A$ has cardinality at least 2. If $|A| = 2$, we say that we are in the Boolean framework; otherwise we say that we are in the non-Boolean framework.

An evaluation is an element of $A^m$. Let $X \subseteq A^m$ be a set of permissible or feasible evaluations. To avoid degenerate cases, we assume that for each $j = 1, \ldots, m$, the
j-th projection $X_j$ of $X$ has cardinality at least 2. Notationally, we refer to the elements of $X$ (or sometimes of $A^n$) as vectors, patterns, evaluations or assignments, depending on the context.

Let $n \geq 2$ be the number of individuals. We view each element $x$ of $X^n$ as a $n \times m$ matrix that represent the choices of all individuals over every issue. The element $x_j^i$ of such a matrix $x$ will be the choice of the $i$-th individual over the $j$-th issue, for $i = 1, \ldots, n$ and $j = 1, \ldots, m$. The $i$-th row $x_i^j$ will represent the choices of the $i$-th individual over every issue, $i = 1, \ldots, n$, and the $j$-th column $x_j$ the choices of every individual over the $j$-th issue, $j = 1, \ldots, m$.

In order to aggregate a set of $n$ feasible evaluations, we use $m$-tuples $F = (f_1, \ldots, f_m)$ of $n$-ary functions, where $f_j : X^n_j \to X_j$, $j = 1, \ldots, m$. Such a $m$-tuple $F$ of functions will be called an ($n$-ary) aggregator for $X$ if it satisfies:

1. **Collective rationality**: $(f_1(x_1), \ldots, f_m(x_m)) \in X$.
2. **Conservativity**: $f_j(x_j) \in \{x_1^j, \ldots, x_n^j\}$, for all $j \in \{1, \ldots, m\}$.

An aggregator $F = (f_1, \ldots, f_m)$ is called dictatorial on $X$ if it always outputs a specific vector of its input, that is, if there is a number $d \in \{1, \ldots, n\}$ such that $(f_1, \ldots, f_m) = (pr_d^n, \ldots, pr_d^n)$, where $pr_d^n$ is the $n$-ary projection on the $d$-th coordinate; otherwise, $F$ is called non-dictatorial on $X$. We say that $X$ has a non-dictatorial aggregator if, for some $n \geq 2$, there is a $n$-ary non-dictatorial aggregator on $X$. In such a case, we say that $X$ is a possibility domain. Otherwise, it is an impossibility domain. A possibility domain is, by definition, one where non-dictatorial aggregation is possible for societies of some cardinality, namely, the arity of a non-dictatorial aggregator.

Observe that if $X$ has a non-dictatorial aggregator of arity $n$, then it has also non-dictatorial aggregators of arity $k$, for all $k \geq n$. Indeed, given an $n$-ary non-dictatorial aggregator $F = (f_1, \ldots, f_m)$ for $X$, we can define, for any $k \geq n$, the aggregator $G = (g_1, \ldots, g_m)$ whose components $g_j$ simply ignore the last $k - n$ elements of their input and behave like the corresponding $f_j$’s. On the other hand, Dokow and Holzman [12] provide an example of a domain admitting a ternary non-dictatorial aggregator, but no binary ones.

The notion of an aggregator is akin to, but different from, the notion of a polymorphism – a fundamental notion in universal algebra; see, e.g., [42]. A polymorphism is in fact a systematic aggregator, that is, an aggregator all of whose components are the same operation. Let $A$ be a finite non-empty set. A constraint language over $A$ is a finite set $\Gamma$ of relations of finite arities. Let $R$ be an $m$-ary relation on $A$. A function $f : A^n \to A$ is a polymorphism of $R$ if the following condition holds:

$$\text{if } x^1, \ldots, x^n \in R, \text{ then } (f(x_1), \ldots, f(x_m)) \in R,$$

where $x^i = (x^i_1, \ldots, x^i_m) \in R$, $i = 1, \ldots, n$ and $x_j = (x_j^1, \ldots, x_j^n)$, $j = 1, \ldots, m$.

In this case, we also say that $R$ is closed under $f$ or that $f$ preserves $R$. Finally, we say that $f$ is a polymorphism of a constraint language $\Gamma$ if $f$ preserves every relation $R \in \Gamma$.

In fact, polymorphisms of a domain $X$ correspond to systematic aggregators for $X$, that is, aggregators $F = (f_1, \ldots, f_m)$ where $f_j = \bar{f}$, $j = 1, \ldots, m$. In what follows, we denote $m$-tuples comprised of the same function $f$ by $\bar{f}$.

A function $f : A^n \to A$ is conservative if, for all $a_1, \ldots, a_n \in A$, we have that $f(a_1, \ldots, a_n) \in \{a_1, \ldots, a_n\}$. Clearly, if $f : A^n \to A$ is a conservative polymorphism
of an $m$-ary relation $R$ on $A$, then the $m$-tuple $f = (f, \ldots, f)$ is an $n$-ary aggregator for $R$.

We say that a ternary operation $f : A^3 \to A$ on an arbitrary set $A$ is a majority operation if for all $x$ and $y$ in $A$,
\[
f(x, x, y) = f(x, y, x) = f(y, x, x) = x;
\]
we say that $f$ is a minority operation if for all $x$ and $y$ in $A$,
\[
f(x, x, y) = f(x, y, x) = f(y, x, x) = y.
\]

We also say that a set $X$ of feasible evaluations admits a majority (respectively, minority) aggregator if it admits a ternary $(n = 3)$ aggregator every component of which is a majority (respectively, minority) operation. Clearly, $X$ admits a majority aggregator if and only if there is a ternary aggregator $F = (f_1, \ldots, f_m)$ for $X$ such that, for all $j = 1, \ldots, m$ and for all two-element subsets $B_j \subseteq X_j$, we have that $f_j | B_j = \text{maj}$ where
\[
\text{maj}(x, y, z) = \begin{cases} x & \text{if } x = y \text{ or } x = z, \\ y & \text{if } y = z. \end{cases}
\]

Similarly, $X$ admits a minority aggregator if and only if there is a ternary aggregator $F = (f_1, \ldots, f_m)$ for $X$ such that, for all $j = 1, \ldots, m$ and for all two-element subsets $B_j \subseteq X_j$, we have that $f_j | B_j = \oplus$, where
\[
\oplus(x, y, z) = \begin{cases} z & \text{if } x = y, \\ x & \text{if } y = z, \\ y & \text{if } x = z. \end{cases}
\]

In the Boolean framework, a set $X \subseteq \{0, 1\}^m$ admits a majority aggregator if and only if the majority operation maj on $\{0, 1\}^3$ is a polymorphism of $X$.

**Lemma 2.1.** [38, Lemma 3.1B] The majority operation maj on $\{0, 1\}^3$ is a polymorphism of a set $X \subseteq \{0, 1\}^m$ if and only if $X$ is a bijunctive logical relation, i.e., $X$ is the set of satisfying assignments of a 2CNF-formula.

A set $X \subseteq \{0, 1\}^m$ admits a minority aggregator if and only if the minority operation $\oplus$ on $\{0, 1\}^3$ is a polymorphism of $X$.

**Lemma 2.2.** [38, Lemma 3.1A] The minority operation $\oplus$ on $\{0, 1\}^3$ is a polymorphism of a set $X \subseteq \{0, 1\}^m$ if and only if $X$ is an affine logical relation, i.e., $X$ is the set of solutions of a system of linear equations over the two-element field.

Both these results are part of the proof in Schaefer’s Dichotomy Theorem for the Satisfiability Problem, in [38, Theorem 2.1]. Since aggregators are by definition conservative, we identify from now on the ternary majority and minority aggregators with maj and $\oplus$ respectively.

**Example 2.1.** Consider the sets $X_1$ and $X_2$ below.

(i) The set $X_1 = \{0, 1\}^3 \setminus \{(1, 0, 1), (0, 0, 1), (0, 0, 0)\}$ is bijunctive, since it is the set of satisfying assignments of the 2CNF-formula $(x \lor y) \land (y \lor \neg z)$.

(ii) The set $X_2 = \{(0, 0, 1), (0, 1, 0), (1, 0, 0), (1, 1, 1)\}$ is affine, since it is the set of solutions of the equation $x + y + z = 1$ over the two-element field.

(iii) Both sets $X_1$ and $X_2$ are possibility domains, since $X_1$ admits a majority aggregator and $X_2$ admits a minority aggregator.
Finally, a binary \((n = 2)\) aggregator is called a projection aggregator if all its components are projections and symmetric, if all its components are symmetric, i.e., \(f_j(x, y) = f_j(y, x)\), for all \(x, y \in X_j\) and for \(j = 1, \ldots, m\).

We now present two theorems that characterize possibility domains in the Boolean and the non-Boolean framework. They are the stepping stones towards showing that the following decision problem is solvable in polynomial time: given a set \(X\) of feasible evaluations, is \(X\) a possibility domain?

**Theorem A.** \([11]\) Let \(X \subseteq \{0,1\}^m\) be a set of feasible evaluations. The following two statements are equivalent.

1. \(X\) is a possibility domain.
2. \(X\) is affine or \(X\) is not totally blocked.

As mentioned in the Introduction, the existence of a binary non-dictatorial aggregator on \(X\) is closely related to the total blockedness of \(X\). We follow closely the notation and terminology used in \([12]\).

Let \(X\) be a set of feasible voting patterns. Given subsets \(B_j \subseteq X_j, j = 1, \ldots, m\), a sub box is the product \(B = \prod_{j=1}^m B_j\). It is called a 2-sub-box if \(|B_j| = 2\), for all \(j\). Elements of a box \(B\) that belong also to \(X\) will be called feasible evaluations within \(B\).

For a subset \(K \subseteq \{1, \ldots, m\}\) and a tuple \(x \in \prod_{j \in K} B_j\) is a feasible partial evaluation within \(B\) if there exists a feasible evaluation \(y\) within \(B\) that extends \(x\), i.e., \(x_j = y_j\), for all \(j \in K\). Otherwise, we say that \(x\) is an infeasible partial evaluation within \(B\). \(x\) is a B-Minimal Infeasible Partial Evaluation (B-MIPE) if (i) it is an infeasible partial evaluation within \(B\) and (ii) if for every \(j \in K\), there is a \(b_j \in B_j\) such that changing the \(j\)-th coordinate of \(x\) to \(b_j\) results into a feasible partial evaluation within \(B\).

We can now define a directed graph \(G_X\) as follows. The vertices of \(G_X\) are the pairs of distinct elements \(u, u'\) in \(X_j\), for all \(j = 1, \ldots, m\), denoted by \(uu'\). Two vertices \(uu'_k, vv'_l\) with \(k \neq l\) are connected by a directed edge from \(uu'_k\) to \(vv'_l\) if there exists a 2-sub-box \(B = \prod_{j=1}^m B_j\), a set \(K \subseteq \{1, \ldots, m\}\), and a B-MIPE \(x = (x_j)_{j \in K}\) such that \(k, l \in K\) and \(B_k = \{u, u'\}\) and \(B_l = \{v, v'\}\) and \(x_k = u\) and \(x_l = v'\).

**Definition 1.** \([12]\) We say that \(X\) is totally blocked if the graph \(G_X\) is strongly connected, i.e., every two distinct vertices \(uu'_k, vv'_l\) are connected by a directed path (this must hold even if \(k = l\)).

**Theorem B.** \([24]\) Let \(X\) be a set of feasible evaluations. The following two statements are equivalent.

1. \(X\) is totally blocked.
2. \(X\) admits no binary non-dictatorial aggregator.

In the Boolean framework, Theorem \([11]\) can be obtained from Theorem \([A]\) above and from \([11]\) Claim 3.6]. So by applying once more Theorem \([A]\) we get the following result.

**Corollary 2.1.** Implicit in \([11]\) Let \(X \subseteq \{0,1\}^m\) be a set of feasible evaluations. The following two statements are equivalent.

1. \(X\) is a possibility domain.
2. \(X\) is affine or \(X\) admits a binary non-dictatorial aggregator.
In the non-Boolean case, Kirousis et al. showed that:

**Theorem C.** [24, Theorem 3.1] Let $X$ be a set of feasible evaluations. The following two statements are equivalent.

1. $X$ is a possibility domain.
2. $X$ admits a binary non-dictatorial aggregator, or a majority aggregator, or a minority aggregator.

We illustrate the two preceding theorems with several examples.

**Example 2.2.** Let $X_3 = \{(1,0,0),(0,1,0),(0,0,1)\} \subseteq \{0,1\}^3$ be the set of all Boolean triples that contain exactly one 1. By Theorems A and B, the set $X_3$ is an impossibility domain, since it is not affine $((1,0,0),(0,1,0),(0,0,1)) \notin X_3$ and it does not have a binary non-dictatorial aggregator. For the latter, one has to check each of the 62 possible 3-tuples of conservative binary functions over $\{0,1\}$, which is a fairly tedious but straightforward task.

Before proceeding with the next example, let us state a straightforward result that we will need in what follows.

**Lemma 2.3.** Let $Y \subseteq A^l$, $Z \subseteq A^{m-l}$ and assume $G = (g_1,\ldots,g_l)$ and $H = (h_1,\ldots,h_{m-l})$ are $n$-ary aggregators of $Y$ and $Z$ respectively. Define $X \subseteq A^m$ as the Cartesian product of $Y$ and $Z$:

$$X := Y \times Z := \{(x_1,\ldots,x_l,x_{l+1},\ldots,x_m) \mid (x_1,\ldots,x_l) \in Y \text{ and } (x_{l+1},\ldots,x_m) \in Z\}.$$

Then, the $m$-tuple $F = (f_1,\ldots,f_m)$ of $n$-ary operations:

$$f_j = \begin{cases} g_j, & \text{if } j = 1,\ldots,l, \\ h_{j-l}, & \text{if } j = l+1,\ldots,m, \end{cases}$$

is an aggregator for $X$.

**Proof.** By the definition of $X$, for any $\bar{a}^i = (a^i_1,\ldots,a^i_m) \in X$, it holds that $(a^i_1,\ldots,a^i_l) \in Y$ and $(a^i_{l+1},\ldots,a^i_m) \in Z$, $i = 1,\ldots,n$. Now, since $G$ and $H$ are aggregators for $Y$ and $Z$, it holds that $G(a^1_1,\ldots,a^1_l) := (b_1,\ldots,b_l) \in Y$ and $H(a^1_{l+1},\ldots,a^1_m) := (b_{l+1},\ldots,b_m) \in Z$. Thus, again by the definition of $X$, $F(\bar{a}^1,\ldots,\bar{a}^n) = (b_1,\ldots,b_m) \in X$. □

**Example 2.3.** The following two sets $X_4$ and $X_5$ are possibility domains. For $X_4$, we show that this happens using three agents (thus the non-dictatorial aggregator attesting to that is ternary) and, for $X_5$, with two (and thus we find a binary non-dictatorial aggregator).

1. Let $X_4 = \{(0,1,2),(1,2,0),(2,0,1),(0,0,0)\}$. This set has been studied in [11, Example 4]. Let $F = (f_1,f_2,f_3)$ be such that, for each $j = 1,2,3$:

$$f_j(x,y,z) = \begin{cases} \text{maj}(x,y,z) & \text{if } |\{x,y,z\}| \leq 2, \\ 0 & \text{else}. \end{cases}$$

Clearly, $F$ is a majority operation. To see that $F$ is an aggregator for $X_4$, we need to check that $F(a,b,c) \in X_4$, only when $a,b,c$ are pairwise distinct vectors of $X_4$. In this case, $F(a,b,c) = (0,0,0) \in X_4$, since the input of each $f_j$ contains either two zeros or three pairwise distinct elements.
(ii) Let \( X_5 = X_1 \times X_3 \), where \( X_3 \) is as in Example 22. It is straightforward to check that \((p_1^2, p_2^2, p_3^2, p_4^2, p_5^2)\) is a non-dictatorial aggregator for \( X_5 \). In fact, a stronger fact holds: if \( Y \) and \( Z \) are arbitrary sets, then their Cartesian product \( Y \times Z \) is a possibility domain, since it admits non-dictatorial aggregators of any arity \( n \geq 2 \), defined as the \( d \)-th projection \( p_d^Y \) on coordinates from \( Y \) and as the \( d' \)-th projection \( p_d^Z \) on coordinates from \( Z \), where \( 1 \leq d, d' \leq n \) and \( d \neq d' \).

2.2. Uniform Possibility Domains. Let \( F = (f_1, \ldots, f_m) \) be an \( n \)-ary aggregator for \( X \). We say that \( F \) is a uniform non-dictatorial aggregator for \( X \) (of arity \( n \)) if, for all \( j \in \{1, \ldots, m\} \) and for every two-element subset \( B_j \subseteq X_j \), it holds that:

\[
f_j |_{B_j} \neq p_d^n, \text{ for all } d \in \{1, \ldots, n\}.
\]

We say that a set \( X \) is a uniform possibility domain if it admits a uniform non-dictatorial aggregator.

