Medullary thyroid carcinoma: Management and complexities of postoperative follow-up

Mirza Faraz Saeed, Nida Fatima Sakrani, Isam Mazin Juma, Abbas Ali

ABSTRACT

Introduction: Medullary thyroid cancer is one of the less common types of thyroid malignancies as compared to the more frequent papillary and follicular types and constitutes 4% of thyroid cancer. Serum tumors markers are a significant part of diagnosis and postoperative follow-up. Although calcitonin is an apparent marker, levels of carcinoembryonic antigen (CEA) can also be used. In patients that are surgically managed, calcitonin levels can begin to rapidly decline within the first postoperative hour.

Case Report: This paper presents a case of 37-year-old Indian female treated for medullary thyroid carcinoma and followed-up over a year. Fine-needle aspiration cytology (FNAC) biopsy was reported as highly suspicious of malignancy. The patient underwent a near total thyroidectomy and the following histopathology report confirmed medullary carcinoma.

Conclusion: This paper highlights the importance of biochemical follow-up of calcitonin level, following surgical resection in cases of medullary thyroid carcinoma as a part of postoperative care.

INTRODUCTION

The thyroid tissue is known to be one of the most radiation-sensitive tissues in the body, with excess cancers occurring at doses as low as 100 mGy [1, 2]. Of note, American statistics report that medical radiation accounts for nearly half of the radiation exposure experienced by the population [2]. Medullary thyroid cancer is one of the less common types of thyroid malignancies as compared to the more frequent papillary and follicular types [3] and constitutes 4% of thyroid cancer [1]. Chances of survival are much improved and notably optimistic when the malignancy is detected early.

This subtype of cancer is a neuroendocrine tumor and comprises the parafollicular C cells. The malignant C cells release an increased level of calcitonin that is medically useful as a tumor marker used in diagnosis and follow-up.
Medullary cancer is infamous due to its involvement in the multiple endocrine neoplasia type 2 (MEN2) syndromes. However, the sporadic, nonhereditary type is actually responsible for 80% of cases [1]. The tumor can present as a neck mass and this is most common, or with symptoms pertaining to increased hormone levels similar to other tumors composed of neural crest cells. Tumor secretion of calcitonin, calcitonin gene related peptide can cause diarrhea or facial flushing in patients with advanced disease, while occasionally the secretion of ACTH (corticotropin) can manifest as Cushing’s syndrome [1]. When present as part of the MEN2 combination the patient may suffer accordingly with hyperparathyroidism, a pheochromocytoma or a marfanoid habitus, mucosal neuromas, and intestinal ganglioneuromatosis [1].

This report pertains to a case of early stage medullary thyroid carcinoma that developed in a lady with previous radiation exposure and was successfully operated upon. In this discussion, we dissect the process of postoperative follow-up and the dilemma of the increasing tumor marker, calcitonin following such definitive treatment.

**CASE REPORT**

A 37-year-old Indian female nurse, with a five-year history of without any radiation exposure while working as orthopedic surgical staff, presented to our surgical clinic in July 2012 with a self-discovered nodule in the right lobe of her thyroid gland. Further questioning revealed weight loss, a history of gestational hypothyroidism treated with levothyroxine and a significant family history with a father currently in remission after treatment for an oropharyngeal malignancy.

Following appropriate examination, appropriate investigations were undertaken including a fine-needle aspiration cytology (FNAC) biopsy. The FNAC was reported as highly suspicious of malignancy. FNAC features showed several small and large clusters of elongated spindle-shaped cells. Hyperchromatic, pleomorphic nuclei with scant cytoplasm. Glassy pink amyloid-like material was also present, suggestive of medullary thyroid carcinoma. Consequently, the patient underwent a near total thyroidectomy on 24th July 2012 and the histopathological diagnosis confirmed our suspicions of malignancy and further diagnosed a containing medullary carcinoma, staged as T1N0M0 with no nodular involvement. Computer tomography scans of the chest, abdomen and pelvis were done after the surgery ruled out any metastasis.

Between 2013 and 2014, the patient was seen at regular follow-up visits and neck ultrasounds, as well as calcitonin and CEA levels were repeated. The increasing size of the small residual thyroid tissue left from 1 cm in 2013 to 1.8 in 2014 was noted along with rising CEA and calcitonin levels as depicted in the (Figure 1 and Figure 2).

