Abstract
We study the similarity solutions and we determine the conservation laws of the various forms of beam equation, such as, Euler-Bernoulli, Rayleigh and Timoshenko-Prescott. The travelling-wave reduction leads to solvable fourth-order odes for all the forms. In addition, the reduction based on the scaling symmetry for the Euler-Bernoulli form leads to certain odes for which there exists zero symmetries. Therefore, we conduct the singularity analysis to ascertain the integrability. We study two reduced odes of order second and third. The reduced second-order ode is a perturbed form of Painlevé-Ince equation, which is integrable and the third-order ode falls into the category of equations studied by Chazy, Bureau and Cosgrove. Moreover, we derived the symmetries and its corresponding reductions and conservation laws for the forced form of the above mentioned beam forms. The Lie Algebra is mentioned explicitly for all the cases.

Keywords: Symmetry analysis; Singularity analysis; Conservation laws; Beam equation

1 Introduction
There are basically two type of beam. One type is supported at both ends and the other type is supported at one end only. It is a cantilever. The latter is of greater mathematical and physical interest for the free end can vibrate. This causes stresses in the beam. The first mathematical description was made by Leonhard Euler and Daniel Bernoulli around 1750, but there were some earlier attempts by Leonardo da Vinci and Galileo Galilei who were more than a little hampered by no knowledge of differential equations. Jacob Bernoulli laid the groundwork for the development of Leonhard Euler and Daniel Bernoulli. In 1894, the polymath Lord Rayleigh

proposed an improvement to the Euler-Bernoulli model by including a term related to rotational stress. In 1921, Timoshenko introduced considerable improvements in what is now termed the Timoshenko-Prescott model.

There has been considerable experimental and numerical work devoted to the comparison of predictions of the theories and experimental results. It should be emphasised that the infinitesimal theory of elasticity is three-dimensional and that the three models mentioned above are linear models. They make for easier mathematics, but there is a price to pay. Curiously the simplest model, that of Euler-Bernoulli, still finds favour amongst some practitioners.

Some of the experimental work [9] undertaken to compare reality with theoretical prediction tries to make the experiment as close to a one-dimensional model as is possible. One of the more interesting studies is the propagation of shock waves along the beam. This involves firing a bullet into the fixed end of the cantilever which is of slight diameter – 25 mm – to emulate a uniform boundary condition at the fixed end of the beam.

The literature devoted to the theory and practice of beams is extensive both in time and space. A fairly recent paper by Labuschagne [21] is very good in its historical aspects as well as being clearly written. Earlier papers in addition to that of Davies cited above are by Hudson [17] and Bancroft [4]. An interesting feature is that the beams are taken to be cylindrical in shape even though the beams one sees in buildings are anything but cylindrical with some exceptions to be found in beamed structures of the nineteenth century. One assumes that this makes the analysis simpler due to the radial symmetry. Even a square cross section would complicate the mathematics seriously.

In this work we study the algebraic properties of the Euler-Bernoulli, the Rayleigh and of the Timoshenko-Prescott according to the admitted Lie point symmetries, for the source-free equation as also in the case where a homogeneous source term exists. The application of symmetry analysis for the Euler-Bernoulli equation is not new, there are various studies in the literature [6, 12, 16, 29, 32], however in this paper, we obtained some new results, as the reduction of Euler-Bernoulli form to perturbed form of Painlevé-Ince equation, which is integrable and the third-order ode which falls into the category of equations studied by Chazy, Bureau and Cosgrove. Also, we show that the three beam equations of our study admit the same travelling-wave solution.

Certain phenomenal works were recently done for the static Euler-Bernoulli equation by Ruiz [28] and Da Silva PL [8]. In Ruiz [28] the Euler-Bernoulli equation with an external agent is studied with respect to the joint invariants of the algebra and complete solutions are specified whereas in [8] for the static Euler-Bernoulli equation with specific nonlinear term it was found that the algebraic structure of Lie point symmetries is similar to that of the Noether symmetries. It is worthwhile to mention the paper of Freire IL [13] where the Lane-Emden system is reduced to the Emden-Fowler equations and correspondingly the solutions of the system have been studied with the aid of the point symmetries. To elaborate the above mentioned works we focus on the more general Euler-Bernoulli equation with and without the external forcing term and compute its solution using the point symmetries. It is also our intuition that the point symmetries of the form of Euler-Bernoulli under consideration do possess some similarities with the Noether symmetries to follow the results of the above mentioned work.

This paper is structured as: In Section 2, we mention the Lie point symmetries and the corresponding algebra. In Section 3, we discuss the travelling-wave solutions for all the beam forms and further reductions of Euler-Bernoulli form using the scaling symmetries. In Section 4, we study the forced forms of the beam equations. Section 5 is devoted to the singularity analysis of a third-order equation, which is obtained by the reduction of Euler-Bernoulli equation by using the scaling symmetry. Conservation laws for the three beam equations are derived in Section 6. The conclusion and appropriate references are mentioned henceforth.

