NKX6.3 Regulates Reactive Oxygen Species Production by Suppressing NF-κB and DNMT1 Activities in Gastric Epithelial Cells

Jung Hwan Yoon1, Olga Kim1, Suk Woo Nam1,2, Jung Young Lee1,2 & Won Sang Park1,2

NKX6.3 plays an important role in gastric epithelial differentiation and also acts as a gastric tumor suppressor. The specific aim of this study was to determine whether NKX6.3 contributes to gastric mucosal barrier function by regulating reactive oxygen species (ROS) production. NKX6.3 reduced ROS production and regulated expression of anti-oxidant genes, including Hace1. In addition, NKX6.3 reduced DNMT1 expression and activity by down-regulating NF-κB family gene transcription. Silencing of Hace1 recovered ROS production, whereas knock-down of DNMT1 and NF-κB reduced ROS production and induced Hace1 expression by hypomethylating its promoter region. In addition, NKX6.3 inhibited CagA effects on cell growth, ROS production, and NF-κB and DNMT1 activity. In gastric mucosae and cancers, NKX6.3 and Hace1 expression was significantly reduced. The NKX6.3 expression was positively correlated with Hace1 and Nrf2 genes, but negatively correlated with DNMT1. Hypermethylation of Hace1 gene was observed only in gastric mucosae with H. pylori, atrophy and intestinal metaplasia. Thus, these results suggest that NKX6.3 inhibits ROS production by inducing the expression of Hace1 via down-regulating NF-κB and DNMT1 activity in gastric epithelial cells.

Gastric cancer has a high incidence in Asia and is a leading cause of cancer death in the region1. Cellular damage from various agents and chronic infection with H. pylori most likely influence the risk of gastric carcinogenesis through inflammation-induced reactive oxygen species (ROS) and reactive nitrogen species (RNS) leading to DNA damage in gastric epithelial cells and precancerous cascade including atrophic gastritis, intestinal metaplasia and dysplasia2-4.

The ROS, including superoxide anion radical (•O2−), hydrogen peroxide (H2O2), and hydroxyl radical (•OH), are highly reactive, diffusible, and ubiquitous molecules generated as inevitable by-products of aerobic respiration and metabolism5. In stomach, H. pylori infection induces a strong inflammatory host response, leading to the generation of several ROS and RNS via neutrophils and macrophages6. Imbalance between ROS production and the capacity for detoxification induces an alteration of gene expression7, increased cell death and proliferation, and induction of DNA mutation8. Notably, cancer cells augment intracellular ROS, which contributes to tumorigenesis and cancer progression by promoting genomic instability through increased DNA damage and reduced mismatch repair9. However, as excessive levels of ROS stress can induce cancer cell cycle arrest and apoptosis, cancer cells also increase expression of anti-oxidant proteins to detoxify from ROS and anti-apoptotic proteins10. Thus, manipulating the unique redox regulatory mechanisms of cancer cells might be an effective strategy to eliminate these cells11.

Previously, we and others have reported that the novel transcription factor, NKX6.312, is a key factor for gastric differentiation and prevention of intestinal metaplasia and acts as a tumor suppressor for gastric cancer13-16. ROS is reportedly involved in the development of precancerous gastritis and gastric cancer; hence, we hypothesized that NKX6.3 may protect the gastric mucosal epithelia from harmful ROS.

Herein, we examined the effects of NKX6.3 on ROS production and Hace1, Nrf2, mSOD, catalase, GSH, Nqo1, and Ho-1 expression in mock and NKX6.3 stable AGS and MKN1 cells. In addition, the expression of

Correspondence and requests for materials should be addressed to W.S.P (email: wonsang@catholic.ac.kr)
NKP6.3, Hace1, Nrf2, and DNMT1 was compared between non-neoplastic gastric mucosa and gastric cancers. Overall, we found that NKP6.3 significantly decreased ROS production and regulated the expression of ROS-related genes, including Hace1, by suppressing DNMT1 and NF-kB activity. These results suggest that NKP6.3 plays an important role in gastric epithelial protection and gastric cancer prevention by regulating the ROS levels.