In the non-Boolean framework, uniform non-dictatorial aggregators were introduced by Kirousis et al. [24]. In the Boolean framework, this notion corresponds to locally non-dictatorial aggregators, which were introduced by Nehring and Puppe [35]. Following their terminology, we say that a uniform possibility domain in the Boolean framework is a local possibility domain.

The aforementioned sets \( X_1 \), \( X_2 \) and \( X_4 \) are uniform possibility domains, as \( X_1 \) and \( X_4 \) admit a majority aggregator, while \( X_2 \) admits a minority aggregator. Clearly, if \( X \) is a uniform possibility domain, then \( X \) is also a possibility domain. The converse, however, is not true. Indeed, suppose that \( X \) is a Cartesian product \( X = Y \times Z \), where \( Y \subseteq A^l \) and \( Z \subseteq A^{m-l} \), with \( 1 \leq l < m \). If \( Y \) or \( Z \) is an impossibility domain, then \( X \) is not a uniform possibility domain, although it is a possibility domain, since, as seen earlier, every Cartesian product of two sets is a possibility domain. It is also clear that if \( Y \) and \( Z \) are uniform possibility domains, then so is their Cartesian product \( Y \times Z \). In particular, the Cartesian product \( X_1 \times X_2 \) is a uniform possibility domain.

The next result characterizes uniform possibility domains. It is the stepping stone towards showing that the following decision problem is solvable in polynomial time: given a set \( X \) of feasible evaluations, is \( X \) a uniform possibility domain? We first need to define some operators. We say that \( f : A^n \rightarrow A \) is a weak near-unanimity operation \((\text{WNU})\) (see [28]) if, for all \( x, y \in A \), we have that

\[
f(y, x, x, \ldots, x) = f(x, y, x, \ldots, x) = \ldots = f(x, x, x, \ldots, y).
\]

In particular, a ternary weak near-unanimity operation is a function \( f : A^3 \rightarrow A \) such that for all \( x, y \in A \), we have that \( f(y, x, x) = f(x, y, x) = f(x, x, y) \). Thus, the notion of a ternary weak near-unanimity operation is a common generalization of the notions of a majority operation and a minority operation.

As with the majority/minority aggregators, we say that \( X \) admits a ternary weak near-unanimity aggregator \( F = (f_1, \ldots, f_m) \), if it admits a ternary aggregator every component of which is a weak near-unanimity operation, i.e., for all \( j = 1, \ldots, m \) and for all \( x, y \in X_j \), we have that \( f_j(y, x, x) = f_j(x, y, x) = f_j(x, x, y) \).

Finally, consider the Boolean operations \( \land, \lor : \{0, 1\}^2 \rightarrow \{0, 1\} \), defined as:

\[
\land(x, y) = \begin{cases} 
0 & \text{if } x = 0 \text{ or } y = 0, \\
1 & \text{else}
\end{cases}
\]

\[
\lor(x, y) = \begin{cases} 
1 & \text{if } x = 1 \text{ or } y = 1, \\
0 & \text{else}
\end{cases}
\]
and

\[ \forall(x, y) = \begin{cases} 
1 & \text{if } x = 1 \text{ or } y = 1, \\
0 & \text{else}. 
\end{cases} \]

For any \( x, y, z \in \{0, 1\} \), we define the ternary operations \( \wedge^{(3)} \) and \( \vee^{(3)} \) as follows:

\[ \wedge^{(3)}(x, y, z) = \wedge(\wedge(x, y), z) \quad \text{and} \quad \vee^{(3)}(x, y, z) = \vee(\vee(x, y), z). \]

From now on, to make notation easier, we arbitrarily identify any binary subset \( B \subseteq A \) with \( \{0, 1\} \), in order for the two symmetric operators \( \wedge, \vee \) to have meaning on its elements, without needing to assume each time a different ordering for each such \( B \).

**Theorem D.** [24, Theorem 5.5] Let \( X \) be a set of feasible evaluations. The following three statements are equivalent.

1. \( X \) is a uniform possibility domain.
2. \( X \) admits a ternary aggregator \( F = (f_1, \ldots, f_m) \) such that, for all \( j \in \{1, \ldots, m\} \) and for all subsets \( B_j \subseteq X_j \) of size 2, it holds that \( f_j|_{B_j} \in \{\wedge^{(3)}, \vee^{(3)}, \text{maj}, \oplus\} \).
3. \( X \) admits a ternary weak near-unanimity aggregator.

2.3. Computational Complexity. We end this section by briefly discussing the polynomial hierarchy (PH), which consists of a family of complexity classes that contain \( \text{NP} \) and \( \text{coNP} \), and are, in turn, contained in \( \text{PSPACE} \), the class of all decision problems solvable by algorithms that use a polynomial amount of space.

The complexity classes in the polynomial hierarchy were originally defined via oracles. An algorithm with access to an oracle \( O \) is an algorithm that can, in one step, obtain a yes/no answer for any instance of the decision problem \( O \). For example, an algorithm with access to a \( \text{SAT} \) oracle, can, in one step, learn if a propositional formula that has come up in its execution, is satisfiable or not. Note that since \( \text{SAT} \) is \( \text{NP} \)-complete, this gives the additional power to the algorithm of deciding any problem in \( \text{NP} \) in polynomial time. Given two complexity classes \( A \) and \( B \), the class of problems that can be decided by an algorithm in \( A \), with oracle access to the class \( B \) (i.e., with access to some complete problem of \( B \)), is denoted by \( A^B \). In this way, the complexity classes of the \( \text{PH} \) are \( \Sigma_k^P, \Pi_k^P \) and \( \Delta_k^P \), \( k \in \mathbb{N} \), which are recursively defined as follows:

- \( \Sigma_0^P = \Delta_0^P = \Pi_0^P = \text{P} \) and
- \( \Sigma_{k+1}^P \) is \( \text{NP} \) with oracle \( \Sigma_k^P \), \( \Pi_{k+1}^P \) is \( \text{coNP} \) with oracle \( \Sigma_k^P \) and \( \Delta_{k+1}^P \) is \( \text{P} \) with oracle \( \Sigma_k^P \), \( k \in \mathbb{N} \).

It is known that

\[ \Sigma_k^P \cup \Pi_k^P \subseteq \Delta_{k+1}^P \subseteq \Sigma_{k+1}^P \cap \Pi_{k+1}^P, \quad \forall k \in \mathbb{N}. \]

Furthermore, if for some \( k \in \mathbb{N} \), we have \( \Sigma_k^P = \Pi_k^P \), then \( \text{PH} \) collapses to that level, in the sense that \( \Pi_l^P = \Pi_k^P \), for all \( l \geq k \). For example, if \( \text{NP} = \text{coNP} \), then \( \Sigma_k^P = \Pi_k^P = \text{NP} \), for all \( k \geq 1 \). Every level of \( \text{PH} \) contains complete problems that are generalizations of \( \text{SAT} \). For example, \( \Sigma_k^{\text{SAT}} \) is complete for \( \Sigma_k^P \), where \( \Sigma^k\text{-SAT} \) is the following decision problem: given an expression of the form \( \exists x_1 \forall x_2 \ldots Q x_k \varphi(x_1, x_2, \ldots, x_k) \), where \( \varphi \) is a Boolean formula, is this expression true when the quantifiers vary over the set \( \{0, 1\} \)? (Here, \( Q = \exists \) if \( k \) is odd, while \( Q = \forall \) if \( k \) is even.)
For a more in depth discussion of the polynomial hierarchy, we refer the interested reader to Stockmeyer [40]. Finally, recall that NP and coNP can be defined via certificates:

\[ \text{NP} = \{ x \in \{0,1\}^* \mid \exists w \in \{0,1\}^{p(|x|)} : \langle x, w \rangle \in P \} , \]

\[ \text{coNP} = \{ x \in \{0,1\}^* \mid \forall w \in \{0,1\}^{p(|x|)} : \langle x, w \rangle \in P \} . \]

Under this notation, \( w \) is the certificate, i.e., a candidate solution for the instance \( x \), whose validity can be checked in polynomial time. Following this, we obtain an alternative description of the polynomial hierarchy via certificates:

\[ \Sigma^p_{k+1} = \exists \Pi^p_k = \{ x \in \{0,1\}^* \mid \exists w \in \{0,1\}^{p(|x|)} : \langle x, w \rangle \in \Pi^p_k \} , \]

\[ \Pi^p_{k+1} = \forall \Sigma^p_k = \{ x \in \{0,1\}^* \mid \forall w \in \{0,1\}^{p(|x|)} : \langle x, w \rangle \in \Sigma^p_k \} , \]

where \( p(|x|) \) is polynomial in the size of \( |x| \). We will use both definitions of these complexity classes to derive our results.

3. Explicitly given Domains

In subsection \[3.1\], we present a polynomial-time algorithm for checking if \( X \) is a possibility domain. In subsection \[3.2\], we prove that this problem is also expressible in Transitive Closure Logic (TCL). Finally, in subsection \[3.3\] we provide a polynomial-time algorithm for checking if a domain \( X \) is a uniform possibility domain.

3.1. Tractability of Possibility Domains. Theorems \[A\] and \[C\] provide necessary and sufficient conditions for a set \( X \) to be a possibility domain in the Boolean framework and in the non-Boolean framework, respectively. Admitting a binary non-dictatorial aggregator is a condition that appears in both of these characterizations. Our first result asserts that this condition can be checked in polynomial time.

**Theorem 3.1.** There is a polynomial-time algorithm for solving the following problem: given a set \( X \) of feasible evaluations, determine whether or not \( X \) admits a binary non-dictatorial aggregator and, if it does, produce one.

We first show that the existence of a binary non-dictatorial aggregator on \( X \) is tightly related to connectivity properties of a certain directed graph \( H_X \) defined next. If \( X \subseteq A^m \) is a set of feasible evaluations, then \( H_X \) is the following directed graph:

- The vertices of \( H_X \) are the pairs of distinct elements \( u, u' \in X_j \), for \( j \in \{1, \ldots, m\} \). Each such vertex will usually be denoted by \( uu'_j \). When the coordinate \( j \) is understood from the context, we will often be dropping the subscript \( j \), thus denoting such a vertex by \( uu' \).

- Two vertices \( uu'_j \) and \( vv'_l \), where \( k \neq l \), are connected by a directed edge from \( uu'_j \) to \( vv'_l \), denoted by \( uu'_j \rightarrow vv'_l \), if there are a total evaluation \( z \in X \) that extends the partial evaluation \( (u_k, v_l) \) and a total evaluation \( z' \in X \) that extends the partial evaluation \( (u'_k, v'_l) \), such that there is no total evaluation \( y \in X \) that extends \( (u_k, v'_l) \), and has the property that \( y_i = z_i \) or \( y_i = z'_i \), for every \( i \in \{1, \ldots, m\} \).
For vertices $u u_k'$, $v v_l'$, corresponding to issues $k, l$ (that need not be distinct), we write $u u_k' \to v v_l'$ to denote the existence of a directed path from $u u_k'$ to $v v_l'$. Note that if $u u_k' \to v v_l'$, then $v v_l' \to u u_k'$, since we require for the same partial vectors to be extendable.

In the next example, we describe explicitly the graph $H_X$ for several different sets $X$ of feasible voting patterns. Recall that a directed graph $G$ is strongly connected if for every pair of vertices $(u, v)$ of $G$, there is a (directed) path from $u$ to $v$.

Finally, consider the graph $G_X$ of Definition\(^\text{[1]}\) As will become apparent in the sequel, $H_X$ is strongly connected if and only if $G_X$ is. Nevertheless, $G_X$ can have more edges, since the infeasible partial evaluation $x$ can be changed in any $j \in K$ in order to become feasible.

**Example 3.1.** Recall the two Boolean domains $X_2 = \{(0, 0, 1), (0, 1, 0), (1, 0, 0), (1, 1, 1)\}$ and $X_3 = \{(0, 0, 1), (0, 1, 0), (1, 0, 0)\}$ of Examples [2.2] and [2.2]. Both $H_{X_2}$ and $H_{X_3}$ have six vertices, namely $01_j$ and $10_j$, for $j = 1, 2, 3$. In the figures below, we use undirected edges between two vertices $u u_k'$ and $v v_l'$ to denote the existence of both $u u_k' \to v v_l'$ and $v v_l' \to u u_k'$.

Consider $01_1$, $01_2$ of $H_{X_2}$. Since the partial vectors on the first two coordinates, $(0, 0)$ and $(1, 1)$, extend to $(0, 0, 1)$ and $(1, 1, 1)$, respectively, we need to check if there is a vector in $X_2$ extending $(0, 1)$, but whose third coordinate is $1$. Since $(0, 1, 1) \notin X_2$, we have that $H_{X_2}$ contains both edges $01_1 \to 01_2$ and $01_2 \to 01_1$. Now, since the partial vectors, again in the first two coordinates, $(0, 1)$ and $(1, 0)$ extend to $(0, 1, 0)$ and $(1, 0, 0)$, respectively, and since neither $(0, 0, 0)$ nor $(1, 1, 1)$ are in $X_2$, we have that $01_1 \leftrightarrow 10_2$. By the above and because of the symmetric structure of $X_2$, it is easy to see that every two vertices $u u_k'$ and $v v_l'$ of $H_{X_2}$ are connected if and only if $i \neq j$.

For $X_3$, observe that, since no partial vector containing two “1”’s, in any two positions, extends to an element of $X_3$, there are no edges between the vertices $01_i$, $01_j$ and $10_i$, $10_j$, for any $i, j \in \{1, 2, 3\}, i \neq j$. In the same way as with $H_{X_2}$, we get that $H_{X_3}$ is a cycle.

There are two observations to be made, concerning $H_{X_2}$ and $H_{X_3}$. First, they are both strongly connected graphs. Also, neither $X_2$ nor $X_3$ admit binary non-dictatorial aggregators. $X_2$ admits only a minority aggregator (the proof is left for the interested reader) and $X_3$ is an impossibility domain (as shown in Example [2.2]).
Finally, consider $X_6 := \{(0,1), (1,0)\}$. The graph $H_{X_6}$ has four vertices, 01$_1$, 10$_1$, 01$_2$ and 10$_2$, and it is easy to see that $H_{X_6}$ has only the following edges:

Observe that $X_6$ is not strongly connected (it is not even connected) and that, in contrast to the sets $X_2$ and $X_3$, the set $X_6$ admits two binary non-dictatorial aggregators, namely, $(\land, \lor)$ and $(\lor, \land)$. In Lemma 3.2, we establish a tight connection between strong connectedness and the existence of binary non-dictatorial aggregators.

We now state and prove two lemmas about the graph $H_X$.

Lemma 3.1. Assume that $F = (f_1, \ldots, f_m)$ is a binary aggregator on $X$.

1. If $u_k \rightarrow v_l$ and $f_k(u, u') = u$, then $f_l(v, v') = v$.
2. If $u_k \rightarrow v_l$ and $f_k(u, u') = u$, then $f_l(v, v') = v$.

Proof The first part of the lemma follows from the definitions and the fact that $F$ is conservative. Indeed, if $u_k \rightarrow v_l$, then there are a total valuation $z = (z_1, \ldots, z_m) \in X$ that extends $(u_k, v_l)$ (i.e., $z_k = u$ and $z_l = v$) and a total valuation $z' = (z'_1, \ldots, z'_m) \in X$ that extends $(u'_k, v'_l)$ (i.e., $z'_k = u'$ and $z'_l = v'$), such that there is no total evaluation in $X$ that extends $(u_k, v_l)$ and agrees with $z$ or with $z'$ on every coordinate. Consider the total evaluation $(f_1(z_1, z'_1), \ldots, f_m(z_m, z'_m))$, which is in $X$ because $F$ is an aggregator on $X$. Since each $f_j$ is conservative, we must have that $f_j(z_j, z'_j) \in \{z_j, z'_j\}$, for every $j$, hence $f_j(z_l, z'_l) = f_l(v, v') \in \{v, v'\}$. Consequently, if $f_k(u, u') = u$, then we must have $f_l(v, v') = v$, else $(f_1(z_1, z'_1), \ldots, f_m(z_m, z'_m))$ extends $(u_k, v'_l)$ and agrees with $z$ or with $z'$ on every coordinate. The second part of the lemma easily follows from the first part by induction. \qed

Lemma 3.2. $X$ admits a binary non-dictatorial aggregator if and only if the directed graph $H_X$ is not strongly connected.

Before delving into the proof, consider the graphs of Example 3.1. Using the fact that the graphs $H_{X_2}$ and $H_{X_3}$ are strongly connected and also using the second item of Lemma 3.1, it is easy to see that $X_2$ and $X_3$ admit no binary non-dictatorial aggregator; indeed, let $F = (f_1, f_2, f_3)$ be a binary aggregator of either of these two sets and suppose that $f_1(0,1) = 0$. Since in both graphs $H_{X_2}$ and $H_{X_3}$, there are paths from 01$_1$ to every other vertex, it follows that $f_j = pr^j_2$, $j = 1, 2, 3$. If $f_1(0,1) = 1$, we get that $f_j = pr^j_2$, $j = 1, 2, 3$, in the same way.