2 Lie symmetry analysis

For the convenience of the reader, we give a briefly discussion in the theory of Lie point symmetries. In particular, we present the basic definitions and main steps for the determination of Lie point symmetries for a given differential equation. Consider $H^A (t, x, u, u_1) = 0$ to be a set of differential equations and $u_{,i} = \frac{\partial u}{\partial y^i}$ in which $y^i = (t, x)$. 

2
Then under the action of the infinitesimal one-parameter point transformation

\begin{align*}
t' &= t(t, x, u; \varepsilon), \\
x' &= x(t, x, u; \varepsilon), \\
u'^A &= u^A(t, x, u; \varepsilon),
\end{align*}

in which \( \varepsilon \) is an infinitesimal parameter, the set of differential equations \( H^A \) is invariant if and only if,

\[ H^A(t', x', u') = H^A(t, x, u), \]

or equivalently

\[ \lim_{\varepsilon \to 0} \frac{H^A(t', x', u'; \varepsilon) - H^A(t, x, u)}{\varepsilon} = 0. \]

The later expression is the definition of the Lie derivative \( \mathcal{L} \) of \( H^A \) along the direction

\[ \Gamma = \frac{\partial t'}{\partial \varepsilon} \partial_t + \frac{\partial x'}{\partial \varepsilon} \partial_x + \frac{\partial u'}{\partial \varepsilon} \partial_u. \]

Hence, we shall say that the vector field \( \Gamma \) will be a Lie point symmetry for the set of differential equations \( H^A \) if and only if the following condition is true

\[ \mathcal{L}_\Gamma(H^A) = 0. \]

In other words, the operator \( \Gamma \) can be considered to be symmetry provided

\[ \Gamma^{[n]}H^A = 0, \]

whenever \( H^A(t, x, u, u, i) = 0 \) and \( \Gamma^{[n]} \) denotes the \( n \)-th prolongation of the specified operator in its defined space. The set of all such operators can be denoted by \( G \) which can be regarded as the symmetry group for the set of differential equations \( H^A(t, x, u, u, i) = 0 \) [5, 15, 26].

2.1 The Euler-Bernoulli equation.

The Euler-Bernoulli form of the beam equation is [9, 14],

\[ \alpha \beta u_{xxxx} + u_{tt} = 0. \]

The Lie point symmetries are

\begin{align*}
\Gamma_{1a} &= \partial_x, \\
\Gamma_{2a} &= \partial_t, \\
\Gamma_{3a} &= u \partial_u, \\
\Gamma_{4a} &= 2t \partial_t + x \partial_x, \\
\Gamma_{5a} &= a(t, x) \partial_u,
\end{align*}

where \( a(t, x) \) satisfies the Euler-Bernoulli form of beam equation. The Lie Algebra is \((A_{3,3} \oplus A_1) \oplus A_1 \propto A_1\), according to the Morozov-Mubarakzyanov classification scheme [22, 23, 24, 25].

2.2 The Rayleigh equation.

The Rayleigh form of the beam equation is [9, 14],

\[ \alpha \beta u_{xxxx} + u_{tt} - \beta u_{xxtt} = 0. \]

\[ \text{We use the SYM package developed by Prof. Stelios Dimas [10, 11].} \]
The Lie point symmetries are
\[ \Gamma_{1b} = \partial_t, \quad \Gamma_{2b} = \partial_x, \]
\[ \Gamma_{3b} = u \partial_u, \quad \Gamma_{4b} = b(t, x) \partial_u, \]
where \( b(t, x) \) satisfies the Rayleigh form of the beam equation. Consequently, the admitted Lie algebra is \( A_3 \oplus_s \infty A_1 \).

### 2.3 The Timoshenko-Prescott equation.

The Timoshenko and Prescott form of the beam equation is [9, 31],
\[ \alpha \beta u_{xxxx} + \alpha u_{tt} - \beta(1 + \epsilon) u_{xxtt} + \epsilon \beta u_{tttt} = 0. \]
(10)
The Lie point symmetries are
\[ \Gamma_{1c} = \partial_t, \quad \Gamma_{2c} = \partial_x, \]
\[ \Gamma_{3c} = u \partial_u, \quad \Gamma_{4c} = c(t, x) \partial_u, \]
where \( c(t, x) \) satisfies the Timoshenko and Prescott form of the beam equation. Hence, the admitted Lie Algebra is \( A_3 \oplus_s \infty A_1 \).

Therefore, we can say that the Timoshenko-Prescott equation and the Rayleigh equation are algebraic equivalent, but different with the Euler-Bernoulli equation admit a higher-dimensional Lie algebra.

We proceed our analysis by applying the Lie point symmetries to determine similarity solutions for the three equations of our study.