Results

NKP6.3 attenuates ROS production by regulating ROS-responsive genes. To determine whether NKP6.3 contributes to ROS production, we performed in vitro ROS analysis in AGS\textsubscript{Mock}, MKN1\textsubscript{Mock}, AGS\textsubscript{NKP6.3} and MKN1\textsubscript{NKP6.3} cells using DCFDA staining assay. Stable NKP6.3 expression in AGS and MKN1 cells showed reduced cellular ROS levels in a time-dependent manner, as compared to mock stable AGS and MKN1 cells (Fig. 1A–C). To further confirm these initial observations, we measured the expression levels of ROS-related genes, including Hace1, Nox1, Noxa1 and Nrf2, and oxidative stress-responsive genes, including catalase, mNOSOD, GSH, Nqo1 and Ho-1 by real-time RT-PCR and western blotting. Interestingly, NKP6.3 induced the expression of Hace1, Nrf2, catalase, and mNOSOD, while decreasing the expression of Nox1 and Noxa1 proteins. In addition, it also reduced the expression of GSH, Nqo1 and Ho-1 at the mRNA level (Fig. 1D and E). To further support our results, we recapitulated NKP6.3, Hace1 and Nrf2 gene expression patterns from large cohorts of gastric cancer patients available from the National Center for Biotechnology Information (NCBI) Gene Expression Omnibus (GEO) database (accession numbers GSE27342). Interestingly, NKP6.3 expression was positively correlated with Hace1 and Nrf2 expression in gastric cancer cohort (Supplementary Figure S1A). In addition, Hace1 and Nrf2 expression showed a positive correlation (Supplementary Figure S1A). Next, we aimed to determine whether the anti-oxidant activity of NKP6.3 is dependent on Hace1 expression. In AGS and MKN1 cells, treatment with \textit{siHace1} partially recovered ROS production (Fig. 2A) and markedly reduced Nrf2 expression (Fig. 2B). Also, Hace1 silencing in NKP6.3 stable cells decreased GSH, Nqo1 and Ho-1 mRNA expression (Fig. 2C) and showed moderate ablation of NKP6.3-induced cell growth inhibition (Fig. 2D). Thus, it is likely that NKP6.3 attenuates ROS production by Hace1-dependent or –independent regulation of ROS-mediated gene expression.

NKP6.3 induces expression of Hace1-HECT E3 ligase. The Hace1-HECT E3 ligase is a tumor suppressor that directly regulates ROS production, and its reduced expression due to promoter hypermethylation is frequently observed in several cancers\textsuperscript{17}. Since NKP6.3 induced re-expression of Hace1 protein (Fig. 1D), we hypothesized that NKP6.3 functions as a hypomethylating agent. Expectedly, expression of Hace1 mRNA was markedly increased in NKP6.3 stable transfectants (Fig. 2E). Notably, hypermethylation of CpG islands on Hace1 promoter was observed in mock stable AGS and MKN1 cells, whereas de-methylation on Hace1 promoter was detected in NKP6.3 stable transfectants (Fig. 2F). Next, we evaluated the regulatory role of NKP6.3 in DNMT1 expression. As shown in Fig. 3A, NKP6.3 significantly down-regulated expression of DNMT1 mRNA and protein in AGS\textsubscript{NKP6.3} and MKN1\textsubscript{NKP6.3} cells. Knockdown of NF-kB, a transcription factor for DNMT1\textsuperscript{19}, with \textit{siNF-kB} markedly decreased DNMT1 expression at the mRNA and protein levels (Fig. 3B). ChIP assay results indicated that p50 binding to the DNMT1 gene promoter was significantly inhibited by NKP6.3, comparable with the effect of \textit{siNF-kB} (Fig. 3C). In addition, NKP6.3 expression as well as NF-kB silencing significantly decreased DNMT1 activity (Fig. 3D). Knock-down of DNMT1 with \textit{shDNMT1} increased Hace1 mRNA and protein expression (Fig. 3E) and induced de-methylation of Hace1 gene in AGS and MKN1 cells (Fig. 3F). These findings collectively suggest that NKP6.3 induces Hace1 expression by suppressing DNMT1 activity.

NKP6.3 down-regulates NF-kB expression and activity. Next, we investigated whether NKP6.3 regulates NF-kB activity. Interestingly, NKP6.3 markedly down-regulated NF-kB p65 and p50 at the mRNA and protein levels (Fig. 4A–C). We performed ChIP assay, followed by PCR and real-time qPCR, to identify NKP6.3 binding activity within promoter sequences of the NF-kB p65 and p50 genes in AGS\textsubscript{Mock}, MKN1\textsubscript{Mock}, AGS\textsubscript{NKP6.3} and MKN1\textsubscript{NKP6.3} cells. We defined regions upstream of the NF-kB p65 (between −1872 to −1662 bp) and p50 (between −3640 to −3371 bp) genes, overlapping with the transcription start site (TSS) designated 0 bp with 6 and 5 NKP6.3 candidate binding sites (TAAT), respectively. NKP6.3 showed binding activity in these promoter regions of p65 and p50 in AGS and MKN1 cells (Fig. 4D and E). To further confirm that NKP6.3 down-regulates NF-kB expression, we analyzed NF-kB downstream target genes, including interleukin (IL)-6, IL-1\textbeta, and TNF-\textalpha. As expected, stable NKP6.3 expression markedly reduced IL-6, IL-8 and TNF-\textalpha mRNA expression (Supplementary Figure S2), indicating that NKP6.3 inhibits DNMT1 activity by down-regulating NF-kB activity at the transcriptional level.