In contrast, consider $H_{X_6}$ and let $G = (g_1, g_2)$ be a pair of binary functions with $g_1(0,1) = 0$. For $G$ to be an aggregator, Lemma 3.1 forces us to set $g_2(1,0) = 1$. But now, by setting $g_1(1,0) = 0$, and thus $g_2(0,1) = 1$, we get that $(g_1, g_2) = (\land, \lor)$ is a non-dictatorial binary aggregator for $X_6$.

Proof of Lemma 3.2 We first show that if $X$ admits a binary non-dictatorial aggregator, then $H_X$ is not strongly connected. In the contrapositive form, we show
that if $H_X$ is strongly connected, then $X$ admits no binary non-dictatorial aggregator. This is an easy consequence of the preceding Lemma 3.1. Indeed, assume that $H_X$ is strongly connected and let $F = (f_1, \ldots, f_m)$ be a binary aggregator on $X$. Take two distinct elements $x$ and $x'$ of $X_1$. Since $F$ is conservative, we have that $f_1(x, x') \in \{x, x'\}$. Assume first that $f_1(x, x') = x$. We claim that $f_j = \text{pr}_1^2$, for every $j \in \{1, \ldots, m\}$. To see this, let $y$ and $y'$ be two distinct elements of $X_j$, for some $j \in \{1, \ldots, m\}$. Since $H_X$ is strongly connected, we have that $xx'_1 \rightarrow y y'_1$. Since also $f_1(x, x') = x$, Lemma 3.1 implies that $f_j(y, y') = y = \text{pr}_1^2(y, y')$ and so $f_j = \text{pr}_1^2$. Next, assume that $f_1(x, x') = x'$. We claim that $f_j = \text{pr}_2^2$, for every $j \in \{1, \ldots, m\}$. To see this, let $y$ and $y'$ be two distinct elements of $X_j$, for some $j \in \{1, \ldots, m\}$. Since $H_X$ is strongly connected, we have that $yy'_1 \rightarrow xx'_1$, hence, if $f_j(y, y') = y$, then, Lemma 3.1 implies that $f_1(x, x') = x$, which is a contradiction because $x \neq x'$. Thus, $f_j(y, y') = y'$ and so $f_j = \text{pr}_2^2$.

For the converse, assume that $H_X$ is not strongly connected and let $uu'_k, vv'_l$ be two vertices of $H_X$ such that there is no path from $uu'_k$ to $vv'_l$ in $H_X$, i.e., it is not true that $uu'_k \rightarrow vv'_l$. Let $V_1, V_2$ be a partition of the vertex set such that $uu'_k \in V_1, vv'_l \in V_2$, and there is no edge from a vertex in $V_1$ to a vertex in $V_2$. We will now define a binary aggregator $F = (f_1, \ldots, f_m)$ and prove that it is non-dictatorial.

Given $z, z' \in X$, we set $f_j(z_j, z'_j) = z_j$ if $zz'_j \in V_1$, and we set $f_j(z_j, z'_j) = z'_j$ if $zz'_j \in V_2$, for $j \in \{1, \ldots, m\}$. Since $uu'_k \in V_1$, we have that $f_k \neq \text{pr}_3^2$; similarly, since $vv'_l \in V_2$, we have that $f_l \neq \text{pr}_2^2$. Consequently, $F$ is not a dictatorial function on $X$. Thus, what remains to be proved is that if $z, z' \in X$, then $F(z, z') \in X$. For this, we will show that if $F(z, z') \notin X$, then there is an edge from an element of $V_1$ to an element of $V_2$, which is a contradiction.

Assume that $q = F(z, z') \notin X$. Let $K$ be a minimal subset of $\{1, \ldots, m\}$ such that $q|_K$ cannot be extended to a total evaluation $w$ in $X$ that agrees with $z$ or with $z'$ on $\{1, \ldots, m\} \setminus K$ (i.e., if $j \in \{1, \ldots, m\} \setminus K$, then $w_j = z_j$ or $w_j = z'_j$). Since $z'$ is in $X$, it does not extend $q|_K$, hence there is a number $s \in K$ such that $q_s = f_s(z_s, z'_s) = z_s \neq z'_s$. It follows that the vertex $zz'_s$ is in $V_1$. Similarly, since $z$ is in $X$, it does not extend $q|_K$, hence there is a number $t \in K$ such that $q_t = f_t(z_t, z'_t) = z'_t \neq z_t$. It follows that the vertex $zz'_t$ is in $V_2$. Consequently, there is no edge from $zz'_t$ to $zz'_s$ in $H_X$. We will arrive at a contradiction by showing that $zz'_t \rightarrow zz'_s$, i.e., there is an edge $zz'_t$ to $zz'_s$ in $H_X$. Consider the set $K \setminus \{t\}$. By the minimality of $K$, there is a total evaluation $w$ in $X$ that extends $q|_K \setminus \{t\}$ and agrees with $z$ or with $z'$ outside $K \setminus \{t\}$. In particular, we have that $w_s = q_s = z_s$ and $w_t = z_t$. Similarly, by considering the set $K \setminus \{s\}$, we find that there is a total evaluation $w'$ in $X$ that extends $q|_K \setminus \{s\}$ and agrees with $z$ or with $z'$ outside $K \setminus \{s\}$. In particular, we have that $w'_s = z'_s$ and $w_t = q_t = z'_t$. Note that $w$ and $w'$ agree on $K \setminus \{s, t\}$. Since $q|_K$ does not extend to a total evaluation that agrees with $z$ or with $z'$ outside $K$, we conclude that there is no total evaluation $y$ in $X$ that extends $(z_s, z'_s)$ and agrees with $w$ or with $w'$ on every coordinate. Consequently, $zz'_t \rightarrow zz'_s$, thus we have arrived at a contradiction.

**Proof of Theorem 3.1** Given a set $X$ of feasible evaluations, the graph $H_X$ can be constructed in time bounded by a polynomial in the size $|X|$ of $X$ (in fact, in time $O(|X|^5)$). There are well-known polynomial-time algorithms for testing if a graph is strongly connected and, in case it is not, producing the strongly connected components (scc) of the graph; e.g., Kosaraju’s algorithm presented in [59] and [43].
Consequently, by Lemma 3.2 there is a polynomial-time algorithm for determining whether or not a given set \(X\) admits a binary non-dictatorial aggregator. Moreover, if \(X\) admits such an aggregator, then one can be constructed in polynomial-time from the strongly connected components of \(H_X\) via the construction in the proof of Lemma 3.2.

The next corollary follows from Theorem 3.1 and Theorem 3.2.

**Corollary 3.1.** There is a polynomial-time algorithm for the following decision problem: given a set \(X\) of feasible evaluations, is \(X\) totally blocked?

We now turn to the problem of detecting possibility domains in the non-Boolean framework.

**Theorem 3.2.** There is a polynomial-time algorithm for solving the following problem: given a set \(X\) of feasible evaluations, determine whether or not \(X\) is a possibility domain and, if it is, produce a binary non-dictatorial aggregator, or a ternary majority aggregator or a ternary minority aggregator for \(X\).

**Proof** It is straightforward to check that, by Theorem C and Theorem 3.1, it suffices to show that there is a polynomial-time algorithm that, given \(X\), detects whether or not \(X\) admits a majority aggregator or a minority aggregator, and, if it does, produces such an aggregator.

Let \(X\) be a set of feasible evaluations, where \(I = \{1, \ldots, m\}\) is the set of issues and \(A\) is the set of the position values. We define the disjoint union \(A\) of the set of position values as:

\[ A = \bigcup_{j=1}^m A = \bigcup_{j=1}^m \{(x, j) \mid x \in A\}. \]

We also set
\[ \tilde{X} = \{(x_1, 1), \ldots, (x_m, m) \mid (x_1, \ldots, x_m) \in X\} \subseteq A^m. \]

We will show that we can go back-and-forth between conservative majority or minority polymorphisms for \(\tilde{X}\) and majority or minority aggregators for \(X\).

Let \(f : A^n \to A\) be a conservative polymorphism for \(\tilde{X}\). We define the \(m\)-tuple \(F = (f_1, \ldots, f_m)\) of \(n\)-ary functions \(f_1, \ldots, f_m\) as follows: if \(x_1^j, \ldots, x_n^j \in X_j\), for \(j \in \{1, \ldots, m\}\), then we set \(f_j(x_1^j, \ldots, x_n^j) = y_j\), where \(y_j\) is such that \(f((x_1^j, \ldots, x_n^j, j)) = (y_j, j)\). Such a \(y_j\) exists and is one of the \(x_i^j\)'s because \(f\) is conservative, and hence \(f((x_1^j, \ldots, x_n^j, j)) \in \{(x_1^j, j), \ldots, (x_n^j, j)\}\). It is easy to see that \(F\) is an aggregator for \(X\). Moreover, in case \(n = 3\), if \(f\) is a majority or a minority operation on \(\tilde{X}\), then \(F\) is a majority or a minority aggregator on \(X\).

Next, let \(F = (f_1, \ldots, f_m)\) be a (ternary) majority or a minority aggregator for \(X\). We define a ternary function \(f : A^3 \to A\) as follows. Let \((x, j), (y, k), (z, l)\) be three elements of \(A\).

- If \(j = k = l\), then we set \(f((x, j), (y, k), (z, l)) = (f_j(x, y, z), j)\).
- If \(j, k, l\) are not all equal, then if at least two of \(x, j\), \(y, k\), \(z, l\) are equal to each other, we set
  \[ f((x, j), (y, k), (z, l)) = \begin{cases} f_j(x, y, z), & \text{if } F \text{ is a majority aggregator on } X; \\ \oplus((x, j), (y, k), (z, l)), & \text{if } F \text{ is a minority aggregator on } X; \end{cases} \]
- otherwise, we set \(f((x, j), (y, k), (z, l)) = (x, j)\). 

\[ 
\]
It is easy to see that if $F$ is a majority or a minority aggregator for $X$, then $f$ is a conservative majority or a conservative minority polymorphism on $X$. It follows that $X$ admits a majority or a minority aggregator if and only if $X$ is closed under a conservative majority or minority polymorphism. Bessiere et al. [2 Theorem 1] and Carbonnel [8 Theorem 1] design polynomial-time algorithms that detect if a given constraint language $\Gamma$ has a conservative majority or a conservative minority polymorphism, respectively, and, when it has, compute such a polymorphism. Here, we apply these results to $\Gamma = \{X\}$.

We end this subsection by showing that using the graph $H_X$, we can compute a binary aggregator for $X$ that has as many symmetric components as possible. This will allow us to obtain better complexity bounds in Section 4.

Given a domain $X \subseteq A^m$ and a binary aggregator $F = (f_1, \ldots, f_m)$ for $X$, we say that $F$ is a maximum symmetric aggregator for $X$ if, for every binary aggregator $G = (g_1, \ldots, g_m)$ for $X$, for every $j \in \{1, \ldots, m\}$ and for all binary $B_j \subseteq X_j$, if $g_j \rvert_{B_j}$ is symmetric, then so is $f_j \rvert_{B_j}$. Note that a maximum symmetric aggregator does not necessarily have any symmetric components, for example in case $X$ is an impossibility domain. Furthermore, if $F$ and $G$ are both maximum symmetric aggregators for $X$, then they necessarily have the same symmetric components.

**Lemma 3.3.** Every domain $X$ admits a maximum symmetric aggregator.

**Proof** Assume that there is no maximum symmetric aggregator for $X$. Then, there exist two indices $i, j \in \{1, \ldots, m\}$ and two binary subsets $B_i \subseteq X_i$, $B_j \subseteq X_j$, such that:

- there are two binary aggregators $F = (f_1, \ldots, f_m)$ and $G = (g_1, \ldots, g_m)$ such that $f_i \rvert_{B_i}$ and $g_j \rvert_{B_j}$ are symmetric and
- there is no binary aggregator $H = (h_1, \ldots, h_m)$ such that both $h_i \rvert_{B_i}$ and $h_j \rvert_{B_j}$ are symmetric.

Let $H = (h_1, \ldots, h_m)$ be the $m$-tuple of binary functions such that, for all $k \in \{1, \ldots, m\}$ and for all $x, y \in X_k$: $h_k(x, y) := g_k(f_k(x, y), f_k(y, x))$. That $H$ is an aggregator for $X$ follows easily from the fact that $F$ and $G$ are. Let also $B_i = \{a, b\}$ and $B_j = \{c, d\}$. Since $f_i \rvert_{B_i}$ is symmetric, $f_i(a, b) = f_i(b, a)$, thus:

$$h_i(a, b) = g_i(f_i(a, b), f_i(b, a)) = g_i(f_i(a, b), f_i(a, b)) = f_i(a, b).$$

It follows that $h_i \rvert_{B_i}$ is symmetric. Now, by the hypothesis, $f_j \rvert_{B_j}$ is not symmetric. Assume w.l.o.g. that $f_j \rvert_{B_j} = p x_1^2$. Thus, it holds that:

$$h_j(c, d) = g_i(f_i(c, d), f_i(d, c)) = g_i(c, d),$$

which means that $h_j \rvert_{B_j}$ is symmetric. Contradiction. \[\square\]

**Remark 1.** Note that in Lemma [3.3] we in fact show that given two binary aggregators $F$ and $G$ that are symmetric on some binary $B_i \subseteq X_i$ and $B_j \subseteq X_j$, then we can always construct a binary aggregator $H$ that is symmetric in both $B_i$ and $B_j$.

To proceed, we discuss a result concerning the structure of the graph $H_X$. We say that two SCC’s $S_p$ and $S_q$ of $H_X$ are related if there exists a $j \in \{1, \ldots, m\}$ and two distinct elements $u, u' \in X_j$, such that $uu'_j \in S_p$ and $u'uu_j \in S_q$.

**Lemma 3.4.** Let $X$ be a set of feasible voting patterns and assume that $S_p$, $S_q$ and $S_r$ are three pairwise distinct SCC’s of $H_X$. Then, $S_p$, $S_q$ and $S_r$ cannot be pairwise related.
Proof To obtain a contradiction, assume they are. Then, there exist (not necessarily distinct) indices \(i, j, k \in \{1, \ldots, m\}\) and pairwise distinct elements \(u, u' \in X_i, v, v' \in X_j, w, w' \in X_k\) such that \(uu_i' \to vv_j' \to ww_k' \in S_p\). Since \(uu_i' \to vv_j' \to vv_j' \to uu_i'\), it follows that \(v'v_j' \to uu_i'\) and \(uu_i' \to v'v_j'\). Thus, \(S_p\) and \(S_k\) form together an scc of \(H_X\). Contradiction. \(\Box\)

We are now ready to show that we can find a maximum symmetric aggregator for a domain \(X\), in polynomial time in its size.

**Corollary 3.2.** There is a polynomial-time algorithm for solving the following problem: given a set \(X\) of feasible evaluations, produce a maximum symmetric aggregator for \(X\).

Proof Construct the graph \(H_X\). For a set of vertices \(S\), let \(N^+(S)\) and \(N^-(S)\) be its extended outwards and inwards neighborhood respectively in \(H_X\). That is, \(N^+(S) = S \cup \{uu_i' | \exists vv_j' \in S: vv_j' \to uu_i'\}\) and \(N^-(S) = S \cup \{uu_i' | \exists vv_j' \in S: uu_i' \to vv_j'\}\).

We define the \(m\)-tuple of binary functions \(F = (f_1, \ldots, f_m)\) as follows. If \(H_X\) is strongly connected, set \(f_j = \text{pr}_j^2\) for all \(j \in \{1, \ldots, m\}\). Else, assume w.l.o.g. that \(H_X\) is connected. If it is not, we can deal with each connected component independently in the same way. Assume that \(S_1, \ldots, S_t\), \(t \geq 2\), are the scc’s of \(H_X\), in their topological order.

(1) For each \(uu_i' \in S_1\), set \(f_1(u, u') = u'\).

(2) Let \(S\) be the set of vertices of every scc of \(H_X\) that is related with \(S_1\). For each \(vv_j' \in N^+(S)\), set \(f_j(v, v') = v\).

(3) Let \(S'\) be the set of vertices of every scc of \(H_X\) that is related with an scc of \(S\). Note that due to Lemma 3.4 such an scc cannot be related with \(S_1\). For each \(ww_k' \in N^-(S)\), set \(f_j(w, w') = w'\).

Note that any remaining scc must be in another connected component. If this is the case, we proceed as above for each such connected component. Finally, to be formally correct, let \(f_j(a, b) = a\) for every \(j \in \{1, \ldots, m\}\) and \(a, b \in A\) such that either \(a\) or \(b \notin X_j\).

We have already shown that, given \(X\), \(H_X\) can be constructed in polynomial time in its size and its scc’s can also be computed in linear time to the size of \(H_X\). Steps 1 — 3 can easily be implemented by checking once every scc of \(H_X\). Thus, the overall process is clearly polynomial.