### 3 The travelling-wave solution

The travelling-wave solution for eq (8), with respect to \( \Gamma_{2a} + c \Gamma_{1a} \), where \( c \) denotes the frequency, leads to the fourth order equation,
\[ c^2 \dot{v}''(s) + \alpha \beta v'''(s) = 0, \]
(11)
where
\[ s = x - ct, \]
\[ v(s) = u(x, t). \]
The Lie point symmetries of equation (11) are
\[ \Gamma_{1d} = \partial_s, \]
\[ \Gamma_{2d} = \partial_v, \]
\[ \Gamma_{3d} = s \partial_v, \]
\[ \Gamma_{4d} = \epsilon \partial_v, \]
\[ \Gamma_{5d} = \sin \frac{cs}{\sqrt{\alpha \beta}} \partial_v, \]
\[ \Gamma_{6d} = \cos \frac{cs}{\sqrt{\alpha \beta}} \partial_v. \]
The reduced form has six symmetries and hence linearisable, the solution for the fourth-order equation can be given as,
\[ v(s) = C_0 + C_1 s + C_2 \sin \frac{cs}{\sqrt{\alpha \beta}} + C_3 \cos \frac{cs}{\sqrt{\alpha \beta}}, \]
where \( C_i, i = 0, 1, 2, 3 \) are arbitrary constants. Corresponding, to which the solution for Euler-Bernoulli form of beam can be given as
\[ u(x, t) = C_0 + C_1 (x - ct) + C_2 \sin \frac{c(x - ct)}{\sqrt{\alpha \beta}} + C_3 \cos \frac{c(x - ct)}{\sqrt{\alpha \beta}}. \]
3.1 Further reduction of the Euler-Bernoulli equation.

The reduction with respect to $\Gamma_{3a}$ and $\Gamma_{4a}$, leads to fourth-order odes. For the similarity variables with respect to $2\Gamma_{3a}+\Gamma_{4a}$,

$$s = \frac{t}{x^2},$$
$$u(t, x) = tv(s),$$

the reduced ode is

$$\left(\frac{2}{\alpha \beta} + 120s^2\right)v' + \left(s + 300s^3\right)v'' + 144s^4v'''+16s^5v'''' = 0.$$  \hspace{1cm} (11)

The latter equation is solvable. We continue by considering the similarity variable $u(t, x) = xv(s)$, with respect to $\Gamma_{3a}+\Gamma_{4a}$ for $s$ being same as above leads to the fourth-order ode,

$$24sv' + \left(\frac{1}{\alpha \beta} + 156s^2\right)v'' + 16s^3\left(7v'''+sv''''\right) = 0. $$  \hspace{1cm} (12)

The equation has a total of five Lie point symmetries with $\partial_v$, $v\partial_v$ are the two simpler symmetries, the other three are in terms of Hypergeometric functions, which is complicated enough to be mentioned here.

We apply $\partial_v$ to perform the reduction. The new invariant functions are $s = h$ and $g(h) = v'(s)$, hence, the reduced equation is a third-order ode,

$$g'''(h) = -\frac{7g''(h)}{h} - \left(\frac{39}{4h^2} + \frac{1}{16h^4\alpha \beta}\right)g'(h) - \frac{3g(h)}{2h^3}. $$  \hspace{1cm} (13)

The latter equation admit four Lie point symmetries. The simpler one being $g\partial_g$, the other three are hyperbolic functions of $\sin h, \cos h$ and Hypergeometric function respectively. We consider $g\partial_g$, to do the reduction.

The subsequent second-order equation is,

$$m''(n) = -3m(n) - \left(\frac{7}{n}\right)m'(n) - m(n)^3 - \frac{7m(n)^2}{n} - \left(\frac{39}{4n^2} + \frac{1}{16n^4\alpha \beta}\right)m(n) - \frac{3}{2n^3}, $$ \hspace{1cm} (14)

where $n = h$ and $m(n) = \frac{g''(h)}{g'(h)}$. This is the perturbed form of Painlevé-Ince equation and the singularity analysis of this equation shows that it is integrable. In our subsequent paper we look at the analysis and discuss it elaborately. The reduction of (12) with respect to $v\partial_v$, leads to a third-order equation with zero symmetries,

$$g'''(h) = \left(-4g(h) - \frac{7}{h}\right)g''(h) - 3g'^2 - \left(6g(h)^2 + 21\frac{g(h)}{h} + \frac{39}{4h^2} + \frac{1}{16h^4\alpha \beta}\right)g'(h) - g(h)^4 - \frac{7g(h)^3}{h} - \left(\frac{39}{4h^2} + \frac{1}{16h^4\alpha \beta}\right)g(h)^2 - \frac{3g(h)}{2h^3}. $$ \hspace{1cm} (15)

where $h = s$ and $g(h) = v'(s) s'(s)$. This equation is integrable as ascertained by singularity analysis. The calculations of which are mentioned in a following section.

3.2 The Travelling wave solution for the Rayleigh equation.

The reduction using $\Gamma_{1h} + c\Gamma_{2b}$ leads to the fourth-order equation which is maximally symmetric, where $c$ is the frequency. The definition of similarity variables $s$ and $v(s)$ is similar to that of the previous case.

$$(1 - \beta c^2) v'''(s) + c^2v''(s) = 0, $$ \hspace{1cm} (16)

which is in the form of equation (11).
3.3 The travelling-wave solution for the Timoshenko-Prescott equation.