Hace1 regulates NF-kB expression and activity. Next, we determined the regulatory role of Hace1 in NF-kB expression. As shown in Figure 5A–D, silencing of Hace1 with \textit{siHace1} increased expression of p65, p50 and DNMT1 at the mRNA and protein levels in NKP6.3 stable transfectants. In addition, DNMT1 activity was also increased in \textit{siHace1} transfected AGS\textsubscript{NKP6.3} and MKN1\textsubscript{NKP6.3} cells (Fig. 5E), suggesting that Hace1 is involved in NF-kB inactivation.

\textit{H. pylori} CagA is an important factor for ROS production. Here, we examined the effects of \textit{H. pylori} CagA on ROS production and expression of ROS-related genes. Expectedly, CagA significantly increased cell growth and ROS production in AGS and MKN1 cells, whereas NKP6.3 ablated the effects of CagA (Fig. 6A–C). To further confirm that CagA induces ROS production, we examined ROS levels in AGS cells by using the strain of \textit{H. pylori} with or without CagA. As shown in Figure 6D, \textit{H. pylori} with CagA significantly increased ROS production, whereas \textit{H. pylori} without CagA did not affect ROS levels in AGS cells. Additionally, CagA increased the expression of NF-kB p65, p50 and DNMT1 proteins and induced loss of Hace1 expression, whereas NKP6.3 markedly inhibited CagA effects on protein expression (Fig. 6E). Furthermore, NKP6.3 suppressed CagA-induced DNMT1
Figure 1. NKX6.3 reduces ROS levels by regulating ROS-responsive genes. (A–C) Measurement of ROS using Fluorescence microscopy and FACS analysis by DCFDA staining. Stable expression of NKX6.3 in AGS and MKN1 cells showed reduced levels of ROS in a time-dependent manner, compared to mock stable AGS and MKN1 cells. Results are represented as mean ± SEM from three independent experiments. (D) NKX6.3 significantly induced the expression of Hace1, Nrf2, catalase and mnSOD, and reduced the expression of Nox1 and Noxa1 proteins in western blot assay. (E) In real-time PCR analysis, NKX6.3 induced GSH, Nqo-1 and Ho-1 mRNA transcript. Results are represented as mean ± SEM from three independent experiments. Each dot plot represents the result from the individual experiment. ***P < 0.0001, *P < 0.05, based on the student’s t-test.
Figure 2. NKX6.3 increases Hace1 expression by inducing demethylation of Hace1 promoter. (A) In DCFDA staining analysis, knock-down of Hace1 partially recovered ROS production in NKX6.3 stable cells. Results are represented as mean ± SEM from three independent experiments. (B) In NKX6.3 stable cells, knock-down of Hace1 reduced Nrf2 expression in western blot analysis. (C) In real-time PCR analysis, Hace1 silencing resulted in decreased GSH, Nqo1 and Ho-1 mRNA expression in NKX6.3 stable cells. Results are represented as mean ± SEM from three independent experiments. (D) NKX6.3 stable cells showed time-dependent inhibition of cell viability, but knock-down of Hace1 in NKX6.3 stable cells showed recovery of cell viability. Results are represented as mean ± SEM from three independent experiments. (E) NKX6.3 induced the expression of Hace1 mRNA transcript in AGS and MKN1 cells in real-time PCR. Results are represented as mean ± SEM from three independent experiments. (F) Hypermethylation of CpG island at Hace1 promoter was found in mock stable AGS and MKN1 cells, whereas NKX6.3 expression induced demethylation of Hace1 promoter in MSP and real-time qPCR. Results are represented as mean ± SEM from three independent experiments. Each dot plot represents the result from the individual experiment. **P < 0.01, *P < 0.05, based on the student’s t-test.
Figure 3. NKX6.3 inhibits the expression and activity of DNMT1. (A) NKX6.3 reduced DNMT1 mRNA and protein expression in AGS and MKN1 cells. (B) Inactivation of NF-κB significantly decreased DNMT1 mRNA and protein expression in AGS and MKN1 cells. (C) In ChIP assay, NKX6.3 inhibited p50 binding to the promoter region of DNMT1 gene and its inhibitory effect was very similar to that of siNF-κB. Collagen gene was used as a negative control and bands were seen in the input but not in the IgG and p50 precipitated genomic DNA. (D) NKX6.3 expression and NF-κB silencing significantly reduced DNMT1 activity. (E) Inactivation of DNMT1 with shDNMT1 induced Hace1 mRNA and protein expression. (F) DNMT1 silencing induced de-methylation of Hace1 promoter. All results are represented as mean ± SEM from three independent experiments. Each dot plot represents the result from the individual experiment. **P < 0.01, *P < 0.05, based on the student’s t-test.
expression and hypermethylation of Hace1 gene in AGSNKX6.3 and MKN1 NKX6.3 cells (Fig. 6F, G). Our data suggest that NKX6.3 inactivates stimulatory effects of CagA on cell growth, ROS production, NF-κB signaling pathway, and DNMT1 activity in gastric epithelial cells.