**DISCUSSION**

**Initial Steps**

Multiple sources list the same process of diagnosis as was followed by our team which comprises clinical examination, followed by a neck ultrasound and fine needle aspiration. There is controversy regarding the use of calcitonin measurement when there is a high suspicion and is not carried out in the United States because of the high frequency of falsely high serum calcitonin values and the accuracy of FNAC [1]. Sonographic imaging is used to determine lymph node metastasis, and when detected then further imaging is used to stage the tumor. Imaging techniques include neck computed tomography (CT), chest CT, tri-phasic liver CT with contrast or liver magnetic resonance imaging (MRI) with contrast [1].

Following pathological confirmation, serum tumor markers become significant, and while calcitonin is the apparent one, carcinoembryonic antigen (CEA) is also of significance. Advanced imaging techniques discussed above are also to be employed when the basal preoperative calcitonin level is >400 pg/mL since this implies a high risk of metastatic disease [1]. Postoperatively, these results allow the clinician to decide on the prognosis and postoperatively indicate biochemical cure.

To complete the process, the patient must be screened for the other manifestations of the MEN2 syndromes with measurement of calcium levels for hyperparathyroidism and plasma fractionated
metanephrines for pheochromocytoma, 4-urinary fractionated metanephrines and catecholamine’s [1, 4]. Appropriate imaging can be additionally used if any of these are suspected.

As with all neoplasms treatment varies according to the stage of disease. Table 1 gives the details on the TNM staging adopted by The Union for International Cancer Control (UICC) and the American Joint Committee on Cancer (AJCC) [1]. Our patient was classified as Stage 2 and the optimum treatment was offered through a subtotal thyroidectomy.

**The Evasiveness of Follow-Up**

The case reported presents the question of when a postoperative rise in calcitonin should be considered as significant and when to provide further treatment. It is important to note that there are alternative causes for a rise in calcitonin. False-positive calcitonin results may be obtained in patients with hypercalcemia, hypergastrinemia, neuroendocrine tumors, renal insufficiency, papillary and follicular thyroid carcinomas, goiter, and chronic autoimmune thyroiditis [5]. Drugs that can cause a false positive result include omeprazole, beta blockers and glucocorticoids [5].

Kebebew et al, followed a 104 patients over an average of eight years and found through multivariate analysis that age and stage of disease are independent prognostic factors, meaning that younger age and an earlier stage of disease allow greater survival [6]. Pelizzo discovered the same after a 37-year follow-up of a 157 patients but also add extent of surgery as a prognostic factor [7]. This implies that a more advanced tumor requires more extensive surgery and both relate to poor prognosis. Furthermore, Kebebew et al., report that patients with postoperative hypercalcitoninemia without clinical or radiologic evidence of residual tumor after apparently curative surgery may enjoy long term survival, but elevated calcitonin can be attributed to occult disease [6].

The recommended method of postoperative follow-up is through measurement of serum calcitonin and CEA after two to six months, and normal serum level of these hormones indicates a biochemical cure [4, 8]. Successful surgery and a biochemical cure have been associated, with less than 4% risk of recurrence during follow-up [3]. In patients that are surgically cured, calcitonin levels begin to rapidly decline within the first postoperative hour [8]. However, it is important to correctly time the measurement since calcitonin levels in some patients can sometimes take several months to normalize [8].

If a high calcitonin level is detected six or more months following surgery than residual disease should be suspected [8]. However, considering the risks and difficulty of further and sometimes-radical neck surgery, it is then required to decide the degree of residual disease. Calcitonin values which are detectable but less than 150 pg/mL indicate persistent loco-regional disease in the neck [8]. To locate this disease, neck ultrasound and further imaging including CT scan and MRI scan should be used [8]. High-resolution ultrasonography is preferred because it is noninvasive, sensitive, and relatively inexpensive, and moreover, it can be used in acquiring a cytological diagnosis through FNAC [4].