In a similar way, the application of the generic symmetry vector, \( \Gamma_{1c} + c\Gamma_{2c} \), in (10) provide the fourth-order ode,

\[
(\alpha^2\beta - \beta c^2 a - \alpha \beta c^2 \varepsilon + c^4 \varepsilon \beta) v'''(s) + ac^2 v''(s) = 0,
\]

which is again in the form of (11). Consequently, we conclude that the three different beam equations provide the same travel-wave solutions.

We continue our analysis by assuming the existence of a source term \( f(u) \) in the beam equations.

4 Symmetry analysis with a source term

In this section, we study the impact of the forcing-source term \( f(u) \) in the rhs of the Euler-Bernoulli, Rayleigh and Timoshenko-Prescott beam equations.

4.1 Euler-Bernoulli.

The Lie symmetry analysis for the Euler-Bernoulli equation (8) with forced term \( f(u) \), leads to the following possible cases for the forcing term

\[
\begin{align*}
  f_1(u) & = au + b, \\
  f_2(u) & = (au + b)^n, \\
  f_3(u) & = e^{au + b}, \\
  f_4(u) & = \text{arbitrary}.
\end{align*}
\]

For \( f_1(u) \), the admitted Lie point symmetries for the Euler-Bernoulli equation are,

\[
\begin{align*}
  \Gamma_{f_1}^1 & = \partial_t, \\
  \Gamma_{f_1}^2 & = \partial_x, \\
  \Gamma_{f_1}^3 & = u\partial_u, \\
  \Gamma_{f_1}^4 & = b(t, x)\partial_u,
\end{align*}
\]

where they form the \( 3A_1 \) Lie Algebra and \( b(t, x) \) is a solution of the original equation.

For the source \( f_2(u) \), the admitted Lie point symmetries are,

\[
\begin{align*}
  \Gamma_{f_2}^1 & = \partial_t, \\
  \Gamma_{f_2}^2 & = \partial_x, \\
  \Gamma_{f_2}^3 & = 2(n - 1)t\partial_t + (n - 1)x\partial_x - 4 u + \frac{b}{a} \partial_u,
\end{align*}
\]

which they form the \( 2A_1 \oplus A_1 \) Lie Algebra.

For \( f_3(u) \) the admitted Lie point symmetries are,

\[
\begin{align*}
  \Gamma_{f_3}^1 & = \partial_t, \\
  \Gamma_{f_3}^2 & = \partial_x, \\
  \Gamma_{f_3}^3 & = 2t\partial_t + x\partial_x - 4 a \partial_u,
\end{align*}
\]

where the corresponding Lie Algebra is the \( 2A_1 \oplus A_1 \).

Finally for arbitrary functional form of \( f(u) \) the admitted Lie point symmetries are the only two symmetry vectors,

\[
\begin{align*}
  \Gamma_{f_4}^1 & = \partial_t, \\
  \Gamma_{f_4}^2 & = \partial_x,
\end{align*}
\]

which form the \( 2A_1 \) Lie Algebra and provide the travelling-wave solution.

4.2 Rayleigh and Timoshenko-Prescott equations.

For the other two beam equations, namely the Rayleigh and Timoshenko-Prescott equations with a source term, we find that for a linear function \( f = f_1(u) \), the two equations admit the same Lie point symmetries with the force-free case, while for arbitrary function \( f(u) = f_4(u) \), admit only two Lie point symmetries, the vector fields \( \Gamma_{f_4}^1 \), \( \Gamma_{f_4}^2 \) which provide with travelling-wave solutions.
4.3 Symmetry classification of ODE.

As we show above the reduction with the Lie point symmetries, $\Gamma^{f_4}_1 + c\Gamma^{f_4}_2$, for the three beam equations of our consideration provide the same fourth-order ODE, which now with a source term it takes the following form,

$$v''' + c^2 v'' = f(v), \quad (22)$$

We perform the symmetry classification of the latter differential equation and we find that for arbitrary function $f(v)$, the latter equation admits only the autonomous symmetry vector $\partial_v$. However, for a constant source $f(v) = a_0$, the Lie point symmetries are,

$$\partial_s, \partial_v, s \partial_v, (2c^2 v - a_0 s^2) \partial_v, \cos(cs) \partial_v, \sin(cs) \partial_v,$$

where the generic solution of equation (22) is,

$$v(s) = v_1 \sin(cs) + v_2 \cos(cs) + v_3 s + v_4 + \frac{a_0}{2c^2}s^2. \quad (23)$$

On the other hand, for $f(v) = a_1 v + a_0$, equation (22) admits the six Lie point symmetries,

$$\partial_s, (a_1 v + a_0) \partial_v, \exp\left(\pm i\sqrt{2c^2 + 2\sqrt{c^4 + 4a_1}} s\right) \partial_v, \exp\left(\pm i\sqrt{2c^2 - 2\sqrt{c^4 + 4a_1}} s\right) \partial_v,$$

where the generic solution of (22) is,

$$v(s) = v_1 \exp\left(i\sqrt{2c^2 + 2\sqrt{c^4 + 4a_1}} s\right) + v_2 \exp\left(-i\sqrt{2c^2 - 2\sqrt{c^4 + 4a_1}} s\right) + v_3 \exp\left(+i\sqrt{2c^2 - 2\sqrt{c^4 + 4a_1}} s\right) + v_4 \exp\left(-i\sqrt{2c^2 - 2\sqrt{c^4 + 4a_1}} s\right). \quad (24)$$

4.4 Scaling solutions for the forced Euler-Bernoulli equation.

We continue by presenting the reduction with the scaling symmetries for the Euler-Bernoulli equation for the power-law and the exponential sources $f_2(u)$ and $f_3(u)$. For simplicity and without loss of generality we select $b = 0$.