Expression of NKX6.3, Hace1, and DNMT1 is closely associated in gastric mucosae and cancers. In 65 gastric cancer tissues, DNMT1 expression was significantly increased, whereas Hace1 expression was significantly reduced (Fig. 7A and B). NKX6.3 and Hace1 expression were positively correlated, while DNMT1 expression was inversely correlated with NKX6.3 and Hace1 expression in gastric cancer tissues (Fig. 7C–E). Consistently, NKX6.3, Hace1, and Nrf2 expression was reduced and showed positive correlation in...
In 55 non-neoplastic gastric mucosae, DNMT1 and Hace1 expression was increased and reduced, respectively, in gastric mucosae with *H. pylori* infection, atrophy and intestinal metaplasia (Fig. 7F and G). Non-neoplastic gastric mucosae also showed positive correlation between NKX6.3 and Hace1 expression and inverse correlation between DNMT1 and NKX6.3 expression (Fig. 7H and I). The methylation status of Hace1 promoter region was examined by MSP to confirm that reduced Hace1 mRNA expression in gastric mucosae is caused by hypermethylation of Hace1. Interestingly, Hace1 hypermethylation was observed only in the gastric mucosa with *H. pylori* infection, atrophy, and/or intestinal metaplasia (Fig. 7J), suggesting that NF-kB-induced DNMT1 expression caused by NKX6.3 inactivation may reduce Hace1 expression by hypermethylation the promoter region of Hace1 in the gastric mucosa.

**Discussion**

Gastric cancers develop as a consequence of chronic inflammation from persistent mucosal or epithelial cell colonization by microorganisms, including *H. pylori*. Chronic inflammatory cells such as macrophages/monocytes, lymphocytes, and plasma cells are present in the gastric mucosa of chronic gastritis and lead to the generation of several ROS and RNS. Persistent ROS can damage cellular DNA, RNA, and proteins by chemical reactions, which subsequently cause proto-oncogene activation, oncogene/tumor suppressor gene mutations, and chromosomal aberrations. In stomach, *H. pylori* and ROS collaborate in the gastric epithelium to activate the NF-κB and AP-1 transcription factors that up-regulate the expression of chemokines, including IL-8, and in turn, NF-κB-dependent genes play a major role in regulating the cellular ROS levels. Recently, we and others reported

---

**Figure 5.** Knock-down of Hace1 induces NF-κB expression and activity. (A–C) Knock-down of Hace1 in NKX6.3 stable cells induced expression of NF-κB p65 (A), p50 (B) and DNMT1 (C) mRNA transcript in real-time PCR analysis. Results are represented as mean ± SEM from three independent experiments. (D) In NKX6.3 stable cells, silencing of Hace1 with siHace1 increased NF-κB p65, p50 and DNMT1 protein expression. (E) Knock-down of Hace1 induced DNMT1 activity in NKX6.3 stable cells. Results are represented as mean ± SEM from three independent experiments. Each dot plot represents the result from the individual experiment. *P < 0.05, based on the student’s t-test.
Figure 6. NKX6.3 suppresses the effects of *H. pylori* CagA on cell growth, ROS production, NF-κB signaling pathway and DNMT1 activity. (A and B) CagA induced a time-dependent increase in cell viability (A) and cell proliferation (B), but the expression of NKX6.3 inhibited the stimulatory effects of CagA on cell viability and proliferation. Results are represented as mean ± SEM from three independent experiments. (C) NKX6.3 abrogated CagA-induced ROS production in NKX6.3 stable cells. (D) CagA increased the expression of NF-κB p65, p50 and DNMT1 proteins and induced loss of Hace1 expression, but NKX6.3 markedly inhibited the CagA effects on expression of these proteins. (E) CagA enhanced DNMT1 activity in AGS and MKN1 cells, but NKX6.3 suppressed the CagA-induced DNMT1 activity. Results are represented as mean ± SEM from three independent experiments. (F) NKX6.3 inhibited CagA-induced hypermethylation of *Hace1* gene. Each dot plot represents the result from the individual experiment. **P < 0.005, *P < 0.05, based on the student’s t-test.
Figure 7. NKX6.3 is correlated with DNMT1 and Hace1 in gastric mucosae and gastric cancer tissues. (A and B) The relative mRNA expression levels of DNMT1 (A) and Hace1 (B) in noncancerous (Normal) and gastric cancer (Tumor) tissues are illustrated by scatterplot. The median expression level of each group is indicated by horizontal line. (C–E) A positive correlation of NKX6.3 with Hace1 and inverse correlation of DNMT1 expression with NKX6.3 and Hace1 expression. (F and G) Expression levels of DNMT1 (F) and Hace1 (G) in 55 gastric mucosae with *H. pylori* infection, atrophy and intestinal metaplasia. (H and I) A positive correlation between NKX6.3 and Hace1 expression and inverse correlation between DNMT1 and NKX6.3 expression in non-neoplastic gastric mucosae. (J) Methylation status of Hace1 promoter region examined by MSP. Hypermethylation of Hace1 gene was observed only in the gastric mucosae with *H. pylori* infection, atrophy, and/or intestinal metaplasia. ***P < 0.001, **P < 0.005, based on the two-way ANOVA, linear progression and Chi-square tests.
that NKX6.3 acts as a master regulator in gastric differentiation and proliferation\(^{12-14}\). Since the gastric mucosal barrier may protect the host from potentially harmful agents to maintain cell survival, we focused on the role of NKX6.3 in the protection of the gastric mucosal epithelia from harmful ROS.