It remains to show that \(F = (f_1, \ldots, f_m)\) is indeed a maximum symmetric aggregator for \(X\). To obtain a contradiction, suppose it is not. Then, there exist a \(i \in \{1, \ldots, m\}\), a binary subset \(B_i \subseteq X_i\) and a binary aggregator \(G = (g_1, \ldots, g_m)\) for \(X\) such that \(f_i|_{B_i}\) is not symmetric, whereas \(g_i|_{B_i}\) is.

Assume that \(B_i = \{u, u'\}\). Since \(G\) is a binary aggregator for \(X\) and \(g_i|_{B_i}\) is symmetric, by Lemma 3.1 there are no paths \(uu_i' \to u'u_i'\) or \(u'u_i' \to uu_i'\) in \(H_X\). Consequently, there are two distinct scc’s of \(H_X\), say \(S_p\) and \(S_q\), such that \(uu_i' \in S_p\) and \(u'u_i' \in S_q\) and there are no paths connecting a vertex in \(S_p\) with a vertex in \(S_q\). Given the way we constructed \(F = (f_1, \ldots, f_m)\), the vertices of both these scc’s are either all in \(S\) or they are all in \(S'\). We show that in both cases, there exist two pairwise distinct scc’s of \(H_X\) that are pairwise related. This is a contradiction, by Lemma 3.4.

First, assume that the vertices of \(S_p\) and \(S_q\) are all in \(S\). The case where the vertices of \(S_p\) and \(S_q\) are all in \(S'\) is analogous. If both of them are related with
the procedure produces a maximum symmetric aggregator on finite graphs; this means that there is no formula connectivity over such a schema structure.

1 \leq |A| \leq m.

A direct implication of Corollary 3.2 that will be used later, is the following.

**Corollary 3.3.** There is a polynomial-time procedure that, given the graph $H_X$, the procedure produces a maximum symmetric aggregator $F$ for $X$.

### 3.2. Expressibility in Transitive Closure Logic

We now establish that Theorem 3.1 can be refined to show that testing whether $X$ admits a binary non-dictatorial aggregator can be expressed in Transitive Closure Logic. Before spelling out the technical details, we present a minimum amount of the necessary background from mathematical logic and descriptive complexity.

First-Order Logic, Least Fixed-Point Logic, and Transitive Closure Logic. First-order logic is a formalism for specifying properties of mathematical objects, such as graphs, trees, partial orders, and, more generally, relational structures. By definition, a relational schema is a tuple $R = (R_1, \ldots, R_m)$ of relational symbols $R_i$, $1 \leq i \leq m$, each of which has a specified natural number $r_i$ as its arity. A relational structure over such a schema $R$ is a tuple of the form $A = (A, R_1, \ldots, R_m)$, where $A$ is a set called the universe of $A$ and each $R_i$ is a relation on $A$ of arity $r_i$, $1 \leq i \leq m$.

For example, a graph is a relational structure of the form $(A, R, E)$, where $E$ is a binary relation on $V$. A finite relational structure is a relational structure with a finite set as its universe. A formula of first-order logic is an expression built from atomic formulas of the form $x_i = x_j$ and $R_k(x_1, \ldots, x_{r_k})$ using conjunctions, disjunctions, negations, universal, and existential quantification. The semantics of formulas of first-order logic are given by interpreting the quantifiers $\exists$ and $\forall$ as ranging over the universe of the relational structure at hand. For example, in the case of graphs, the first-order formula $\forall x \forall y (E(x, y) \lor \exists z (E(x, z) \land E(z, y))$ asserts that the graph has diameter at most 2. For the precise definition of the syntax and the semantics of first-order logic, we refer the reader to [19].

It is well known that first-order logic has rather limited expressive power on finite structures. In particular, there is no formula of first-order logic that expresses connectivity on finite graphs; this means that there is no formula $\psi$ of first-order logic such that a finite graph $G$ satisfies $\psi$ if and only if $G$ is connected. Moreover, the same holds true for other properties of finite graphs of algorithmic significance, such as acyclicity and 2-colorability; for details, see, e.g., [29]. Intuitively, the reason for these limitations of first-order logic on finite structures lacks a recursion mechanism.

Least Fixed-Point Logic (LFP) augments first-order logic with a recursion mechanism in the form of least fixed-points of positive first-order formulas. More formally, one considers first-order formulas of the form $\varphi(x_1, \ldots, x_n, S)$, where $\varphi(x_1, \ldots, x_n, S)$ is a first-order formula over a relational schema with an extra $n$-ary relation symbol $S$ such that every occurrence of $S$ is within an even number of negation symbols. Every such formula has a least fixed-point, that is, for every relational structure $A$, there is a smallest relation $S^*$ such that $S^* = \{(a_1, \ldots, a_n) \in A^n : A \models \varphi(a_1, \ldots, a_n, S^*)\}$. We use the notation $\varphi^\infty(x, y)$ to denote a new formula that expresses the least fixed-point of $\varphi(x_1, \ldots, x_n, S)$. For example, if $\varphi(x_1, x_2, S)$ is
the formula $E(x_1, x_2) \lor \exists z (E(x_1, z) \land S(z, x_2))$, then, for every graph $G = (V, E)$, the least fixed-point $\varphi^\infty(x_1, x_2)$ of this formula defines the transitive closure of the edge relation $E$. Consequently, the expression $\forall x_1 \forall x_2 \varphi^\infty(x_1, x_2)$ is a formula of least fixed-point logic LFP that expresses connectivity. For a different example, let $\psi(x, S)$ be the formula $\forall y (E(y, x) \rightarrow T(y))$, where $T$ is a unary relation symbol. It can be verified that, for every finite graph $G = (V, E)$, the least fixed-point $\psi^\infty(x)$ defines the set of all nodes $v$ in $V$ such that no path containing $v$ leads to a cycle. Consequently, the expression $\forall x \psi^\infty(x)$ is a formula of least fixed-point logic LFP that expresses acyclicity on finite graphs.

Transitive Closure Logic (TCL) is the fragment of LFP that allows for the formation of the transitive closure of first-order definable relations. Thus, if $\theta(x_1, \ldots, x_k, x_{k+1}, \ldots, x_{2k})$ is a first-order formula, then we can form in TCL the least fixed point of the formula:

$$\theta(x_1, \ldots, x_k, x_{k+1}, \ldots, x_{2k}) \lor \\
\exists z_1 \cdots \exists z_k (\theta(x_1, \ldots, x_k, z_1, \ldots, z_k) \land S(z_1, \ldots, z_k, x_{k+1}, \ldots, x_{2k}))$$

As regards their expressive power, it is known that FO $\subset$ TCL $\subset$ LFP on the class of all finite graphs. In other words, FO is strictly less expressive than TLC, while TLC is strictly less expressive than LFP on the class of all finite graphs. As regards connections to computational complexity, it is known FO is properly contained in LOGSPACE, TLC is properly contained in NLOGSPACE, and LFP is properly contained in PTIME on the class of all finite graphs.

The situation, however, changes if ordered finite graphs are considered, that is, finite structures of the form $G = (V, E, \leq)$, where $E$ is a binary relation on $V$ and $\leq$ is a total order on $V$ that can be used in LFP and in TCL formulas. In this setting, it is known that TCL = NLOGSPACE and that LFP = PTIME (the latter result is known as the Immerman-Vardi Theorem); thus, separating TLC from LFP on the class of all ordered graphs is equivalent to showing that NLOGSPACE is properly contained in PTIME, which is an outstanding open problem in computational complexity. Furthermore, similar results hold for the class of all finite structures and the class of all ordered finite structure over a relational schema containing at least one relation symbol of arity at least 2. These results have been established in the context of descriptive complexity theory, which studies the connections between computational complexity and expressibility in logics on finite structures. We refer the reader to the monographs [19, 29] for detailed information.

Binary Non-dictatorial Aggregators and Transitive Closure Logic. After the preceding digression into logic and complexity, we return to the question of when a domain $X$ of feasible evaluations admits a binary non-dictatorial aggregation.

We begin by first encoding a set $X$ of feasible evaluations by a suitable finite structure. To this effect, we consider a relational schema $R$ consisting of three unary relations $X'$, $I'$, $V'$, and one ternary relation $R'$. Intuitively, $X'$ will be interpreted by a set of feasible evaluations, $I'$ will be interpreted by the set of issues at hand, and $V'$ will be interpreted by the set of positions over all issues.

Given a set $X \subseteq A^m$ of feasible evaluations, we let $A(X) = (A, X, I, V)$ be the following finite $R$-structure:

- $A = X \cup I \cup V$, where $I = \{1, \ldots, m\}$ is the set of issues, and $V$ is the union of all positions over all issues.
- $R$ is the ternary relation consisting of all triples $(x, j, v)$ such that $x \in X$ and $v$ is the $j$-th coordinate of $x$, i.e., the position for issue $j$ in $x$. 

It is clear that $X$ can be identified with the finite structure $A(X)$. Conversely, if we are given a finite $\mathbb{R}$-structure $A$ in which $R \subseteq X \times I \times V$, then $X$ can be thought of as a set of feasible evaluations over the issues $I$.

**Lemma 3.5.** There is a first-order formula $\varphi(u, u', k, v, v', l)$ such that, for every set $X$ of feasible evaluations, we have that $\varphi(u, u', k, v, v', l)$ defines the edge relation of the directed graph $H_X$, when interpreted on the finite structure $A(X)$.

**Proof** Consider the following first-order formula $\varphi(u, u', k, v, v', l)$:

$$
\begin{align*}
\exists z \exists z' ((X'(z) \land X'(z')) \land R'(z, k, u) \land R'(z, l, v) \land R(z, k, u') \land R(z, l, v')) \\
\land \neg \exists y (X'(y) \land R'(y, k, u) \land R'(y, l, v') \\
\land \forall j \forall w (R'(y, j, w) \rightarrow (R'(z, j, w) \lor R'(z', j, w)))).
\end{align*}
$$

It is immediate from the definition of $H_X$ that the formula $\phi(u, u', k, v, v', l)$ defines indeed the edge relation of $H_X$. \hfill \Box

We now have all the concepts and tools needed to obtain the following result.

**Theorem 3.3.** The following problem is expressible in Transitive Closure Logic TCL: given a set $X$ of feasible evaluations (encoded as the finite structure $A(X)$), does $X$ admit a binary, non-dictatorial aggregator? Hence, this problem is also expressible in Least Fixed Point Logic LFP.

**Proof** The result follows immediately from Lemma 3.2, Lemma 3.5, and the definition of Transitive Closure Logic. \hfill \Box

As stated earlier, every property that can be expressed in TCL is in NLOGSPACE. Thus, the problem of detecting if $X$ admits a binary non-dictatorial aggregator is in NLOGSPACE. Note that membership of this problem in NLOGSPACE could also be inferred from Lemma 3.2 and the observation that the graph $H_X$ can be constructed in LOGSPACE. Lemma 3.5 strengthens this observation by showing that $H_X$ is actually definable in first-order logic, which is a small fragment of LOGSPACE.

Now, let $X \subseteq \{0, 1\}^n$. We prove the following result.

**Lemma 3.6.** Checking whether a domain $X \subseteq \{0, 1\}^n$ is affine can be done in LOGSPACE.

**Proof** Suppose we have a Turing Machine with a read-only tape containing the tuples of $X$. In the work tape, we store triples $(i_1, i_2, i_3)$ of integers in $\{1, \ldots, n\}$ in binary. This takes $O(\log n)$ space. The integer $i_j$ points to the $i_j$-th element of $X$. We want to examine if the sum modulo 2 of these three elements is also in $X$.

To do that, for each such triple, we examine all integers $i_4 \leq n$ one at a time. This adds another $\log n$ number of cells in the work tape. We then store all integers $j \leq m$ binary, one at a time, using another $\log m$ bits to the work tape.

Once we have $i_1, i_2, i_3, i_4$, and $j$ on the work tape, we check whether the entry $a_j^{i_4} = \oplus(a_j^{i_1}, a_j^{i_2}, a_j^{i_3})$. If it is, we go to the next $j$. If it is not, we go to the next $i_4$, and when we are done with the triple $(i_1, i_2, i_3)$, we go to the next such triple. If for every triple $(i_1, i_2, i_3)$, we find a suitable integer $i_4$, $X$ is affine. Else, it is not. \hfill \Box

By Corollary 2.1, Lemma 3.6 and the discussion following Theorem 3.3, we obtain the following result.
Theorem 3.4. The following problem is in NLOGSPACE: given a set $X \subseteq \{0,1\}^m$ of feasible evaluations in the Boolean framework, decide whether or not $X$ is a possibility domain.

3.3. Tractability of Uniform Possibility Domains. Recall that a constraint language is a finite set $\Gamma$ of relations of finite arities over a finite non-empty set $A$. The conservative constraint satisfaction problem for $\Gamma$, denoted by c-CSP($\Gamma$), is the constraint satisfaction problem for the constraint language $\mathcal{T}$ that consists of the relations in $\Gamma$ and, in addition, all unary relations on $A$. Intuitively, this amounts to the ability to arbitrarily restrict the domain of each variable in a given instance.

Bulatov \cite{Bulatov06} established a dichotomy theorem for the computational complexity of c-CSP($\Gamma$): if for every two-element subset $B$ of $A$, there is a conservative polymorphism $f$ of $\Gamma$ such that $f$ is binary and $f|_B \in \{\land, \lor\}$ or $f$ is ternary and $f|_B \in \{\text{maj}, \oplus\}$, then c-CSP($\Gamma$) is solvable in polynomial time; otherwise, c-CSP($\Gamma$) is NP-complete. Carbonnel showed that the boundary of the dichotomy for c-CSP($\Gamma$) can be checked in polynomial time.

Theorem E. \cite[Theorem 4]{Carbonnel10} There is a polynomial-time algorithm for the following problem: given a constraint language $\Gamma$ on a set $A$, determine whether or not for every two-element subset $B \subseteq A$, there is a conservative polymorphism $f$ of $\Gamma$ such that either $f$ is binary and $f|_B \in \{\land, \lor\}$ or $f$ is ternary and $f|_B \in \{\text{maj}, \oplus\}$. Moreover, if such a polymorphism exists, then the algorithm produces one in polynomial time.

The final results of this section is about the complexity of detecting uniform possibility domains.

Theorem 3.5. There is a polynomial-time algorithm for solving the following problem: given a set $X$ of feasible evaluations, determine whether or not $X$ is a uniform possibility domain and, if it is, produce a ternary weak near-unanimity aggregator for $X$.

In what follows, given a two-element set $B$, we will arbitrarily identify its elements with 0 and 1. Consider the functions $\land^3$ and $\lor^3$ on $\{0,1\}^3$, where $\land^3(x,y,z) := (\land(x,y),z)$ and $\lor^3(x,y,z) := (\lor(x,y),z)$. It is easy to see that the only ternary, conservative, weak near-unanimity functions on $\{0,1\}$ are $\land^3$, $\lor^3$, maj, and $\oplus$. We will also make use of the following lemma, which gives an alternative formulation of the boundary of the dichotomy for conservative constraint satisfaction.

Lemma 3.7. Let $\Gamma$ be a constraint language on set $A$. The following two statements are equivalent.

1. For every two-element subset $B \subseteq A$, there exists a conservative polymorphism $f$ of $\Gamma$ (which, in general, depends on $B$), such that $f$ is binary and $f|_B \in \{\land, \lor\}$ or $f$ is ternary and $f|_B \in \{\text{maj}, \oplus\}$.
2. $\Gamma$ has a ternary, conservative, weak near-unanimity polymorphism.

Proof (Sketch) (1 $\Rightarrow$ 2) Given a two-element subset $B \subseteq A$ and a binary conservative polymorphism $f$ of $\Gamma$ such that $f|_B \in \{\land, \lor\}$, define $f'$ to be the ternary operation such that $f'(x,y,z) = f(f(x,y),z)$, for all $x,y,z \in A$. It is easy to see that $f'$ is a conservative polymorphism of $\Gamma$ as well and also that $f'|_B \in \{\land^3, \lor^3\}$.
The hypothesis and the preceding argument imply that, for each two-element subset \( B \subseteq A \), there exists a ternary conservative polymorphism \( f \) of \( \Gamma \) (which, in general, depends on \( B \)) such that \( f|_B \in \{ \wedge(3), \lor(3), \text{maj}, \oplus \} \). For each two-element subset \( B \subseteq A \), select such a polymorphism and let \( f^1, \ldots, f^N \), \( N \geq 1 \), be an enumeration of all these polymorphisms. Clearly, the restriction of each \( f^i \) to its respective two element subset is a weak near-unanimity operation.