For the power-law source $f_2(u) = au^n$, the application of the Lie point symmetry $\Gamma^{f_2}_3$ provides the reduced fourth-order ode,

$$4\alpha \beta v''' + s^2 v'' + \frac{3n + 5}{n - 1}sv' + \frac{8(1 + n)v}{(n - 1)^2} - 4av^n = 0, \quad (25)$$

in which $s = \frac{x}{\sqrt{t}}$ and $u(t, x) = v(s) t^{-\frac{n-1}{2}}$.

On the other hand, for the exponential source $f_3(u) = e^{au}$, the reduced equation given by the scaling symmetry is,

$$4\alpha \beta v''' + s^2 v'' + 3av' + 4ae^{av} + 8 = 0, \quad (26)$$

where now $s = \frac{x}{\sqrt{t}}$ and $u(t, x) = -\frac{2}{a} \ln(t) + v(s)$.

5 Singularity analysis

The third-order ode that we apply the singularity analysis is (15) or

$$24u xy(x) + y(x)^2 + 156u x^2 y(x)^2 + 112ux^3 y(x)^3 + 16ux^4 y(x)^4 + y'(x) + 156ux^2 y'(x) + 336ux^3 y'(x) + 96ux^4 y'(x) + 48ux^5 y'(x) + 112ux^3 y''(x) + 64ux^4 y''(x) + 16ux^4 y'''(x) = 0, \quad (27)$$
where \( g(h) = y(x) \), \( h = x \) and \( \alpha \beta = v \). We apply the ARS algorithm \([1, 2, 3]\) and we make the usual substitution to obtain the leading-order behaviour \([27]\),

\[
y \to a(x - x_0)^p,
\]

which provides

\[
32a\nu px^4(x - x_0)^{-3+p} - 48a\nu^2x^4(x - x_0)^{-3+p} + 16a\nu^3x^4(x - x_0)^{-3+p} - 112a\nu px^3(x - x_0)^{-2+p} \\
+ 112a\nu^2x^3(x - x_0)^{-2+p} + ap(x - x_0)^{-1+p} + 156a\nu px^2(x - x_0)^{-1+p} + 24a\nu x(x - x_0)^p \\
+ a^2(x - x_0)^2p + 156a^2\nu x^2(x - x_0)^2p + 112a^3\nu x^3(x - x_0)^3p + 16a^4\nu x^4(x - x_0)^4p \\
- 64a^2\nu px^4(x - x_0)^{-2+2p} + 112a^2\nu px^4(x - x_0)^{-2+2p} + 336a^2\nu px^3(x - x_0)^{-1+2p} \\
+ 96a^3\nu px^4(x - x_0)^{-1+3p} = 0.
\]

From the latter it is evident that \( p \to -1 \). Hence,

\[
\frac{-96a\nu x^4}{(x - x_0)^4} + \frac{176a^2\nu x^4}{(x - x_0)^4} - \frac{96a^3\nu x^4}{(x - x_0)^4} + \frac{16a^4\nu x^4}{(x - x_0)^4} + \frac{224a\nu x^3}{(x - x_0)^3} \\
- \frac{336a^2\nu x^3}{(x - x_0)^3} + \frac{112a^3\nu x^3}{(x - x_0)^3} - \frac{a}{(x - x_0)^2} \\
+ \frac{a^2}{(x - x_0)^2} - \frac{156a\nu x^2}{(x - x_0)^2} + \frac{156a^2\nu x^2}{(x - x_0)^2} + \frac{24a\nu x}{x - x_0}.
\]

We extract the obvious dominant terms,

\[
\frac{-96a\nu x^4}{(x - x_0)^4} + \frac{176a^2\nu x^4}{(x - x_0)^4} - \frac{96a^3\nu x^4}{(x - x_0)^4} + \frac{16a^4\nu x^4}{(x - x_0)^4},
\]

and solve for \( a \),

\[
(-3 + a)(-2 + a)(-1 + a)a = 0,
\]

(32)

to obtain,

\[
a \to 0, a \to 1, a \to 2, a \to 3.
\]

(33)

In order to find the resonances, we substitute,

\[
y \to a(x - x_0)^{-1} + m(x - x_0)^{-1+s},
\]

(34)

and we linearize around \( m \). Then the usual \( x \to z + x_0 \), simplify the calculations and provide the dominant terms factor as,

\[
16\nu(-3 + 2a + s)(2 - 6a + 2a^2 - 3s + 2as + s^2)x_0\frac{4-4+s}{x_0^4},
\]

(35)

and for the three values of \( a \), we obtain the three sets of resonances, for each value of the coefficient term \( a \):

\[
a = 1 : s \to -1, s \to 1, s \to 2,
\]

\[
a = 2 : s \to -2, s \to -1, s \to 1,
\]

\[
a = 3 : s \to -3, s \to -2, s \to -1.
\]

For \( a = 1 \), the solution is expressed in terms of a Right Painlevé Series, for \( a = 3 \), in terms of a Left Painlevé Series and for \( a = 2 \), in terms of a Mixed Painlevé Series.