It is well known that Hac1 functions as an important component of the cellular ROS detoxification and anti-oxidative stress responses by facilitating optimal activation of Nrf2\(^{27}\). Here, we showed that NKX6.3 reduced intracellular ROS and modulated the expression of ROS-related genes (Fig. 1). Of these, NKX6.3 induced expression of Hac1 and Nrf2 proteins in gastric cancer cells (Fig. 1D) and showed positive correlation with Hac1 and Nrf2 in the gastric cancer cohort (Supplementary Figure S1). In addition, Hac1 silencing with siHac1 recovered ROS production and reduced Nrf2, GSH, Nqo and Ho-1 expression (Fig. 2A–C). Furthermore, knock-down of Hac1 ablated NKX6.3-induced cell growth inhibitory activity (Fig. 2D). Taken together, these results suggest that NKX6.3 plays an important role in suppression of ROS production by regulating expression of ROS-related genes, especially Hac1.

NKX6.3 increased Hac1 expression and was positively correlated with Hac1, suggestive of direct regulation of Hac1 expression. Since Hac1 expression is significantly reduced by promoter hypermethylation in most cancer patients\(^{47}\), we investigated whether DNMT1 regulates Hac1 expression in gastric epithelial cells. NF-κB reportedly binds to one possible NF-κB binding element in the DNMT1 promoter and DNMT1 mediates NF-κB-dependent p16 gene promoter hypermethylation\(^{35}\). Here, we showed that NKX6.3 induced Hac1 promoter demethylation and increased its expression (Fig. 2E and F) by down-regulating DNMT1 expression via inhibiting p50 binding in the promoter region of DNMT1 gene (Fig. 3C). In addition, the effect of NKX6.3 on DNMT1 activity was comparable with that of siNF-κB treatment (Fig. 3D). Furthermore, DNMT1 silencing with siDNMT1 led to demethylation of Hac1 and increased its expression at the mRNA and protein levels (Fig. 3E and F). These results suggest that NKX6.3 induces Hac1 expression by inhibiting DNMT1 expression and activity.

Next, we investigated whether NKX6.3 regulates NF-κB, which is constitutively activated in most cancers\(^{28}\). NF-κB consists of a family of transcription factors, including p65 (RelA), p50 (RelB), c-Rel, p105/p50 (NF-κB1), and p100/p52 (NF-κB2), which play critical roles in inflammation, immunity, cell proliferation and survival\(^{29}\). The amino-terminus of the Rel homology domain in p50 homo- and p50/p65 heterodimers mediates specific DNA binding to the NF-κB consensus sequence present in regulatory elements of NF-κB target genes\(^{30-32}\). NKX6.3 significantly reduced p65 and p50 expression at the mRNA and protein levels (Fig. 4A–C). In particular, the promoter regions of p65 and p50 have 6 and 5 NKX6.3 candidate binding sites, respectively (Fig. 4D), and the binding activity of NKX6.3 to these regions was confirmed in ChIP analysis (Fig. 4E). In addition, NKX6.3 markedly reduced the expression of NF-κB target genes including IL-6, IL-8 and TNF-α (Supplementary Figure S2).