Consider the \( \lor \) operator that takes as input two ternary operations \( f,g : A^3 \to A \) and returns as output a ternary operation \( f \lor g \) defined by
\[
(f \lor g)(x,y,z) := f(g(x,y,z), g(y,z,x), g(z,x,y)).
\]
If \( f,g \) are conservative polymorphisms of \( \Gamma \), then so is \( f \lor g \). Also, if \( B \) is a two-element subset of \( A \) such that \( f|_B \) or \( g|_B \) is a weak near-unanimity operation, then so is \( (f \lor g)|_B \). Consider now the iterated diamond operation \( h \) with
\[
h := f^1 \lor (f^2 \lor (\ldots (f^{N-1} \lor f^N) \ldots)).
\]
By the preceding discussion, \( h \) is a conservative polymorphism such that \( h|_B \) is a weak near-unanimous operation for every two-element subset \( B \subseteq A \), hence \( h \) itself is a weak near-unanimity, conservative, ternary operation of \( \Gamma \).

(2 \( \Rightarrow \) 1) Let \( h \) be a ternary, conservative, weak near-unanimity polymorphism of \( \Gamma \). Thus, for every two-element subset \( B \subseteq A \), we have that \( h|_B \in \{ \wedge(3), \lor(3), \text{maj}, \oplus \} \).

If there is a two-element subset \( B \subseteq A \) such that \( h|_B \in \{ \wedge(3), \lor(3) \} \), then consider the binary function \( g \), which is defined as:
\[
g(x,y) := h(x,x,y) = h((pr_1^2(y,x), pr_2^2(x,y), pr_3^2(y,x))).
\]
Obviously, \( g \) is a binary conservative polymorphism of \( \Gamma \); moreover, for every two-element subset \( B \subseteq A \), if \( h|_B \in \{ \wedge(3), \lor(3) \} \), then \( g|_B \in \{ \wedge, \lor \} \).

For a detailed proof of Lemma 3.7, see [24, Theorem 5.5].

Proof of Theorem 3.5 By Theorem 3.2, a set \( X \) of feasible evaluations is a uniform possibility domain if and only if there is a ternary aggregator \( F = (f_1, \ldots, f_m) \) such that each \( f_j \) is a weak near-unanimity operation, i.e., for all \( j \in \{1, \ldots, m\} \) and for all \( x,y \in X \), we have that \( f_j(x,y,y) = f_j(y,y,x) = f_j(y,y,x) \). As in the proof of Theorem 3.2, we can go back-and-forth between \( X \) and the set \( \hat{X} \) and verify that \( X \) is a uniform possibility domain if and only if \( \hat{X} \) has a ternary, conservative, weak near-unanimity polymorphism. Theorem 3.2 and Lemma 3.7 then imply that the existence of such a polymorphism can be tested in polynomial time, and that such a polymorphism can be produced in polynomial time, if one exists.

In the Boolean case, we can prove the tractability of detecting locally non-dictatorial aggregators without using Theorem 3.5. This will allow us to obtain better complexity bounds in Section 4. In the Boolean case, Theorem 3.2 has been strengthened by Diaz et al.:

Corollary 3.4. [24, Corollary 4.1] A Boolean domain \( X \subseteq \{0,1\}^m \) is a local possibility domain if and only if it admits a ternary aggregator \( F = (f_1, \ldots, f_m) \) such that \( f_j \in \{ \wedge(3), \lor(3), \oplus \} \), for \( j = 1, \ldots, m \).

Thus, we can obtain the following algorithm in the Boolean case.

Corollary 3.5. There is a polynomial-time algorithm for solving the following problem: given a Boolean set \( X \subseteq \{0,1\}^m \) of feasible evaluations, determine whether
or not $X$ is a local possibility domain and, if it is, produce a ternary aggregator $F = (f_1, \ldots, f_m)$ for $X$ such that $f_j \in \{\land(3), \lor(3), \oplus\}$, $j = 1, \ldots, m$.

**Proof** Let $F = (f_1, \ldots, f_m)$ be the binary maximum symmetric aggregator obtained by Corollary 3.2 and let $I, J \subseteq \{1, \ldots, m\}$ such that $f_i = \land$ for all $i \in I$ and $f_j = \lor$ for all $j \in J$ (both $I$ and $J$ can be empty). We prove that $X$ is a local possibility domain if and only if it admits the ternary aggregator $G = (g_1, \ldots, g_m)$, where $g_i = \land(3)$ for all $i \in I$, $g_j = \lor(3)$ for all $j \in J$ and $g_k = \oplus$, for all $k \in \{1, \ldots, m\} \setminus (I \cup J)$. Since we can obtain $F$ in polynomial-time in the size of $X$ and since checking whether $G$ is an aggregator for $X$ can be done also in polynomial time, the procedure is clearly polynomial in the size of $X$.

That $X$ is a local possibility domain if it admits $G$ is self-evident. Assume now that $X$ is a local possibility domain. Let also $F^{(3)} = (f^{(3)}_1, \ldots, f^{(3)}_m)$ be the $m$-tuple of ternary functions, where

$$f^{(3)}_j(x, y, z) = f_j(f_j(x, y), z),$$

$j = 1, \ldots, m$. It is straightforward to check that (i) $F^{(3)}$ is an aggregator for $X$, (ii) $f^{(3)}_i = \land(3)$ for all $i \in I$, (iii) $f^{(3)}_j = \lor(3)$ for all $j \in J$ and (iv) $f^{(3)}_k \in \{pr^3_1, pr^3_3\}$ for all $k \in \{1, \ldots, m\} \setminus (I \cup J)$.

Now, since $X$ is a local possibility domain, by Corollary 3.2 $X$ admits a ternary aggregator $H = (h_1, \ldots, h_m)$, such that $h_j \in \{\land(3), \lor(3), \oplus\}$, $j = 1, \ldots, m$. If $H = G$, there is nothing to prove.

First, assume that there is some $k \notin I \cup J$, such that $h_k \in \{\land(3), \lor(3)\}$. Now, let $G' = (g'_1, \ldots, g'_m) := H \oslash F^{(3)}$ and $F' = (f'_1, \ldots, f'_m)$ be a binary $m$-tuple of functions such that:

$$f'_j(x, y) := g'(x, x, y), \text{ for all } x, y \in A.$$  

It holds that $G'$ is an aggregator for $X$ such that $g'_j \in \{\land(3), \lor(3)\}$, for all $j \in I \cup J \cup \{k\}$. Thus, $F'$ is a non-dictatorial aggregator and $f'_j$ is symmetric for all $j \in I \cup J \cup \{k\}$. Contradiction, since $F$ is a maximum symmetric aggregator and $f_k$ is not symmetric.

Finally, suppose that there is some $j \in I \cup J$ such that $h_k = \oplus$, for all $k \in (\{1, \ldots, m\} \setminus (I \cup J)) \cup \{j\}$. Then, $G = H \oslash F^{(3)}$ and thus is an aggregator for $X$.

4. Implicitly Given Domains

In Subsection 4.1 we describe the logic-based approach, where the domain $X$ is given implicitly via an integrity constraint or an agenda. In Subsections 4.2 and 4.3 we establish complexity bounds for checking whether a domain is a possibility domain or a local possibility domain in these two variants of the logic-based approach (recall that a local possibility domain is a uniform possibility domain in the Boolean framework). Finally, in Subsection 4.4 we extend these results to other types of non-dictatorial aggregation that have been used in the literature.

4.1. The Logic-based Approach. In this subsection, we present two ways that a set $X$ of feasible voting patterns can be given implicitly: as an integrity constraint and as an agenda. Both variants are in the Boolean framework and have been studied extensively in the literature.

Suppose that we have a propositional formula $\phi$ on $m$ variables $x_1, \ldots, x_m$. Each variable $x_j$ corresponds to the $j$-th issue, $j = 1, \ldots, m$, where the possible positions
are 0 and 1. Let $X_\phi := \text{Mod}(\phi)$ be the set consisting of all $m$-ary vectors of satisfying truth assignments of $\phi$. In this setting, we say that $\phi$ is an integrity constraint.

For the second variant, suppose that we have an agenda $\tilde{\phi} = (\phi_1, \ldots, \phi_m)$ of $m$ propositional formulas. For a formula $\psi$ and an $x \in \{0, 1\}$, let

$$\psi^x := \begin{cases} \psi & \text{if } x = 1, \\ \neg \psi & \text{if } x = 0. \end{cases}$$

Finally, let:

$$X_{\tilde{\phi}} := \left\{ \bar{x} = (x_1, \ldots, x_m) \in \{0, 1\}^m \mid \bigwedge_{j=1}^m \phi_j^x \text{ is satisfiable} \right\}.$$
integrity constraint \((x_1 \lor \neg x_1) \land \cdots \land (x_m \lor \neg x_m)\) and the agenda \((x_1, \ldots, x_m)\),
where \(x_1, \ldots, x_m\) are pairwise distinct variables. Both have domains equal to the
full Boolean domain \(\{0, 1\}^m\). Finally, Endriss et al. \cite{Endriss15} Proposition 9] show that,
unless the polynomial hierarchy collapses, we cannot describe any arbitrary agenda
by an integrity constraint of polynomial size to that of the agenda and that, given
an integrity constraint \(\phi\), the problem of finding an agenda \(\bar{\phi}\) such that \(X_{\bar{\phi}} = X_{\phi}\)
is NP-complete.

Here, we examine the computational complexity of checking if a domain \(X\) is a
(local) possibility domain in both the integrity constraint variant and the agenda
variant. In all that follows, we assume that the integrity constraints are defined on
at least three variables and agendas contain at least three propositional formulas,
since domains \(X \subseteq \{0, 1\}^m\) where \(m = 1\) or \(2\) are all possibility domains.

4.2. Integrity Constraints. Let \(\phi\) be an integrity constraint on \(m\) variables and
let \(X_{\phi} = \text{Mod}(\phi) \subseteq \{0, 1\}^m\). The following theorems provide upper and lower
bounds to the complexity of checking if \(X_{\phi}\) is a (local) possibility domain. For
the upper bounds, we work with oracles, using the definition of the graph \(H_X\) in
Section \ref{section:graph} and make use of the following straightforward fact.

Lemma 4.1. Let \(F = (f_1, \ldots, f_m)\) be an \(m\)-tuple of \(n\)-ary conservative and polynomial-
time computable functions. Deciding, on input \(\phi\), whether \(F\) is an aggregator for
\(X_{\phi}\) is in \(\Pi^P_1 = \text{coNP}\).

Proof. The result is immediate since the problem can be cast as follows:

for all \(m\)-tuples \(\bar{x}^1, \ldots, \bar{x}^n \in \{0, 1\}^m\), if all \(n\) satisfy \(\phi\), then so does
the \(m\)-tuple \(F(\bar{x}^1, \ldots, \bar{x}^n)\)

and since checking if a formula \(\phi\) is satisfied by a specific assignment can be done
in polynomial time. \(\square\)

A function \(f\) is polynomial-time computable if given its input \(\bar{x}\), we can compute
its output \(f(\bar{x})\) in polynomial time. For our purposes, it suffices that the functions
\(\land, \lor, \oplus, \land^{(3)}, \lor^{(3)}\) and \(\text{pr}_i^n\) are all polynomial-time computable, for all \(n \in \mathbb{N}\) and
\(i \in \{1, \ldots, n\}\).

In terms of lower bounds, we provide polynomial-time reductions from two \text{coNP}
-complete problems: the \emph{semantical independence} problem and the \emph{unsatisfiability}
problem for propositional formulas. The latter is the well known problem of
whether a formula has no satisfying assignments. The former asks whether a given
propositional formula is \emph{(semantically) dependent} to all its variables; that is, there
is no variable (or set of variables) such that whether an assignment of values satisfies
the given formula or not, does not depend on the values of the variable(s). For
a systematic overview of this problem and its variations, see \cite{Blass92} and \cite{Blass94}. In the
setting of agendas, this notion has been studied under the name \emph{agenda separability}
(see \cite{Endriss13}).

For domain \(X \subseteq \{0, 1\}^m\) and a nonempty subset \(I \subseteq \{1, \ldots, m\}\), we denote by
\(X_I\) the projection of \(X\) to \(I\), that is the set of all partial vectors with indices in \(I\)
that can be extended to elements of \(X\). Let also \(X_{\neg I} := X_{\{1, \ldots, m\} \setminus I}\) and \(X \approx Y\)
mean that we can obtain \(X\) by permuting the columns of \(Y\).

Definition 2. Let \(\phi(x_1, \ldots, x_m)\) be a propositional formula, where \(X := \text{Mod}(\phi)\)
and let \(V \subseteq \{x_1, \ldots, x_m\}\) be a subset of its variables. Let also \(i \in \{1, \ldots, m\}\). We
say that \(\phi\) is:
In our setting, an integrity constraint being independent from a variable $x_j$ means that issue $j$ does not contribute anything in the logical consistency restrictions imposed by the constraint. Lang et al. [26] showed that the problem of checking if a propositional formula depends on all its variables (is simplified variable-dependent in their terminology), is coNP-complete.

To make our reductions easier to follow, we work with the specific domain:

$$\text{Imp} := \{0, 1\}^3 \setminus \{(0, 0, 0), (1, 1, 1)\}.$$ 

Observe that Imp corresponds to a natural and well studied problem in both preference and judgment aggregation. Suppose that we have three alternatives $A$, $B$ and $C$, where issue 1 corresponds to deciding between $A$ and $B$, issue 2 corresponds to deciding between $B$ and $C$, and issue 3 corresponds to deciding between $C$ and $A$.

In that setting, we can assume that, in each issue, 1 denotes preferring the former option and 0 the latter. One can easily see now that Imp corresponds to the natural requirement of transitivity of preferences.

Consider now the following lemma, which is a version of Arrow’s impossibility result in Judgment Aggregation.

**Lemma 4.2.** Imp is an impossibility domain.

**Proof** By Corollary 2.1 we only need to check if Imp is affine, or if it admits a binary non-dictatorial aggregator. Easily,

$$\oplus((1, 0, 0), (0, 1, 0), (0, 0, 1)) = (0, 0, 0) \notin \text{Imp},$$

thus Imp is not affine.

On the other hand, let $F = (f_1, f_2, f_3)$ be a binary non-dictatorial triple of functions. There are $4^3 - 2 = 62$ cases for $F$. We arbitrarily choose to show three of them. The rest are left to the interested reader.

- If $f_1 = f_2 = \land$ and $f_3 = \lor$, then $F((1, 0, 0), (0, 1, 0)) = (0, 0, 0) \notin \text{Imp}.$
- If $f_1 = \land$, $f_2 = \lor$ and $f_3 = \text{pr}_{1}^{3}$, then $F((1, 0, 0), (0, 0, 1)) = (0, 0, 0) \notin \text{Imp}.$
- If $f_1 = \lor$, $f_2 = \text{pr}_{1}^{3}$ and $f_3 = \text{pr}_{2}^{3}$, then $F((0, 0, 1), (0, 1, 0)) = (0, 0, 0) \notin \text{Imp}.$

Thus, for $F$ to be an aggregator for Imp, it must hold that $f_1 = f_2 = f_3 = \text{pr}_{d}^{3}$, $d = 1, 2$ and, consequently Imp admits only dictatorial binary aggregators. 

Let $\psi$ be the propositional formula:

$$(1) \quad \psi(y_1, y_2, y_3) = (y_1 \lor y_2 \lor y_3) \land (\neg y_1 \lor \neg y_2 \lor \neg y_3).$$

Easily, Mod($\psi$) = Imp. We are now ready to obtain our results.

**Theorem 4.1.** Deciding, on input $\phi$, whether $X_\phi$ admits a non-dictatorial aggregator is (i) in $\Sigma_2^P \cap \Pi_2^P$ and (ii) coNP-hard.

**Proof** (ii) By Corollary 2.1 $X_\phi$ is a possibility domain if and only if it admits a binary non-dictatorial aggregator or it is affine. The problem of whether $X_\phi$ is affine is in $\Pi_2^P = \text{coNP}$ (and thus in $\Sigma_2^P \cap \Pi_2^P$ too), by Lemma 4.1 using $\oplus$ for the given $m$-tuple of functions (recall also Lemma 2.2).
For the problem of the existence of binary non-dictatorial aggregators for \( X_\phi \), we show separately that it is both in \( \Sigma^P_2 \) and in \( \Pi^P_2 \). For the former, note that there are only four conservative (equivalently Pareto) functions from \( \{0, 1\}^2 \to \{0, 1\} \), namely \( \text{pr}^T_1, \text{pr}^T_2, \land \) and \( \lor \). Therefore, there are \( 4^m - 2 \) tuples \( F = (f_1, \ldots, f_m) \), with \( f_j : \{0, 1\}^2 \to \{0, 1\} \), \( j = 1, \ldots, m \) of \( m \) conservative functions, where not all \( f_j \) are the same projection function. Such an \( m \)-tuple can be thought of as a binary \((2 \times 3)m\)-sequence, where each \( f_j \) is encoded by a sequence \((01a10b)\), \( a, b \in \{0, 1\} \), meaning that \( f_j(0, 1) = a \) and \( f_j(1, 0) = b \).