We commence the consistency test. For the Right Painlevé Series, we write

\[
y \to (x - x_0)^{-1} + F_0 + F_1(x - x_0) + F_2(x - x_0)^2 + F_3(x - x_0)^3 + ...
\]

(36)
where $F_0$ and $F_1$ are the second and third constants of integration. The output is enormous and hence omitted.

The substitution $x \rightarrow z + x_0$, just makes it easier to collect like powers. The terms in $z^{-1}$ are,

$$
\frac{2F_0}{z} + \frac{24Fx_0}{z} + \frac{3F_0^2x_0}{z}^2 + \frac{336F_0^2x_0^3}{z} + \frac{336F_1x_0^3}{z} + \frac{64F_0^2x_0^4}{z} + \frac{192F_0F_1x_0^4}{z} + \frac{128F_2x_0^4}{z} + \ldots = 0. \tag{37}
$$

This is solved to give,

$$
64x_0^4F_2 \rightarrow -F_0 - 12x_0 - 156F_0x_0^2 + 168F_0^2x_0^3 + 168F_1x_0^3 - 32a_0^3x_0^4 - 96F_0F_1x_0^4.
\tag{38}
$$

The expression for $F_2$ is substituted into the major output,

$$
-7F_0^3 + 3F_1 - 240\nu - \frac{22F_0}{x_0} - 2880F_0\nu x_0 - 3780F_0^2\nu x_0^3 - 2220F_1\nu x_0^2 + 1680F_0^2\nu x_0^3 - 1680F_0F_1\nu x_0^3 - 240F_0^4\nu x_0^4 + 480F_0^2F_1\nu x_0^4 + 480F_0\nu x_0^5 = 0,
\tag{39}
$$

and the coefficient of the constant term is solved to give $F_3$ as,

$$
480\nu x_0^5F_3 = 22F_0 + 7F_0^2x_0 - 3F_1x_0 + 240x_0^2 + 2880F_0\nu x_0^3 + 3780F_0^2\nu x_0^3 + 2220F_1\nu x_0^2 + 1680F_0^2\nu x_0^3 + 1680F_0F_1\nu x_0^3 + 240F_0^4\nu x_0^4 + 480F_0^2F_1\nu x_0^4 - 240F_1^2\nu x_0^5.
\tag{40}
$$

Thus there is not a problem with the determination of the coefficients of the terms in the Right Painlevé Series. As the terms, not included in those which are dominant are less dominant, there cannot be a Left Painlevé Series. The possibility of the existence of a Mixed Painlevé Series is moot due to the practical difficulty of calculating coefficients. Consequently, equation (15) is integrable according to the Painlevé test.

## 6 Conservation laws

The Ibragimov’s theory of nonlinear self-adjointness details to construct conservation laws for a scalar pde\cite{18,19,80}. Our first step is to verify the self-adjointness condition on the various form of beam and later on compute the conservation laws. The preliminaries can be easily accessed from\cite{18}.

The main motivation behind using the Ibragimov’s approach is to obtain the conservation laws to deduce certain special solutions for the Beam equations following the methodology specified by Cimpoiasu \cite{21} where the author have used the nonlinear self-adjointness method to compute solutions for the Rossby waves. The Noether’s theorem can be easily applied to obtain the conserved terms but it is our intuition that the non-local conserved terms as obtained using the Ibragimov’s method can contribute in obtaining new solutions in a different subspace of the complex plane. The main objective is to deduce new solutions using the point symmetries, singularities and conservation laws. For instance, the Euler-Bernoulli equation does imply the existence of series type solutions through the method of Singularity analysis as mentioned in Section 5 for equation (15).

Let the scalar PDE admit the following generators of the infinitesimal transformation,

$$
V = \xi^i(x, u, u_i, \ldots) \frac{\partial}{\partial x^i} + \eta(x, u, u_i, \ldots) \frac{\partial}{\partial u}.
\tag{41}
$$