In addition, silencing of Hac1 with siHac1 increased the expression of p65, p50 and DNMT1 and activity of DNMT1 (Fig. 5). Thus, these data indicate that NKX6.3 and Hac1 negatively control NF-κB expression and activity.

It has been reported that H. pylori induces the production of ROS and DNA damage in gastric epithelial cells and frequently causes chromosomal aberrations\(^{33,34}\). Previously, we showed that H. pylori CagA increased the expression of NF-κB proteins and ROS levels in gastric cancer cells\(^{35}\). In the current study, CagA significantly increased cell growth and ROS production in AGS\(^{36}\), MKN1\(^{37}\) and MKN1\(^{38}\) cells, whereas NKX6.3 ablated these CagA effects by down-regulating NF-κB p65, p50 and DNMT1 and up-regulating Hac1 expression (Fig. 6A–F). These findings suggest that NKX6.3 may counteract CagA-induced NF-κB activity in gastric epithelial cells.

Damage to cellular components results in increased mutations and altered functions of important proteins in premalignant tissues, thereby contributing to the multi-stage carcinogenesis\(^{36}\). Chronic inflammation of gastric mucosa triggers a pathway of chronic gastritis, atrophy, intestinal metaplasia, dysplasia, which finally progress to gastric cancer\(^{37}\). H. pylori, especially CagA strains, is considered as the most important risk factor of atrophy and intestinal metaplasia\(^{38,39}\). In gastric cancer tissue, NKX6.3 and Hac1 expression showed a positive correlation, while DNMT1 expression was inversely correlated with NKX6.3 and Hac1 (Fig. 7A–E). The NCBI GEO database also showed reduced NKX6.3, Hac1 and Nrf2 expression and a positive correlation between these genes (Supplementary Figure S1). In non-neoplastic gastric mucosa of H. pylori infection, atrophy and intestinal metaplasia, DNMT1 mRNA was increased, whereas Hac1 mRNA was reduced. (Fig. 7F and G). NKX6.3 expression was positively and inversely correlated with Hac1 and DNMT1, respectively (Figure H and I). Interestingly, Hac1 hypermethylation was observed only in the gastric mucosa with H. pylori infection, atrophy, and/or intestinal metaplasia (Fig. 7J). Thus, NKX6.3 inactivation in gastric mucosa may increase activity of NF-κB and DNMT1 and reduce Hac1 expression, subsequently progressing to atrophy, intestinal metaplasia and cancer.

In conclusion, NKX6.3 induced Hac1 expression by suppressing DNMT1 expression and activity via down-regulating the NF-κB signaling pathway. In addition, NKX6.3 ablated CagA effects on cell proliferation, ROS production, and activities of DNMT1 and NF-κB signaling pathway. Overall, we conclude that NKX6.3 protects gastric mucosal epithelia by regulating harmful ROS production. Modulation of NKX6.3 anti-oxidant activity could contribute to the prevention of precancerous changes in gastric mucosa and gastric cancer.

**Materials and Methods**

**Cell culture and generation of NKX6.3 stable cells.** AGS and MKN1 gastric cancer cell lines were cultured at 37°C in 5% CO\(_2\) in RPMI-1640 medium (Lonza, Basel, Switzerland) with 10% heat-inactivated fetal bovine serum (FBS). NKX6.3 and CagA cDNAs were cloned into the pcDNA3.1 expression vectors (Invitrogen, Carlsbad, CA, USA) and siHACE1, siDNMT1, and siNF-κB were cloned into pSilencer neo vectors (Invitrogen, Carlsbad, CA, USA). We generated stable NKX6.3 transfectants of AGS and MKN1 cells, AGS\(^{\text{NKX6.3}}\) and MKN1\(^{\text{NKX6.3}}\), stably expressing human NKX6.3, as well as mock transfectants, AGS\(^{\text{Mock}}\) and MKN1\(^{\text{Mock}}\) cells, as described previously\(^{33}\). AGS\(^{\text{NKX6.3}}\) and MKN1\(^{\text{NKX6.3}}\) cells were transfected in 60 mm-diameter dishes with the expression plasmids (2 μg total DNA) using Lipofectamine Plus transfection reagent (Invitrogen) according to
the manufacturer’s recommendations. Stable expression of NNX6.3 was confirmed in AGSNNX6.3 and MKN1NNX6.3 cells by western blot analysis.

**Gastric mucosa and cancer tissue specimens.** A total of 65 patients with sporadic gastric cancer who underwent a gastrectomy at the Chonnam National University Hwasun Hospital were enrolled. In addition, a total of 55 non-neoplastic frozen gastric mucosa remote (>5 cm) from gastric cancer were included in this study. Adjacent gastric mucosal tissues to each frozen specimen were also fixed in formalin and stained with hematoxylin-eosin. Informed consent was provided according to the Declaration of Helsinki. Written informed consent was obtained from all subjects. The study was approved by the Institutional Review Board of The Catholic University of Korea, College of Medicine (MC15SISI0015). There was no evidence of familial cancer in any of the patients.