Let us call such \( F \) candidates for non-dictatorial aggregators. The question of deciding whether a given \( F \) is one of the \( 4^m - 2 \) candidates for non-dictatorial aggregators is easily in \( \mathsf{P} \). Also, the question of whether a given binary \( F \) is an aggregator for \( X_\phi \) is again in \( \Pi^P_2 \) by Lemma 4.1. Therefore the problem of whether \( X_\phi \) admits a binary non-dictatorial aggregator is in \( \Sigma^P_2 \) because it can be cast as:

There exists a \( F = (f_1, \ldots, f_m) \) such that \( F \) is a candidate for non-dictatorial aggregator and for all \( m \)-tuples \( x, y \in \{0, 1\}^m \), if both satisfy \( \phi \), then so does the \( m \)-tuple \( F(x, y) \).

To show that it is also in \( \Pi^P_2 \), recall that, by Lemma 3.2, the set \( X_\phi \) admits a binary non-dictatorial aggregator if and only if the graph \( H_\phi \) is not strongly connected. We will show that checking if \( H_\phi \) is strongly connected is in \( \Sigma^P_2 \), which means that checking if \( H_\phi \) is not strongly connected is in \( \Pi^P_2 \).

First note that the size of \( H_\phi \) is polynomial in the size of \( \phi \), since it has \( 2m \) nodes, where \( m \) is the number of variables of \( \phi \). Thus, it suffices to prove that testing whether two nodes of \( H_\phi \) are connected is in \( \mathsf{NP} \) with an oracle in \( \mathsf{coNP} \).

To test if two nodes are connected, we first obtain a path witnessing this. To verify it is indeed a path, we need to check if any two of its consecutive nodes, say \( uu'_s \) and \( vv'_t \), are connected by the edge \( uu'_s \to vv'_t \) in \( H_\phi \). To do that, we can again take the satisfying assignments \( z \) and \( z' \) of \( \phi \) that witness that \( uu'_s \to vv'_t \). Then, using the \( \mathsf{coNP} \) oracle, we need to check that there is no \( z'' \) that: (i) satisfies \( \phi \), (ii) extends \( w' \) and (iii) agrees on every coordinate either \( z \) or \( z' \).

(ii) Let \( \chi(x_1, \ldots, x_k) \) be a propositional formula on \( k \) variables. We construct, in polynomial time, a formula \( \phi \) such that \( \chi \) is independent from at least one of its variables if and only if \( X_\phi \) is a possibility domain. In all that follows, \( m = k + 3 \).

Let:

\[
\phi(x_1, \ldots, x_k, y_1, y_2, y_3) = \chi(x_1, \ldots, x_k) \oplus \psi(y_1, y_2, y_3),
\]

where: \( \{x_1, \ldots, x_k\} \) and \( \{y_1, y_2, y_3\} \) are disjoint sets of variables.

First, note that the length \( |\phi| \) of \( \phi \) is linear to that of \( \chi \), since \( |\phi| = |\chi| + 6 \). Thus the construction is polynomial.

By (1), it holds that:

\[
(2) \quad X_\phi = \left( \text{Mod}(\chi) \times \{(0, 0, 0), (1, 1, 1)\} \right) \cup \left( \text{Mod}(\neg\chi) \times \text{Imp} \right).
\]

**Claim 4.1.1.** \( \chi \) is independent from at least one of its variables if and only if \( X_\phi \) is a possibility domain.

**Proof of Claim:** We first consider the two extreme cases. If \( \chi \) is unsatisfiable or a tautology, then by (2) we have that:

\[
X_\phi = \{0, 1\}^k \times \text{Imp},
\]

or that

\[
X_\phi = \{0, 1\}^k \times \{(0, 0, 0), (1, 1, 1)\}
\]
respectively. In both cases, we have that \( \chi \) is independent from all its variables and \( X_{\phi} \) is a possibility domain, since it is a Cartesian product (recall Lemma 2.5).

Thus, we can assume that both \( \text{Mod}(\chi) \) and \( \text{Mod}(\neg \chi) \) are not empty. We proceed with a series of claims.

**Claim 4.1.2.** \( X_{\phi} \) is not affine.

*Proof of Claim:* Let \( a := (a_1, \ldots, a_k) \in \text{Mod}(\neg \chi) \). Then, \((\bar{a}, 0, 1, 1), (\bar{a}, 1, 0, 1), (\bar{a}, 1, 1, 0) \in X_{\phi} \) and:

\[
\mathcal{N}((\bar{a}, 0, 1, 1), (\bar{a}, 1, 0, 1), (\bar{a}, 1, 1, 0)) = (\bar{a}, 0, 0, 0) \notin X_{\phi}.
\]

Thus, \( X_{\phi} \) is not affine.

By Corollary 2.1 and Claim 4.1.2, \( X_{\phi} \) is a possibility domain if and only if it admits a binary non-dictatorial aggregator. The following claims show that such an aggregator must be in a restricted class.

**Claim 4.1.3.** Assume \( F = (f_1, \ldots, f_m) \) is a binary aggregator for \( X_{\phi} \). Then, \( f_{k+1} = f_{k+2} = f_{k+3} = \text{pr}_2^{d_1}, d \in \{1, 2\} \).

*Proof of Claim:* To obtain a contradiction, assume \((f_{k+1}, f_{k+2}, f_{k+3}) \neq (\text{pr}_2, \text{pr}_2, \text{pr}_3), d = 1, 2 \). By Lemma 4.2, \( \text{Imp} \) is an impossibility domain. Thus, there exist \( \bar{x}, \bar{y} \in \text{Imp} \) such that

\[
\bar{z} := (f_{k+1}, f_{k+2}, f_{k+3})(\bar{x}, \bar{y}) \in \{(0, 0, 0), (1, 1, 1)\}.
\]

Let \( a := (a_1, \ldots, a_k) \in \text{Mod}(\neg \chi) \). Then \((\bar{a}, \bar{x}), (\bar{a}, \bar{y}) \in X_{\phi} \), but:

\[
F((\bar{a}, \bar{x}), (\bar{a}, \bar{y})) = (\bar{a}, \bar{z}) \notin X_{\phi}.
\]

Thus, \( F \) is not an aggregator for \( X_{\phi} \). Contradiction.

The following claim states that \( F = (f_1, \ldots, f_k, f_{k+1}, f_{k+2}, f_{k+3}) \) cannot have its first \( k \) coordinates be projections to the same coordinate \( d \in \{1, 2\} \) and the last three be projections to the other. This can also be derived by \( \text{(2)} \), since \( X_{\phi} \) is not a Cartesian product. For a proof of this general and straightforward characterization, the interested reader is referred to \( \text{(9)} \). Here we opted to showcase the technique we follow throughout the rest of the proof.

**Claim 4.1.4.** Assume \( F = (f_1, \ldots, f_m) \) is a binary aggregator for \( X_{\phi} \). If \( f_{k+1} = f_{k+2} = f_{k+3} = \text{pr}_3^{d'}, d, d' \in \{1, 2\}, d \neq d' \).

*Proof of Claim:* We show the claim for \( d = 2 \) and \( d' = 1 \). The analogous arguments hold for the case where \( d = 1 \) and \( d' = 2 \).

To obtain a contradiction, assume that \( f_1 = \cdots = f_k = \text{pr}_1^2 \). Let \( a := (a_1, \ldots, a_k) \in \text{Mod}(\chi) \) and \( \bar{b} := (b_1, \ldots, b_k) \in \text{Mod}(\neg \chi) \). Then, \((\bar{a}, 0, 0, 0) \) and 

\[
F((\bar{a}, 0, 0, 0), (\bar{b}, 0, 0, 1)) = (\bar{a}, 0, 0, 1) \notin X_{\phi}.
\]

Thus, \( F \) is not an aggregator for \( X_{\phi} \). Contradiction.

**Claim 4.1.5.** Assume \( F = (f_1, \ldots, f_m) \) is a binary aggregator for \( X_{\phi} \). Then, there is at least one \( j \in \{1, \ldots, k\} \) such that \( f_j \) is not symmetric.
Proof of Claim: By Claim 4.1.3 for some $d \in \{1, 2\}$, $f_{k+1} = f_{k+2} = f_{k+3} = \text{pr}_d^2$. To obtain a contradiction, assume that $f_j$ is symmetric for all $j \in \{1, \ldots, k\}$. Assume also w.l.o.g. that $d = 2$. The analogous arguments work for $d = 1$.

Let $\bar{a} := (a_1, \ldots, a_k) \in \text{Mod}(\chi)$, $\bar{b} := (b_1, \ldots, b_k) \in \text{Mod}(\neg\chi)$ and 

$$(f_1, \ldots, f_k)(\bar{a}, \bar{b}) := \bar{c}.$$ 

Then, $(\bar{a}, 0, 0, 0)$ and $(\bar{b}, 0, 0, 1) \in X$. Since $F$ is an aggregator for $X_\phi$:

$$f((\bar{a}, 0, 0, 0), (\bar{b}, 0, 0, 1)) = (\bar{c}, 0, 0, 0) \in X_\phi,$$
$$f((\bar{b}, 0, 0, 1), (\bar{a}, 0, 0, 0)) = (\bar{c}, 0, 0, 1) \in X_\phi,$$

which, by (2), implies that $\bar{c} \in \text{Mod}(\chi) \cap \text{Mod}(\neg\chi)$. Contradiction.

The last claim deals with the case where we have both symmetric and non-symmetric components in $(f_1, \ldots, f_k)$. It completely outlines the class of binary aggregators available for $X_\phi$. Notationally, if $\bar{a} \in \{0, 1\}^m$ and $I \subseteq \{1, \ldots, m\}$, $\bar{a}_I$ denotes the projection of $\bar{a}$ to the coordinates in $I$.

Claim 4.1.6. Assume $F = (f_1, \ldots, f_m)$ is a binary aggregator for $X_\phi$. Then, there exists a non-empty subset $J \subseteq \{1, \ldots, k\}$ such that $f_j = \text{pr}_d^2$ for all $j \in J \cup \{k+1, k+2, k+3\}$, $d = 1, 2$.

Proof of Claim: By Claim 4.1.3 for some $d \in \{1, 2\}$, $f_{k+1} = f_{k+2} = f_{k+3} = \text{pr}_d^2$. To obtain a contradiction, assume that $f_j \neq \text{pr}_d^2$, for all $j \in \{1, \ldots, k\}$. Assume also w.l.o.g. that $d = 2$. The analogous arguments work for $d = 1$.

By Claims 4.1.4 and 4.1.5, there exists a partition $(I, J)$ of $\{1, \ldots, k\}$, such that $f_i$ is symmetric for all $i \in I$ and $f_j = \text{pr}_d^2$ for all $j \in J$. To make things easier to follow, assume w.l.o.g. that there exists an $s \in \{1, \ldots, k-1\}$ such that $I = \{1, \ldots, s\}$ and $J = \{s+1, \ldots, k\}$. Let $\bar{a} := (a_1, \ldots, a_k) \in \text{Mod}(\chi)$, $\bar{b} := (b_1, \ldots, b_k) \in \text{Mod}(\neg\chi)$ and assume that:

$$(f_1, \ldots, f_s)(\bar{a}_I, \bar{b}_I) := \bar{c}.$$ 

Then, $(\bar{a}, 0, 0, 0)$ and $(\bar{b}, 0, 0, 1) \in X_\phi$. Since $F$ is an aggregator for $X_\phi$, it must hold that:

$$F((\bar{a}, 0, 0, 0), (\bar{b}, 0, 0, 1)) = (\bar{c}, \bar{a}_J, 0, 0, 1) \in X_\phi,$$

which, by (2), implies that $(\bar{c}, \bar{a}_J) \in \text{Mod}(\neg\chi)$. Furthermore, again since $F$ is an aggregator for $X_\phi$, it must be the case that:

$$F((\bar{c}, \bar{a}_J, 0, 0, 1), (\bar{a}, 0, 0, 0)) = (\bar{c}, \bar{a}_J, 0, 0, 0) \in X_\phi,$$

which, by (2), implies that $(\bar{c}, \bar{a}_J) \in \text{Mod}(\chi)$. Thus, $(\bar{c}, \bar{a}_J) \in \text{Mod}(\chi) \cap \text{Mod}(\neg\chi)$. Contradiction.

By Claims 4.1.6 and Corollary 2.4, $X_\phi$ is a possibility domain if and only if it admits a binary non-dictatorial aggregator such that there exists a $d \in \{1, 2\}$ and a non-empty $J \subseteq \{1, \ldots, k\}$, where, for all $j \in J \cup \{k+1, k+2, k+3\}$, $f_j = \text{pr}_d^2$. It is not difficult to see that such an aggregator exists for $d = 1$ if and only if it does for $d = 2$. Thus, we can safely assume that $d = 1$.

Before proving that our reduction works, we need some notation. For a domain $Y \subseteq \{0, 1\}^m$ and a non-empty set of indices $I \subseteq \{1, \ldots, m\}$, let $Y_I$ be the projection of $Y$ to the indices of $I$, that is, the set of partial vectors with coordinates in $I$ that can be extended to vectors of $Y$. Also, for two domains $Y, Z \subseteq \{0, 1\}^m$ of size $n$, viewed as $n \times m$ matrices, we write $Y \approx Z$ if, by permuting the columns of $Z$, we can obtain $Y$. 

First, assume that there exist $1 < l < k$ variables $x_1, \ldots, x_l \in \{x_1, \ldots, x_k\}$ such that $\chi$ is independent from all of them. Let also $J = \{1, \ldots, k\} \setminus \{i_1, \ldots, i_l\}$. Then, (2) can be written as:

$$X_\phi \approx \{0,1\}^I \times \left( \left( \text{Mod}(\chi)_J \times \{(0,0,0),(1,1,1)\} \right) \cup \left( \text{Mod}(\neg \chi)_J \times \text{Imp} \right) \right).$$

It is straightforward to observe that any $m$-tuple $F = (f_1, \ldots, f_m)$ of binary functions, such that $f_{l+1} = \ldots = f_m = \text{pr}_d^2$, $d = 1, 2$ is an aggregator for $X_\phi$. Thus $X_\phi$ is a possibility domain.

Now, assume that $X_\phi$ is a possibility domain and $F = (f_1, \ldots, f_m)$ a binary non-dictatorial aggregator for $X_\phi$. Let also $(I,J)$ be a partition of $\{1, \ldots, k\}$, such that, for all $j \in J \cup \{k+1, k+2, k+3\}$, $f_j = \text{pr}_d^2$ and for all $i \in I$, $f_i \neq \text{pr}_d^2$. Again, to simplify things, assume that there exists an $s \in \{1, \ldots, k-1\}$ such that $I = \{1, \ldots, s\}$, $J = \{s+1, \ldots, k\}$. We consider the following three cases:

- If $f_i := \text{pr}_d^2$, for all $i \in I$, we show that $\chi$ is independent from $x_1, \ldots, x_s$. Suppose there exist vectors $\vec{a}, \vec{b} \in \{0,1\}^s$ and $\vec{c} \in \{0,1\}^{k-s}$, such that $(\vec{a}, \vec{c}) \in \text{Mod}(\chi)$ and $(\vec{b}, \vec{c}) \in \text{Mod}(\neg \chi)$. Then, $(\vec{a}, \vec{c}, 0, 0, 0) \in X_\phi$ and $(\vec{a}, \vec{c}, 0, 0, 1) \in X_\phi$. Since $F$ is an aggregator for $X_\phi$, it must hold that:

$$F((\vec{a}, \vec{c}, 0, 0, 0), (\vec{b}, \vec{c}, 0, 0, 1)) = (\vec{b}, \vec{c}, 0, 0, 0) \in X_\phi,$$

which, by (2), implies that $(\vec{b}, \vec{c}) \in \text{Mod}(\chi) \cap \text{Mod}(\neg \chi)$. Contradiction. Since $\vec{a}, \vec{b}$ and $\vec{c}$ where chosen arbitrarily, it follows that $\chi$ is independent from $x_1, \ldots, x_s$.

- If $f_i$ is symmetric, for all $i \in I$, we show that $\chi$ is independent from $x_1, \ldots, x_s$. Suppose there exist vectors $\vec{a}, \vec{b} \in \{0,1\}^s$ and $\vec{c} \in \{0,1\}^{k-s}$, such that $(\vec{a}, \vec{c}) \in \text{Mod}(\chi)$ and $(\vec{b}, \vec{c}) \in \text{Mod}(\neg \chi)$. Also, assume that $(f_1, \ldots, f_s)(\vec{a}, \vec{b}) := \vec{z}$. Then, $(\vec{a}, \vec{c}, 0, 0, 0) \in X_\phi$ and $(\vec{b}, \vec{c}, 0, 0, 1) \in X_\phi$. Since $F$ is an aggregator for $X_\phi$, it must hold that:

$$F((\vec{a}, \vec{c}, 0, 0, 0), (\vec{b}, \vec{c}, 0, 0, 1)) = (\vec{z}, \vec{c}, 0, 0, 0) \in X_\phi,$$

$$F((\vec{b}, \vec{c}, 0, 0, 1), (\vec{a}, \vec{c}, 0, 0, 0)) = (\vec{z}, \vec{c}, 0, 0, 1) \in X_\phi,$$

which, by (2), implies that $(\vec{z}, \vec{c}) \in \text{Mod}(\chi) \cap \text{Mod}(\neg \chi)$. Contradiction. Since $\vec{a}, \vec{b}$ and $\vec{c}$ where chosen arbitrarily, it follows that $\chi$ is independent from $x_1, \ldots, x_s$.