It is recommended that in non-specialized institutions, only cases of overt disease without metastasis should undergo neck surgery [8]. If, on the other hand, macroscopic disease is not found through imaging and the calcitonin level remains constant then annual follow-up is required. This is done through a neck ultrasound and calcitonin measurement at sixth month intervals, with particular emphasis on determining the doubling time, which is a strong indicator of survival [3, 4]. The American thyroid association states that when there is no anatomic evidence of disease, despite detectable serum creatinine, the best option is observation [4]. Furthermore it recommends that, in the case of nonhazardous loco-regional disease, immediate intervention is of unknown benefit and such lymph nodes may be observed or undergo re-operative compartmental dissection of image or biopsy-positive compartments [4]. Further when calcitonin levels are higher than 150 pg/mL, distant metastasis is more likely and extensive imaging including neck and chest CT scan, liver MRI scan, bone scan, spine and pelvis MRI scans or PET/CT scan are required [4]. Although it is not the focus of this report, a brief mention regarding the treatment options for metastatic disease is necessary. Palliative treatments include surgery, hepatic embolization, external beam radiation therapy, and percutaneous interventions. Active treatment is recommended for lesions in vital locations, such as brain metastases, impending or active central nervous system compression, airway compromise, symptomatic lesions, hormonal secretion, and impending or active fracture of a weight bearing bone [4]. The management of patients with metastatic disease outside the neck remains controversial [9].

---

**Table 1: Pathological TNM criteria**

| Stage | Description |
|-------|-------------|
| STAGE 1 | Less than 2 cm in diameter without evidence of disease outside of the thyroid gland. |
| STAGE 2 | Between 2 and 4 cm without evidence of extra thyroidal disease. |
| STAGE 3 | Greater than 4 cm, or level VI nodal metastases or microscopic extra thyroidal invasion regardless of tumor size. |
| STAGE 4 | Any distant metastases, or lymph node involvement outside of level VI, or gross soft tissue extension. |
CONCLUSION

Postoperative follow-up and further management consist of measuring calcitonin levels, with the key number being at 150 pg/ml. Elevated biochemical levels of calcitonin should be correlated with evidence of macroscopic disease. Further management would range from follow-up in cases of elevated biochemical levels only to implementation of palliative care in cases of evidences of metastatic disease in addition raised calcitonin levels.

Edorium Journals: An introduction

Edorium Journals Team

About Edorium Journals
Edorium Journals is a publisher of high-quality, open access, international scholarly journals covering subjects in basic sciences and clinical specialties and subspecialties.

Invitation for article submission
We sincerely invite you to submit your valuable research for publication to Edorium Journals.

But why should you publish with Edorium Journals?
In less than 10 words - we give you what no one does.

Vision of being the best
We have the vision of making our journals the best and the most authoritative journals in their respective specialties. We are working towards this goal every day of every week of every month of every year.

Exceptional services
We care for you, your work and your time. Our efficient, personalized and courteous services are a testimony to this.

Editorial Review
All manuscripts submitted to Edorium Journals undergo pre-processing review, first editorial review, peer review, second editorial review and finally third editorial review.

Peer Review
All manuscripts submitted to Edorium Journals undergo anonymous, double-blind, external peer review.

Early View version
Early View version of your manuscript will be published in the journal within 72 hours of final acceptance.

Manuscript status
From submission to publication of your article you will get regular updates (minimum six times) about status of your manuscripts directly in your email.

Our Commitment

Six weeks
You will get first decision on your manuscript within six weeks (42 days) of submission. If we fail to honor this by even one day, we will publish your manuscript free of charge.*

Four weeks
After we receive page proofs, your manuscript will be published in the journal within four weeks (31 days). If we fail to honor this by even one day, we will publish your manuscript free of charge and refund you the full article publication charges you paid for your manuscript.*

Favored Author program
One email is all it takes to become our favored author. You will not only get fee waivers but also get information and insights about scholarly publishing.

Institutional Membership program
Join our Institutional Memberships program and help scholars from your institute make their research accessible to all and save thousands of dollars in fees make their research accessible to all.

Our presence
We have some of the best designed publication formats. Our websites are very user friendly and enable you to do your work very easily with no hassle.

Something more...
We request you to have a look at our website to know more about us and our services.

* Terms and condition apply. Please see Edorium Journals website for more information.

We welcome you to interact with us, share with us, join us and of course publish with us.