Histological assessment of 55 non-neoplastic gastric mucosae was performed independently by two pathologists. According to the updated Sydney system40,41, gastritis was determined by polymorphonuclear leukocyte infiltration, mononuclear cell infiltration, glandular atrophy and intestinal metaplasia, as previously described14. Infection with a CagA-positive strain of *H. pylori* was determined by the presence of CagA protein in 55 gastric mucosa tissue samples using western blot analysis, as described previously15.

**Measurement of cell viability and proliferation.** Cell viability was determined in AGS and MKN1 gastric cancer cells after treatment with siHace1 or *H. pylori* CagA transfection. To assess cell viability, a MTT [3(4,5-dimethylthiazol-2-yl)–2,5-diphenyltetrazoliumbromide] assay was performed at 24, 48, 72, and 96 hrs following transfection with siHace1 and CagA in mock, AGSmock and MKN1mock cells, and NNX6.3 stable transfectants, AGSNNX6.3 and MKN1NNX6.3 cells. Absorbance was measured at 540 nm using a spectrophotometer and viability was expressed relative to the mock control.

For cell proliferation assay, a BrdU incorporation assay was performed at 24, 48, 72, and 96 hrs following transfection with CagA in mock and NNX6.3 stable cells using the BrdU cell proliferation assay kit (Millipore, Billerica, MA, USA), according to the manufacturer’s instruction. Absorbance was measured using a spectrophotometer at 450 nm and proliferation was expressed relative to the mock control.

**Expression of ROS-related genes in gastric cancer cell lines and tissues.** Expression of NNX6.3, Hace1, and DNTM1 was examined in 65 frozen gastric cancers, corresponding non-cancerous gastric mucosal tissues, and 2 gastric cancer cell lines by real-time RT-PCR and Western blot analysis. After quantification of mRNA extracted from cancer tissues and non-cancerous gastric mucosae, cDNA was synthesized using the reverse transcription kit from Roche Molecular System (Roche, Mannheim, Germany), according to the manufacturer’s protocol. For QPCR, 50 ng cDNA was amplified using Fullvelocity SYBR Green QPCR Master Mix (Stratagene, La Jolla, CA, USA) and 20 pmol/l of each primer (forward and reverse) using Stratagene Mx 3000 P QPCR system, according techniques previously published19. NNX6.3, Hace1, and DNTM1 mRNAs were quantified by SYBR Green Q-PCR and normalized to mRNA of the β-actin. Sequences of the primers are described in Supplementary Table S1. Data are reported as relative quantities according to an internal calibrator using the 2-△△CT method42. All samples were tested in duplicate, and the mean values were used for quantification. In addition, the relation between expression levels of ROS-related genes and gastritis parameters, such as atrophy, intestinal metaplasia and *H. pylori* infection was also examined in 55 non-neoplastic gastric mucosae.

To investigate whether ablation of NNX6.3 is associated with ROS production, the expression of NF-κB, Hace1, DNTM1, GSH, Nqo1, and Ho-1 mRNA were analyzed using real-time RT-PCR in AGSmock, MKN1mock, AGSNNX6.3, and MKN1NNX6.3 cells. The effects of Hace1 silencing with siHace1 on the expression of ROS-related genes were also examined. To further confirm that NNX6.3 regulates NF-κB activity, we analyzed mRNA transcript expression of IL-6, IL-8, and TNF-α, which are downstream targets of the NF-κB43. Each mRNA was quantified by SYBR Green QPCR and normalized to mRNA of the housekeeping gene, β-actin. The primer sequences are described in Supplementary Table S1.

For Western blot analysis, the samples were ground to very fine powder in liquid nitrogen using a pestle and mortar, suspended in an ice-cold Nonidet P-40 lysis buffer supplemented with 1x protease inhibitor mix (Roche). Cell lysates were separated on 10% polyacrylamide gel and blotted onto a Hybond-PVDF transfer membrane (Amersham), which had been subsequently probed with specific antibodies, and then incubated with anti-mouse IgG conjugated with horseradish peroxidase. The list of antibodies is described in Supplementary Section.