Then the scalar PDE and its adjoint equation, as defined above, admits the conservation law

$$
C^i = \xi^iL + W \left( \frac{\partial L}{\partial u_i} - D_j \left( \frac{\partial L}{\partial u_{ij}} \right) + D_{jk} \left( \frac{\partial L}{\partial u_{ijk}} \right) - \ldots \right) + D_j(W) \left( \frac{\partial L}{\partial u_{ij}} - D_k \left( \frac{\partial L}{\partial u_{ijk}} \right) + \ldots \right) + D_jD_k(W) \left( \frac{\partial L}{\partial u_{ijk}} - \ldots \right),
$$

where $\xi^i$ and $\eta$ are the infinitesimal generators of the transformation.
where \( W = \eta - \xi u_i \) and \( L \) denotes the Lagrangian of the corresponding form of the beam equation. For the Euler-Bernoulli, Rayleigh and Timoshenko-Prescott forms the Lagrangians are as follows

\[
L = q(t, x)(u_{tt} + \alpha \beta u_{xxxx}),
\]

\[
L = q(t, x)(\alpha \beta u_{xxxx} + u_{tt} - \beta u_{xxxx}),
\]

\[
L = q(t, x)(\alpha \beta u_{xxxx} + u_{tt} - \beta (1 + \epsilon) u_{xxxx} + \frac{\epsilon \beta u_{ttt}}{\alpha}),
\]

where \( q(t, x) \) is the new dependent variable. To verify the non-linear self adjointness the substitution of \( q(t, x) = \phi(t, x, u) \), to the adjoint equation of (45), (46) and (47) must satisfy for all solutions \( u \) of those equations. The possible values of \( \phi(t, x, u) \) is a constant term, let say, \( A_0 \) and \( A_1 u(t, x) + A_2 \), where \( A_1 \) and \( A_2 \) are arbitrary constants. A complete description of this method can be obtained from [18].

### 6.1 Conservation laws for the various form of beam.

With respect to, each of the symmetry in (33), we compute the nonzero conservation laws. For \( \Gamma_{1a} \) the conservation components are

\[
c^t = u_x \phi_t - u_{xt} \phi(t, x, u),
\]

\[
c^x = \phi(t, x, u)(u_{tt} + \alpha \beta u_{xxxx}) + \alpha \beta u_x \phi_{xxxx} - \alpha \beta u_{xx} \phi_{xx} + \alpha \beta \phi_x u_{xx} - u_{xxxx} \phi(t, x, u).
\]

For \( \Gamma_{2a} \),

\[
c^t = \phi(t, x, u)(u_{tt} + \alpha \beta u_{xxxx}) + u_{tt} \phi - u_{xt} \phi(t, x, u),
\]

\[
c^x = \alpha \beta(\phi_{xx} - u_{xt} \phi_x - u_{xxxx} \phi(t, x, u)).
\]

For \( \Gamma_{3a} \),

\[
c^t = -u \phi_t + u_t \phi(t, x, u),
\]

\[
c^x = \alpha \beta(u_x \phi_{xx} - u \phi_{xx} + u_{xx} \phi_x + u_{xxxx}).
\]

For \( \Gamma_{4a} \),

\[
c^t = 2(t(\phi(t, x, u)(u_{tt} + \alpha \beta u_{xxxx})) + \phi_t(2tu_t + xu_x) - \phi(t, x, u)(2tu_{tt} + 2u_t + xu_x),
\]

\[
c^x = x(\phi(t, x, u)(u_{tt} + \alpha \beta u_{xxxx})) + \alpha \beta \phi_{xx}(2tu_t + xu_x) - \alpha \beta \phi_{xx}(2tu_{xx} + xu_{xx} + u_x)
\]

\[
+ \alpha \beta \phi_x(2tu_{xx} + xu_{xx} + 2u_x) - \alpha \beta \phi(t, x, u)(2tu_{xxxx} + xu_{xxxx} + 3u_{xxx}).
\]

For \( \Gamma_{5a} \),

\[
c^t = -a(t, x) \phi_t + a_t \phi(t, x, u),
\]

\[
c^x = -\alpha \beta a(t, x) \phi_{xxx} + \alpha \beta a_x \phi_{xx} - \alpha \beta a_{xx} \phi_x + \phi(t, x, u)a_{xxx}.
\]

Next we compute the conservation laws of equation (39), with respect to its symmetries. \( \Gamma_{1b} \) leads to the following conserved components,

\[
c^t = \phi(t, x, u)(\alpha \beta u_{xxxx} + u_{tt} - \beta u_{xxxx}) + u_t \phi_t - \phi(t, x, u)u_{tt},
\]

\[
c^x = \alpha \beta(u_t \phi_{xxx} - u_{xx} \phi_x + u_{xx} \phi_x - u_{xxxx} \phi(t, x, u)).
\]
For $\Gamma_{2b}$,
\[
\begin{align*}
c^t &= u_x \phi_t - u_xt \phi(t, x, u), \\
c^x &= \phi(t, x, u)(\alpha \beta u_{xxxx} + u_{tt} - \beta u_{xtt}) + \alpha \beta(u_x \phi_{xx} - u_{xx} \phi_x + u_{xxx} \phi_x - \phi(t, x, u)u_{xxxx}).
\end{align*}
\] (48)

For $\Gamma_{3b}$,
\[
\begin{align*}
c^t &= u_t \phi(t, x, u) - u \phi_t, \\
c^x &= \alpha \beta(u_x \phi_{xx} - u_{xx} \phi_x + u_{xxx} \phi(t, x, u)).
\end{align*}
\] (49)