- If there is a partition $(I_1, I_2)$ of $I$, such that $f_i = \text{pr}_d^2$ for all $i \in I_1$ and $f_i$ is symmetric for all $i \in I_2$, we show that $\chi$ is independent from all $x_i$ such that $i \in I_1$. Assume again w.l.o.g. that there is a $t \in \{1, \ldots, s-1\}$ such that $I_1 = \{1, \ldots, t\}$ and $I_2 = \{t+1, \ldots, s\}$. Suppose there exist vectors $\vec{a}, \vec{b} \in \{0,1\}^t$ and $\vec{c} \in \{0,1\}^{k-t}$, such that $(\vec{a}, \vec{c}) \in \text{Mod}(\chi)$ and $(\vec{b}, \vec{c}) \in \text{Mod}(\neg \chi)$. Then, $(\vec{a}, \vec{c}, 0, 0, 0) \in X_\phi$ and $(\vec{a}, \vec{c}, 0, 0, 1) \in X_\phi$. Since $F$ is an aggregator for $X_\phi$, it must hold that:

$$F((\vec{a}, \vec{c}, 0, 0, 0), (\vec{b}, \vec{c}, 0, 0, 1)) = (\vec{b}, \vec{c}, 0, 0, 0) \in X_\phi,$$

which, by (2), implies that $(\vec{b}, \vec{c}) \in \text{Mod}(\chi) \cap \text{Mod}(\neg \chi)$. Contradiction. Since $\vec{a}, \vec{b}$ and $\vec{c}$ where chosen arbitrarily, it follows that $\phi$ is independent from $x_1, \ldots, x_t$.

This concludes the proof of both the reduction and Theorem 4.1.
We now show the analogous result for local possibility domains. Fortunately, the proofs of the bounds here are relatively shorter.

**Theorem 4.2.** Deciding, on input $\phi$, whether or not $X_\phi$ admits a locally non-dictatorial aggregator is (i) in $\Sigma_2^P \cap \Pi_2^P$ and (ii) coNP-hard.

**Proof** (i) We follow the proof of Theorem 4.1. By Corollary 3.4 we have only three functions, namely $\land^{(3)}$, $\lor^{(3)}$, $\oplus$, which, when combined to an $m$-ary tuple $F = (f_1, \ldots, f_m)$, form a local non-dictatorial aggregator for $X$. Thus, the proof is exactly the same, with the difference that we now have $3^m$ tuples that can be encoded as $(6 \times 3)m$-binary sequences and we conclude that the problem is in $\Sigma_2^P$.

For the containment in $\Pi_2^P$, we argue as follows. Given access to $H_{X_\phi}$ we can, by Corollary 3.5 obtain in polynomial time a ternary WNU aggregator $G = (g_1, \ldots, g_m)$ such that $X_\phi$ is a local possibility domain if and only if it admits $G$. Whether $X_\phi$ admits $G$ or not is in coNP (in the same way we check if $X_\phi$ is affine) and thus in $\Pi_2^P$ too. Since the size of $H_{X_\phi}$ is polynomial in that of $\phi$, it suffices to show that testing whether there is no edge $uu' \rightarrow vv'$ in $H_{X_\phi}$ is in $\Pi_2^P$. This problem can be expressed as:

For all assignments $\bar{a} = (a_1, \ldots, a_m)$, $\bar{b} = (b_1, \ldots, b_m)$, there exists an assignment $\bar{c} = (c_1, \ldots, c_m)$ such that, if $\bar{a}$, $\bar{b}$ satisfy $\phi$ and $a_i = u$, $b_i = u'$, $a_j = v$, $b_j = v'$, then $\bar{c}$ satisfies $\phi$, $c_i = u$, $c_j = v'$ and $c_k \in \{a_k, b_k\}$ for all $k \in \{1, \ldots, m\} \setminus \{i, j\}$.

Thus, the proof is complete.

(ii) We show that the problem of whether a logical formula $\chi$, defined on $k$ variables $x_1, \ldots, x_k$, is unsatisfiable, reduces to that of deciding if the truth set of a formula is a local possibility domain.

Let $\psi(y_1, y_2, y_3)$ be the propositional formula with $\text{Mod}(\psi) = \text{Imp}$, where $\{y_1, y_2, y_3\} \cap \{x_1, \ldots, x_k\} = \emptyset$. Consider the formula:

$$\phi = (\chi(x_1, \ldots, x_k) \land \psi(y_1, y_2, y_3)) \lor (z \rightarrow w),$$

where $z$ and $w$ are variables not among those of $\chi$ or $\psi$. First note that the length of $\phi$ is again linear to that of $\chi$, since $|\phi| = |\chi| + 8$ and thus the construction is polynomial.

Let $m := k + 5$. We prove the following claim.

**Claim 4.2.1.** $\chi$ is unsatisfiable if and only if

$$X_\phi = \left(\text{Mod}(\chi) \times \text{Imp} \times \{0, 1\}^2\right) \cup \left(\{0, 1\}^{k+3} \times \{(0, 0), (0, 1), (1, 1)\}\right),$$

is a local possibility domain.

**Proof of Claim:** First, assume $\chi$ is unsatisfiable. Then, $X_\phi$:

$$X_\phi = \{0, 1\}^{k+3} \times \{(0, 0), (0, 1), (1, 1)\},$$

which is a local possibility domain, since it admits for example the binary aggregator $F = (f_1, \ldots, f_m)$, where $f_j = \land$, $j = 1, \ldots, m$.

On the other hand, let $\text{Mod}(\phi)$ be a local possibility domain, and assume $\chi$ is satisfiable by some assignment $\bar{a} = (a_1, \ldots, a_k)$. Since $\text{Mod}(\phi)$ is a local possibility domain, by Theorem 4.1 it admits a ternary locally non-dictatorial aggregator $F = (f_1, \ldots, f_m)$.
By Lemma 4.2, \( \text{Imp} \) is an impossibility domain. Thus, there exist \( \bar{b}^i = (b_1^i, b_2^i, b_3^i) \in \text{Imp}, i = 1, 2, 3, \) such that:

\[
\bar{c} := (f_{k+1}, f_{k+2}, f_{k+3})(\bar{b}^1, \bar{b}^2, \bar{b}^3) \notin \text{Imp}.
\]

Since \( \bar{b}^1, \bar{b}^2, \bar{b}^3 \in \text{Imp} \), it holds that \( (\bar{a}, \bar{b}^i, 1, 0) \in X_\phi \), for \( i = 1, 2, 3 \). On the other hand:

\[
F((\bar{a}, \bar{b}^1, 1, 0), (\bar{a}, \bar{b}^2, 1, 0), (\bar{a}, \bar{b}^3, 1, 0)) = (\bar{a}, \bar{c}, 1, 0) \notin X_\phi.
\]

Thus \( F \) is not an aggregator for \( X_\phi \). Contradiction. \( \square \)

This concludes the proof of Theorem 4.2.

4.3. Agendas. Suppose now that we have an agenda \( \bar{\phi} = (\phi_1, \ldots, \phi_m) \). We prove the following upper and lower bounds to the complexity of deciding whether \( X_{\bar{\phi}} \) is a (local) possibility domain. For upper bounds, we use a version of Lemma 4.1 tailored for agendas.

Lemma 4.3. Let \( F = (f_1, \ldots, f_m) \) be an \( m \)-tuple of \( n \)-ary conservative and polynomial-time computable functions. Deciding, given the agenda \( \bar{\phi} = (\phi_1, \ldots, \phi_m) \), whether \( F \) is an aggregator for \( X_{\bar{\phi}} \) is in \( \Pi^P_2 \).

Proof The result is immediate since the problem can be cast as follows:

For all \( m \)-tuples \( \bar{x}^1, \ldots, \bar{x}^n \in \{0, 1\}^n \), if \( \bigwedge_{j=1}^m \phi_j^{x_j^1}, \ldots, \bigwedge_{j=1}^m \phi_j^{x_j^n} \) are all satisfiable, then so is \( \bigwedge_{j=1}^m \phi_j^{w_j} = F(x_j^1, \ldots, x_j^n) \), and since checking if a formula is satisfied by a specific assignment can be done in polynomial time. \( \square \)

In terms of lower bounds, a straightforward idea would be to construct, given an integrity constraint, an agenda with the same domain, since that would immediately imply that the lower bounds for the integrity constraints carry on to the agendas. Unfortunately, as discussed above, this is an \( \text{FNP} \)-complete problem. However, by Endriss et al. [15, Proposition 3], we can obtain the following result.

Corollary 4.1. Given an integrity constraint \( \phi \) and a satisfying assignment \( \bar{a} \) of \( \phi \), we can construct an agenda \( \bar{\phi} \), of polynomial size in the length of \( \phi \), such that \( X_{\bar{\phi}} = X_\phi \). Furthermore, this construction is polynomial in the size of \( \phi \).

Corollary 4.1 follows directly from the proof of [15, Proposition 3]. The reason this result does not imply the existence of a polynomial reduction, is that to construct \( \bar{\phi} \), one needs a satisfying assignment of \( \phi \). And of course, finding such an assignment is intractable. Fortunately, we can get past that in the problems we consider.

Theorem 4.3. Given the agenda \( \bar{\phi} = (\phi_1, \ldots, \phi_m) \), the question whether \( X_{\bar{\phi}} \) admits a non-dictatorial aggregator is (i) in \( \Delta^P_3 \) and (ii) \( \text{coNP} \)-hard.

Proof (i) We will show that the problem can be decided in \( P \) with an oracle in \( \Sigma^P_2 \). By Corollary 2.1, \( X_{\bar{\phi}} \) is a possibility domain if and only if it is affine or it admits a binary non-dictatorial aggregator. The problem of whether \( X_{\bar{\phi}} \) is affine is in \( \Pi^P_2 \subset \Delta^P_3 \) by Lemma 4.3 using \( \oplus \) as the aggregator.

It remains to show that the latter problem, or equivalently the problem of checking if \( H_{X_{\bar{\phi}}} \) is strongly connected, is in \( \Delta^P_3 \). Since \( H_{X_{\bar{\phi}}} \) has \( 2m \) vertices, its size is polynomial in that of the agenda. Also, checking if a graph is strongly connected
is in \( P \). Thus it suffices to show that \( H_{X_\phi} \) can be constructed within polynomial time with an oracle in \( \Sigma_2^P \).

Claim 4.3.1. Given the agenda \( \bar{\phi} = (\phi_1, \ldots, \phi_m) \), the graph \( H_{X_\phi} \) can be constructed within polynomial time in the size of \( \bar{\phi} \) with an oracle in \( \Sigma_2^P \).

Proof of Claim: Consider two vertices \( uu_1' \) and \( vv_1' \) of \( H_{X_\bar{\phi}} \), with \( s \neq t \). To decide if there is an edge from \( uu_1' \) to \( vv_1' \), it is sufficient to check the following:

- both \( \bigwedge_{i=1}^m \phi_{i,j} \) and \( \bigwedge_{j=1}^m \phi_{j,i} \) are satisfiable,
- \( x_s = u, x_t = v, y_s = u' \) and \( y_t = v' \) and
- for all \( m \)-sequences \( \bar{x} \), either \( \bigwedge_{j=1}^m \phi_{j,j} \) is not satisfiable or at least one of the following is not true: (i) \( z_k = u \), (ii) \( z_l = v' \), (iii) \( z_j \in \{x_j, y_j\} \) for \( j = 1, \ldots, m \).

Notice that this can be done with an oracle in \( \Sigma_2^P \). \( \square \)

(ii) Let \( \chi(x_1, \ldots, x_k) \) be a propositional formula on \( k \) variables. We construct, in polynomial time, an agenda \( \phi \) such that \( \chi \) is independent from at least one of its variables if and only if \( X_{\bar{\phi}} \) is a possibility domain. In all that follows, \( m = k + 3 \).

Let:

\[
\phi(x_1, \ldots, x_k,y_1,y_2,y_3) = \chi(x_1, \ldots, x_k) \oplus \psi(y_1, y_2, y_3),
\]

where: \( \{x_1, \ldots, x_k\} \) and \( \{y_1, y_2, y_3\} \) are disjoint sets of variables and \( \text{Mod}(\psi) = \text{Imp} \).

As in Theorem 4.1, we have that \( \phi \)'s length is linear to that of \( \chi \) and that:

\[
X_{\phi} = \left( \text{Mod}(\chi) \times \{(0,0,0), (1,1,1)\} \right) \cup \left( \text{Mod}(-\chi) \times \text{Imp} \right).
\]

Pick an arbitrary vector \( \bar{a} = (a_1, \ldots, a_k) \in \{0,1\}^k \) and set:

\[
\bar{b} = (b_1, \ldots, b_m) := \begin{cases} (a_1, \ldots, a_k, 0, 0, 0) & \text{if } \chi(a_1, \ldots, a_k) = 1, \\ (a_1, \ldots, a_k, 0, 0, 1) & \text{else.} \end{cases}
\]

In both cases, \( \bar{b} \) satisfies \( \phi \). Thus, we can use Corollary 4.1 to construct an agenda \( \phi \) such that \( X_{\bar{\phi}} = X_{\phi} \), whose size is polynomial in the length of \( \phi \) and thus in that of \( \chi \) too. Since deciding whether \( \bar{a} \) satisfies \( \chi \) or not can be done in polynomial time, our construction is polynomial. Also, in Claim 4.1.1 of Theorem 4.1, we prove that \( \chi \) is independent from at least one of its variables if and only if \( X_{\phi} \), and thus \( X_{\bar{\phi}} \) too, is a possibility domain. \( \square \)

In what concerns local possibility domains, we have the analogous bounds.

Theorem 4.4. Given the agenda \( \bar{\phi} = (\phi_1, \ldots, \phi_m) \), the question of whether \( X_{\bar{\phi}} \) admits a locally non-dictatorial aggregator is (i) in \( \Delta_3^P \) and (ii) \( \text{coNP} \)-hard.

Proof (i) We have already argued in Claim 4.3.1 that \( H_{X_{\phi}} \) can be constructed in polynomial time with an oracle in \( \Sigma_2^P \). Then, by Corollary 3.3 we can obtain, in polynomial time, a maximum symmetric aggregator \( F = (f_1, \ldots, f_m) \) for \( X \). We can easily now obtain the aggregator \( G = (g_1, \ldots, g_m) \) for \( X \) of the first paragraph Corollary 3.3, where \( g_j \in \{\chi^{(3)}, \chi^{(3)} \oplus \} \), \( j = 1, \ldots, m \). Furthermore, testing whether \( X_{\bar{\phi}} \) admits this aggregator is in \( \Pi_2^P \) by Lemma 4.3.

(ii) Let \( \chi(x_1, \ldots, x_k) \) be a propositional formula. We construct an agenda \( \bar{\phi} \) such that \( X_{\bar{\phi}} \) is a local possibility domain if and only if \( \chi \) is unsatisfiable.
Let $\psi(y_1, y_2, y_3)$ be again the propositional formula with $\text{Mod}(\psi) = \text{Imp}$, where $\{y_1, y_2, y_3\} \cap \{x_1, \ldots, x_k\} = \emptyset$. Consider the formula:

$$\phi = (\chi(x_1, \ldots, x_k) \land \psi(y_1, y_2, y_3)) \lor (z \rightarrow w),$$

where $z$ and $w$ are variables not among those of $\chi$ or $\psi$.

Let $m := k + 5$. By (3) we have that:

$$X_\phi = \left(\text{Mod}(\chi) \times \text{Imp} \times \{0, 1\}^2\right) \cup \left(\{0, 1\}^{k+3} \times \{(0, 0), (0, 1), (1, 1)\}\right).$$

Again, pick an arbitrary vector $\bar{a} = (a_1, \ldots, a_k) \in \{0, 1\}^k$ and set:

$$\bar{b} = (b_1, \ldots, b_m) := (a_1, \ldots, a_k, 0, 0, 0, 0).$$

$\bar{b}$ satisfies $\phi$. Thus, we can use Proposition 3 of [15], to construct an agenda $\bar{\phi}$ such that $X_{\bar{\phi}} = X_\phi$, whose size is polynomial in the length of $\phi$ and thus in that of $\chi$ too. Also, in Claim 4.2.1, we prove that $\chi$ is unsatisfiable if and only if $X_\phi$, and thus $X_{\bar{\phi}}$ too, is a local possibility domain.