**Methylation status of Hace1.** Methylation analysis was carried out in 55 frozen non-neoplastic gastric mucosae and 2 gastric cancer cell lines after transfection with NNX6.3. Methylation status of the promoter region of the Hace1 gene was determined using sodium bisulfite treatment of the DNA followed methylation specific PCR (MSP), as described in the literature with minor modifications37. 5 μl of the bisulfite-modified DNA was subjected to MSP using two sets of primers for methylated and unmethylated Hace1. The primer sequences are described in Supplementary Table S1. PCR was performed in a total volume of 30 μl containing 5 μl of the template DNA, 0.5 μM of each primer, 0.2 μM of each dNTP, 1.5 mM MgCl2, 0.4 unit of Ampli Tag gold polymerase (Perkin-Elmer) and 3 μl of 10X buffer. The reaction solution was initially denatured for 1 min at 95 °C. Amplification was carried out for 40 cycles of 30 s at 95 °C, 30 s at 58 °C and 30 s at 72 °C, followed by a final 5 min extension at 72 °C. Each PCR product was loaded directly onto 2% agarose gels, stained with ethidium bromide and visualized under UV illumination.

**Generation of CagA gene deleted H. pylori strains.** The isogenic mutant *H. pylori* 26695 (AcagA:aphA), in which most of the cagA gene was replaced by a aphA (kanamycin resistant gene from pIP1433)
Reactive oxygen species (ROS) analysis. ROS levels were determined in mock or NKK6.3 stable AGS and MNK1 cells using 2′,7′-dichlorodihydrofluorescein diacetate (DCFDA). The AGS and MNK1 cells were incubated with 10 μM DCFDA at 37 °C for 20 min and rinsed twice with cold PBS, then trypsinized and subjected to FACScan flow cytometer. To determine the effects of H. pylori CagA on ROS production, the ROS levels were examined in H. pylori with/without CagA-infected AGS cells at 12 hrs as well as in mock and NKK6.3 stable AGS and MNK1 cells at 72 hrs after transfection with H. pylori CagA. DCF fluorescence was measured by FACs analysis and intensity was plotted against the number of cells. Additionally, cells were incubated with 10 μM DCFDA at 37 °C for 20 min and quickly washed with cold PBS, and photos of representative fluorescent fields were taken under an inverted microscope.

Chromatin immunoprecipitation (ChIP) analysis. For assessing the NKK6.3 binding activity in the promoter region of NF-κB p65 and p50, ChIP assays were performed using the Thermofisher Scientific Agarose ChIP kit (Thermofisher Scientific, Rockford, IL, USA), as previously described. Briefly, AGS mock, MNK1 mock, AGSNKK6.3 and MNK1NKK6.3 cells were cultured in a 10-cm dish for 4 days. The cells were fixed with 1% formaldehyde in PBS for 10 min, washed twice with ice-cold PBS and re-suspended in lysis buffer. Nuclei were recovered by centrifugation and Mase digestion was carried out at 37 °C for 15 min. Nuclei were lysed and the extracts were immunoprecipitated with 4 μg of antibody against NKK6.3 at 4 °C overnight. Normal rabbit IgG was used as the negative control. Protein-bound DNA was recovered using affinity chromatography purification columns according to the manufacturer’s protocol (Thermofisher Scientific), and 5 µl of lysed nuclei were also purified under the same procedure and used as input. DNA amplification was performed by PCR using specific primers for the promoters of NF-κB p65, p50 and DNMT1 genes, as described in Supplementary Table S1. Amplification products were separated on a 2% agarose gel.

Measurement of DNMT1 activity. The DNMT1 activity was analyzed using the DNMT1 activity assay kit (Abcam) according to manufacturer’s instructions. Briefly, AGS and MNK1 cells were collected and suspended in PBS. After centrifugation, the pellet was lysed in lysis buffer (10 mM Tris-Hcl pH 7.5, 10 mM NaCl, 2 mM MgCl2) containing protease inhibitor mixture (Complete; Roche Molecular Biochemicals). Then, 6 µl of lysed nuclei were also purified under the same procedure and used as input. DNA amplification was performed by PCR using specific primers for the promoters of NF-κB p65, p50 and DNMT1 genes, as described in Supplementary Table S1. Amplification products were separated on a 2% agarose gel.

Statistical analysis. Student’s t-test was used to analyze the effects of NKK6.3 on cellular ROS levels, cell viability and mRNA expression changes. Two-way ANOVA test was used to analyze the expression of DNMT1 and HACE1 in normal gastric mucosae and gastric cancer tissues. Linear progression test was used to analyze correlation between DNMT1, HACE1 and NKK6.3 expression levels in normal gastric mucosae and gastric cancer tissues. Chi-square test was used to analyze correlations between H. pylori CagA, atrophy, intestinal metaplasia and methylation status of the HACE1 promoter. Data are expressed as means ± S.D. from at least three independent experiments. A P-value less than 0.05 was considered to be the limit of statistical significance. All experiments were performed in triplicate to verify the reproducibility of the findings.