For $\Gamma_{4b}$,
\[
\begin{align*}
c^t &= b_t \phi(t, x, u) - b(t, x) \phi_t, \\
c^x &= \alpha \beta(b_x \phi_{xx} - b(t, x) \phi_{xxx} - b_{xx} \phi_x + b_{xxx} \phi(t, x, u)).
\end{align*}
\] (50)

For the Timoshenko-Prescott form of the beam [111], the conserved components are as follows:

For $\Gamma_{1c}$,
\[
\begin{align*}
c^t &= \phi(t, x, u) \left( \alpha \beta u_{xxxx} + u_{tt} - \beta(1 + \epsilon)u_{xtt} + \frac{\epsilon \beta u_{tttt}}{\alpha} \right) + u_t \left( \phi_t + \frac{\epsilon \beta \phi_{ttt}}{\alpha} \right) - u_{tt} \left( \phi(t, x, u) + \frac{\epsilon \beta \phi_{tt}}{\alpha} \right) \\
&\quad + u_{ttt} \frac{\epsilon \beta \phi_t}{\alpha} - u_{tttt} \frac{\epsilon \beta \phi(t, x, u)}{\alpha}, \\
c^x &= \alpha \beta(u_x \phi_{xx} - u_{xt} \phi_x + u_{xxt} \phi(t, x, u)).
\end{align*}
\] (51)

For $\Gamma_{2c}$,
\[
\begin{align*}
c^t &= u_x \left( \phi_t + \frac{\epsilon \beta \phi_{ttt}}{\alpha} \right) - u_{xt} \left( \phi(t, x, u) + \frac{\phi_{tt} \epsilon \beta}{\alpha} \right) + u_{xtt} \frac{\phi_t \epsilon \beta}{\alpha} - u_{xttt} \frac{\epsilon \beta}{\alpha}, \\
c^x &= \phi(t, x, u) \left( \alpha \beta u_{xxxx} + u_{tt} - \beta(1 + \epsilon)u_{xtt} + \frac{\epsilon \beta u_{tttt}}{\alpha} \right) \\
&\quad + \alpha \beta(u_x \phi_{xx} - u_{xx} \phi_x + u_{xxx} \phi - \phi(t, x, u)u_{xxxx}).
\end{align*}
\] (52)

For $\Gamma_{3c}$,
\[
\begin{align*}
c^t &= -u \left( \phi_t + \frac{\epsilon \beta \phi_{ttt}}{\alpha} \right) + u_t \left( \phi(t, x, u) + \frac{\epsilon \beta \phi_{tt}}{\alpha} \right) - u_{tt} \frac{\epsilon \beta \phi_t}{\alpha} + u_{ttt} \frac{\epsilon \beta \phi(t, x, u)}{\alpha}, \\
c^x &= \alpha \beta(u_x \phi_{xx} - u_{xx} \phi_x - u_{xxx} \phi + u_{xxxx} \phi(t, x, u)).
\end{align*}
\] (53)

For $\Gamma_{4c}$,
\[
\begin{align*}
c^t &= -c(t, x) \left( \phi_t + \frac{\epsilon \beta \phi_{ttt}}{\alpha} \right) + c_t \left( \phi(t, x, u) + \frac{\epsilon \beta \phi_{tt}}{\alpha} \right) - c_{tt} \frac{\epsilon \beta \phi_t}{\alpha} + c_{ttt} \frac{\epsilon \beta \phi(t, x, u)}{\alpha}, \\
c^x &= \alpha \beta(c_x \phi_{xx} - c(t, x) \phi_{xxx} - c_{xx} \phi_x + c_{xxx} \phi(t, x, u)).
\end{align*}
\] (54)
7 Conclusion

In this work, we focused on the algebraic properties for three different forms of the beam equations with or without source. For the source free equations we found that the Euler-Bernoulli equation is invariant under the Lie algebra \((A_3 \oplus A_1) \oplus_s \infty A_1\), while, the Rayleigh and Timoshenko-Prescott equations are invariant under the Lie algebra \(A_3 \oplus \infty A_1\).

In the case of a isotropic source \(f(u)\) we found that the Euler-Bernoulli, Rayleigh and Timoshenko-Prescott equations are invariant under the Lie algebra \(A_3 \oplus s \infty A_1\) for Linear \(f(u) = au + b\), \(2A_1 \oplus_A A_1\) for exponential or power-law functional form. For the other two beam equations there are not specific functional forms of \(f(u)\), where the equations admit different algebras. Therefore, for the source-free equations we derived the conservation laws by applying the Ibragimov’s method.

We applied the Lie point symmetries to reduce the pdes and we proved that the three beam equations provide exactly the same travelling-wave solutions. The most important result of our paper is the reduction of Euler-Bernoulli equation to a second-order equation, of the form of perturbed Painlevé-Ince equation and to a third-order equation, which was studied by Chazy, Bureau and Cosgrove. One of our subsequent paper will be on the singularity analysis of the perturbed Painlevé-Ince equation. Moreover, our future work also includes deriving further solutions of the different forms of beam using conservation laws.