A related result, that has been answered in [16], is whether the domain of an agenda admits the majority aggregator. In [34] and [16], such agendas are characterized as those satisfying the median property, that is, agendas whose every inconsistent subset, contains an inconsistent subset of size 2. Endriss et al. [16] show that checking if an agenda satisfies the median property is $\Pi^P_2$-complete. Unfortunately, this does not extend to the problem of determining if the domain of an agenda is a possibility domain, since, even though checking for the minority aggregator is in $\Pi^P_2$, the existence of binary non-dictatorial aggregators seems to be a harder problem.

**Remark 2.** It is clear that the upper and lower complexity bounds obtained here do not match. By Theorem 4.3 and Theorem 4.4, it is also clear that the gap between the upper and lower bounds in the case of the agendas comes from the fact that the lower bounds are obtained via the integrity constraints.

What is not so clear, however, is why in the case of integrity constraints the upper bound is $\Sigma^P_2 \cap \Pi^P_2$ and in the case of the agendas the upper bound is $\Delta^P_3$, whereas one might expect a full computational jump in the $\text{PH}$, or for the bounds to be the same. First, note that, in the case of the integrity constraints, it does not seem plausible to construct $H_{X_\phi}$ in polynomial time, with access only to an NP oracle. This is so because, to decide if there is an edge $uv_{\phi} \rightarrow vv_1$ in $H_X$, one needs to “guess” two satisfying assignments for $\phi$, such that there is no other satisfying assignment with certain properties. This naturally points to an existential and a universal certificate, something that an NP oracle alone cannot provide. On the other hand, for the same reason, it seems improbable that finding an aggregator $F$ for $X_\phi$ can be in $\Sigma^P_2$, since we need to guess a candidate $F$, such that for all vectors of 0/1 judgments for the formulas of the agenda, we can decide the satisfiability of a specific formula. This again needs more certificates than $\Sigma^P_2$ (or $\Pi^P_2$) can provide.

The above arguments justify only why our proofs do not yield any better complexity bounds. Naturally, it is conceivable that other approaches may yield tighter bounds.

4.4. Other Types of Non-dictatorial Aggregation. In this subsection, we quickly extend the results of the previous subsections in four cases of non-dictatorial aggregation that have been used in the literature. Namely, we discuss generalized
dictatorships, anonymous, monotone and systematic aggregators. We only consider the case where we search if an implicitly given Boolean domain admits such aggregators. The case where the domain is given explicitly has been shown to be tractable by Diaz et al. [9], since the results there directly provide the required aggregators.

4.4.1. Generalized Dictatorships. We begin by defining generalized dictatorships, that is, aggregators whose output is always a vector of the input.

Definition 3. Let \( F = (f_1, \ldots, f_m) \) be an \( m \)-tuple of \( n \)-ary conservative functions. \( F \) is a generalized dictatorship for a domain \( X \subseteq \{0,1\}^m \), if, for any \( x^1, \ldots, x^n \in X \), it holds that:

\[
F(x^1, \ldots, x^n) := (f_1(x_1), \ldots, f_m(x_m)) \in \{x^1, \ldots, x^n\}.
\]

Obviously, generalized dictatorships of a domain \( X \) are always aggregators for \( X \). Generalized dictatorships were first defined by Grandi and Endriss [18], where they were defined independently of a specific domain. That is, Eq. (6) holds for all \( x^1, \ldots, x^n \in \{0,1\}^m \) in their context. With this stronger definition, Grandi and Endriss [18, Theorem 16] show that the class of generalized dictators coincides with that of functions that are aggregators for every domain \( X \subseteq \{0,1\}^m \).

Generalized dictatorships select a possibly different dictator for each input. All dictatorial aggregators are obviously generalized dictatorships. Depending on the domain, different kinds of non-dictatorial aggregators can be generalized dictatorships. For example, \( \text{maj} \) and \( \oplus \) are both generalized dictatorships for any domain with only two elements. In fact, any domain with only two elements admits only generalized dictatorships as aggregators. The following characterization has been proven in [9].

Theorem F. [9, Theorem 11] A domain \( X \subseteq \{0,1\}^m \) admits an aggregator that is not a generalized dictatorship if and only if it is a possibility domain with at least three elements.

Using that, we can easily prove the same complexity bounds we had for deciding if the domain of an integrity constraint admits a non-dictatorial aggregator.

Corollary 4.2. Deciding, on input \( \phi \), whether \( X_\phi \) admits an aggregator that is not a generalized dictatorship is (i) in \( \Sigma^p_2 \cap \Pi^p_2 \) and (ii) coNP-hard.

Proof By Theorem [F] it suffices to show that deciding if \( X_\phi \) has at least three elements is in \( \Sigma^p_2 \cap \Pi^p_2 \). Indeed, this can be written as:

There exist tuples \( \bar{x}, \bar{y}, \bar{z} \in \{0,1\}^m \) that are pairwise distinct, such that all three satisfy \( \phi \).

Thus, deciding if \( |X_\phi| \geq 3 \) is in \( \Sigma^p_2 \subseteq \Sigma^p_2 \cap \Pi^p_2 \). The rest of the proof is identical with that of Theorem [4.1].

(ii) Immediate by Theorems [F] and [4.1] since the domain of \( \bar{\phi} \) has more than two elements.

In case the domain is provided via an agenda, we can again easily obtain the same bounds.

Corollary 4.3. Given the agenda \( \bar{\phi} = (\phi_1, \ldots, \phi_m) \), the question whether \( X_{\bar{\phi}} \) admits an aggregator that is not a generalized dictatorship is (i) in \( \Delta^p_3 \) and (ii) coNP-hard.
Proof (i) Again by Theorem F, it suffices to show that deciding whether \( X_{\phi} \) has at least three elements is in \( \Delta^P_3 \). Indeed, the problem can be written as:

There exist \( m \)-tuples \( \bar{x}, \bar{y}, \bar{z} \in \{0,1\}^m \) which are pairwise distinct and such that \( \bigwedge_{j=1}^m \phi_{\bar{x}^j}^i \cdot \bigwedge_{j=1}^m \phi_{\bar{y}^j}^j \) and \( \bigwedge_{j=1}^m \phi_{\bar{z}^j}^j \) are all satisfiable.

Thus, it is in \( \Sigma^P_2 \subseteq \Delta^P_3 \). The rest of the proof is identical that of Theorem 4.3.

(ii) Immediate by Theorems F and 4.3, since the domain in (4) has more than two elements.

\[ \square \]

4.4.2. Anonymous aggregators. An aggregator is anonymous if it is not affected by permutations of its input. Such an aggregator treats each member of the population “fairly”, in the sense that the outcome of the aggregation depends only on the votes that have been cast and not on which person selected which options.

Definition 4. Let \( X \subseteq \{0,1\}^m \). An \( n \)-ary aggregator \( F = (f_1, \ldots, f_m) \) for \( X \) is anonymous, if it holds that for all \( j \in \{1, \ldots, m\} \) and for any permutation \( p : \{1, \ldots, n\} \mapsto \{1, \ldots, n\} \):

\[
f_j(a_1, \ldots, a_n) = f_j(a_{p(1)}, \ldots, a_{p(n)}),
\]

for all \( a_1, \ldots, a_n \in \{0,1\} \).

It is immediate to observe that a ternary such aggregator is always WNU. Thus, using Theorem D Kirousis et al. proved the following result.

Corollary 4.4. [24, Corollary 5.11] \( X \subseteq \{0,1\}^m \) is a local possibility domain if and only if it admits an anonymous aggregator.

In fact, a local possibility domain always admits a ternary such aggregator. We can now obtain all the complexity bounds we have for local non-dictatorial aggregators, in the case where we search for anonymous ones.

Corollary 4.5. A. Deciding, on input \( \phi \), whether \( X_{\phi} \) admits an anonymous aggregator is i. in \( \Sigma^P_3 \cap \Pi^P_2 \) and ii. \( \text{coNP} \)-hard.

B. Given the agenda \( \bar{\phi} = (\phi_1, \ldots, \phi_m) \), the question whether \( X_{\bar{\phi}} \) admits an anonymous aggregator is i. in \( \Delta^P_3 \) and ii. \( \text{coNP} \)-hard.

Proof

Ai. Immediate by Corollary 4.4 and Theorem 4.2

Aii. Immediate by Corollary 4.4 and Theorem 4.2

Bi. Immediate by Corollary 4.4 and Theorem 4.4

Bii. Immediate by Corollary 4.4 and Theorem 4.4

\[ \square \]

4.4.3. Monotone aggregators. Monotone aggregators are aggregators whose output does not change if more individuals agree with it. This is one of the features that makes majority voting appealing.

Definition 5. Let \( X \subseteq \{0,1\}^m \). An \( n \)-ary aggregator \( F = (f_1, \ldots, f_m) \) for \( X \) is monotone, if it holds that for all \( j \in \{1, \ldots, m\} \) and for all \( i \in \{1, \ldots, n\} \):

\[
f_j(a_1, \ldots, a_{i-1}, 0, a_{i+1}, \ldots, a_n) = 1 \Rightarrow f_j(a_1, \ldots, a_{i-1}, 1, a_{i+1}, \ldots, a_n) = 1.
\]

It is not difficult to see that all binary aggregators (both dictatorial and non-dictatorial) have that property. Also, in [10] and [24], it has been proven that if a domain admits a majority aggregator, it also admits a binary non-dictatorial one. Combining this with Corollary 2.1 we obtain the following result.
Theorem G. [9, Theorem 12] A domain $X \subseteq \{0,1\}^m$ admits a monotone non-dictatorial aggregator of some arity if and only if it admits a binary non-dictatorial one.

Thus we can again easily obtain the required complexity bounds.

Corollary 4.6. A. Deciding, on input $\phi$, whether $X_\phi$ admits a monotone non-dictatorial aggregator is i. in $\Sigma^P_2 \cap \Pi^P_2$ and ii. coNP-hard.

B. Given the agenda $\bar{\phi} = (\phi_1, \ldots, \phi_m)$, the question whether $X_{\bar{\phi}}$ admits a monotone non-dictatorial aggregator is i. in $\Delta^P_3$ and ii. coNP-hard.

Proof

Ai. Immediate by Theorem G and Theorem 4.1

Aii. Immediate by Theorem G and by noticing that the only available aggregators for the construction of (2) in Theorem 4.2 are binary non-dictatorial ones.

Bi. Immediate by Theorem G and Theorem 4.3

Bii. Immediate by Theorem G and by noticing that the only available aggregators for the construction of (4) in Theorem 4.3 are binary non-dictatorial ones. $\square$

4.4.4. Systematic aggregators. Systematicity is the requirement that an aggregator treats all issues in the same way. This can be a very natural requirement for a set of issues of the same nature. We have already seen that systematic aggregators of a domain correspond to polymorphisms. Recall that we denote a systematic aggregator $F = (f_1, \ldots, f_m)$, where $f_1 = \cdots = f_m = f$, by $\bar{f}$.

Polymorphisms have been extensively studied in the literature and they play a central role in Post's seminal work, where he provides a full classification of Boolean clones, that is sets of Boolean functions closed under composition. Post's work can provide results in Complexity Theory too; see for example [3, 4, 20, 21]. Here, we use a result concerning the unanimous polymorphisms (equivalently, the systematic aggregators), that a Boolean domain admits. We say that an $n$-ary function $f$ is essentially unary, if there exists a unary Boolean function $g$ and an $i \in \{1, \ldots, n\}$, such that:

$$f(x_1, \ldots, x_n) = g(x_i),$$

for all $x_1, \ldots, x_n \in \{0,1\}$. Obviously, the only unanimous such functions are the projections.

Corollary 4.7. Let $X \subseteq \{0,1\}^n$ be a Boolean domain. Then, either $X$ admits only essentially unary functions, or it is closed under $\land, \lor, \text{maj}$ or $\oplus$.

This result can be obtained directly by Post’s Lattice, without considering complexity theoretic notions. For a direct algebraic approach, see also [42, Proposition 1.12] (by noting that the only Boolean semi-projections of arity at least 3 are projections).

Corollary 4.7 translates in our framework as follows.

Corollary 4.8. Let $X \subseteq \{0,1\}^n$ be a Boolean domain. Then $X$ admits a systematic non-dictatorial aggregator if and only if it admits the aggregators $\land, \lor, \text{maj}$ or $\oplus$.

In case of integrity constraints, the problem of detecting if their domains admit systematic non-dictatorial aggregators is coNP-complete.
Proposition 4.1. Deciding, on input $\phi$, whether $X_\phi$ admits a systematic non-dictatorial aggregator is coNP-complete.

Proof Checking closure under $\land$, $\lor$, $\text{maj}$ and $\oplus$ is in coNP by Lemma 4.1. Thus we only need to show coNP-hardness. We reduce from the known coNP-complete problem of tautology, where we check if a propositional formula is satisfied by all assignments of values.

Let $\chi(x_1,\ldots,x_k)$ be the input propositional formula on $k$ variables, and $\psi(y_1,y_2,y_3)$ be the formula such that $\text{Mod}(\psi) = \text{Imp}$, where $\{x_1,\ldots,x_m\} \cap \{y_1,y_2,y_3\} = \emptyset$. Let also $m = k + 3$.

Consider the formula:

$$\phi(x_1,\ldots,x_m,y_1,y_2,y_3) = \chi \lor \psi.$$  

If $\chi$ is a tautology, $X_\phi = \{0,1\}^m$, which is closed under $\land$, $\lor$, $\text{maj}$ and $\oplus$. Otherwise:

$$X_\phi = \left(\text{Mod}(\chi) \times \{0,1\}^3\right) \cup \left(\text{Mod}(\neg \chi) \times \text{Imp}\right).$$

Easily now, if $\bar{a} = (a_1,\ldots,a_k)$ does not satisfy $\phi$, and $f \in \{\land,\lor,\text{maj},\oplus\}$, it holds that $(\bar{a},0,0,1), (\bar{a},0,1,0), (\bar{a},1,0,0) \in X_\phi$, but:

$$\bar{b} := \bar{f}(\bar{a},1,0,0), (\bar{a},0,1,0), (\bar{a},1,0,0) = \{(\bar{a},0,0,0),(\bar{a},1,1,1)\}.$$  

Thus, since $\bar{b} \notin X_\phi$, $X_\phi$ does not admit any systematic non-dictatorial aggregator. \(\square\)

Finally, we can obtain the corresponding results in the case the domain is provided via an agenda.

Proposition 4.2. Deciding, on input $\bar{\phi} = (\phi_1,\ldots,\phi_m)$, whether $X_{\bar{\phi}}$ admits a systematic non-dictatorial aggregator is in $\Pi^P_2$ and coNP-hard.

Proof By Lemma 4.1 we have membership in $\Pi^P_2$ for detecting closure under $\land$, $\lor$, $\text{maj}$ and $\oplus$. For coNP-hardness, observe that given a formula $\chi$, we can again set $\phi = \chi \lor \psi$ and construct an agenda whose domain is the same with $X_{\bar{\phi}}$ of Proposition 4.1 in polynomial time, by Endriss et al. [15] Proposition 3]. Thus, the same reduction as in Proposition 4.1 works. \(\square\)

5. Concluding Remarks

In this paper, we established the first results concerning the tractability of non-dictatorial aggregation. Specifically, we gave polynomial-time algorithms that take as input a set $X$ of feasible evaluations and determine whether or not $X$ is a possibility domain and a uniform possibility domain, respectively. In these algorithms, the set $X$ of feasible evaluations is given to us explicitly, i.e., $X$ is given by listing all its elements. We also provided upper and lower bounds for the complexity of deciding if a domain $X$ is a possibility or a local possibility domain, in case it is given implicitly, either via an integrity constraint or by an agenda. Finally, we extended these results to other types of commonly used non-dictatorial aggregators. These bounds are preliminary, in the sense that they are not tight, especially in case the domains are provided via agendas. This merits further investigation, because implicitly given domains occur frequently in the field of judgment aggregation.

The work reported here assumes that the aggregators are conservative, an assumption that has been used heavily throughout the paper. There is a related, but weaker, notion of an idempotent (or Paretian) aggregator $F = (f_1,\ldots,f_m)$
where each $f_j$ is assumed to be an idempotent function, i.e., for all $x \in X_j$, we have that $f(x, \ldots, x) = x$. Clearly, every conservative aggregator is idempotent. In the Boolean framework, idempotent aggregators are conservative, but, in the non-Boolean framework, this need not hold. It remains an open problem to investigate the computational complexity of the existence of non-dictatorial idempotent aggregators in the non-Boolean framework.

Another line of research could be to consider the aggregators in Subsection 4.4 in the non-Boolean framework. This changes things in a non-trivial way. For example, Theorem F does not hold in the non-Boolean case, since for example a ternary minority aggregator can be a generalized dictatorship for specific domains. Finally, it would be interesting to follow along the lines of Terzopoulou et al. [44], and consider settings where the individuals are allowed to cast votes on subsets of issues, both in the abstract and in the integrity constraint framework.
