Abstract. Radiative corrections to the single top $s$ and $t$ channel production processes are revisited. Complete one-loop electroweak corrections are calculated within the SANC system. New is a study of the regularisation of the top-legs associated infrared divergences with aid of the complex mass of the top quark. A comparison of these electroweak corrections with those computed by the conventional method is presented both for top production and decays. Standard FORM and FORTRAN SANC modules are created. These modules are compiled into a package sanc\_cc\_v1.40, which may be downloaded from SANC project homepages. Numerous numerical results are presented at the partonic level with the aim to demonstrate the correct working of modules. These modules are intended to be used in Monte Carlo generators for single top production at the LHC. Where possible, we compare our results with those existing in the literature; in particular, a comprehensive comparison with results of the CompHEP system is given.

Key words. electroweak radiative corrections – helicity amplitudes

PACS. 1 2.15.-y Electroweak interactions; 12.15.Lk Electroweak radiative corrections
1 Introduction

In continuation of work on electroweak one-loop corrections to processes involving the top quark \[1,2\], we present here a calculation of EW one-loop corrections to single top quark production and top quark decay. To incorporate these processes in the SANC framework \[3\] is a natural extension of the previous work.

The interest in the study of single top production has been stated many times (see e.g. \[4\] and references therein), suffice it to say that this is the only way of measuring the CKM matrix element \(|V_{tb}|\) directly and thereby providing a sensitive test of the 3-generation scheme of the Standard Model. Indeed, a significant deviation of \(|V_{tb}|\) from the value demanded by unitarity of the CKM matrix would be an indication of the presence of a fourth generation of fundamental fermions.

Precision calculations of single top quark production have been done for a number of years (see e.g. \[5\] and references therein) but remain of continued interest. This is motivated on the one hand by the observation of such events at the Tevatron D0 \[6,7\] and CDF \[8,9\] and, on the other hand, by the need to prepare software to analyse single top quark events at the LHC, running at 7 TeV.

Most of the theoretical work in single top production has been concerned with higher order QCD corrections, leading to the development of Monte Carlo generators, such as MC@NLO \[10\] or SingleTop \[11\], incorporated in the standard LHC tools.

There are three channels of single top quark production: \(t\) channel, \(s\) channel and associated production. The \(t\) channel process, \(bq \rightarrow tq',\) where \(q\) and \(q'\) are light quarks, is the channel known to have the largest cross section \[12-15\]. Calculations for the LHC at 14 TeV have led to the prediction of this cross section being more than an order of magnitude greater than that of the \(s\) channel process \(qq' \rightarrow tb\) and about four times greater than the cross section of associated production \(qq \rightarrow tW\) (see e.g. \[16\]), and it has been stated that the electroweak corrections are of comparable magnitude to the QCD corrections \[12\].

In this paper we calculate the electroweak corrections to the \(s\) and \(t\) channels of single top quark production and revisit the top quark decay \[2\]. The important new feature of the present work is the inclusion in the calculations of the width \(\Gamma_t\) of the top quark. This is a nontrivial step, and we will show that the results are sensitive to \(\Gamma_t\).

The paper is organized as follows.

In section 2 we present the covariant amplitudes for the processes under consideration, working within the framework of the multichannel approach (see Ref \[17\]).
radiation. Numerical results are presented in section 4 and the Conclusions and Outlook in section 5.

2 Covariant Amplitude

In this section we proceed in the spirit of “multi-channel approach”, see Ref. [17]. First, we consider annihilation into vacuum with all particles incoming.

2.1 All particles incoming

It is convenient to consider two vacuum diagrams:

\[ \begin{align*}
\bar{b} & \quad d \\
p_1 & \quad p_4 \\
p_2 & \quad p_3 \\
t & \quad \bar{u}
\end{align*} \]

Fig. 1. The $\bar{b}ud \rightarrow 0$ processes

and

\[ \begin{align*}
\bar{t} & \quad u \\
p_1 & \quad p_4 \\
p_2 & \quad p_3 \\
b & \quad \bar{d}
\end{align*} \]

Fig. 2. The $\bar{t}ud \rightarrow 0$ processes

Here black ovals symbolically denote all one-loop insertions to the corresponding tree diagrams.

Covariant Amplitudes (CA) of Figs. 1 and 2 are characterized by four different structures and scalar Form Factors (FF) if the mass of the light quarks is neglected and $b$ quark mass is not neglected. Omitting Dirac spinors, one may write a common expression for this CA of the process in terms of scalar form factors, $F_{LL}(s, t)$, see [3]:

\[ A = i e^2 \frac{d_w(s)}{4} \left[ \gamma_\mu (1 + \gamma_5) \otimes \gamma_\mu (1 + \gamma_5) F_{LL}(s, t) + \gamma_\mu (1 - \gamma_5) \otimes \gamma_\mu (1 + \gamma_5) F_{NL}(s, t) 
+ (1 + \gamma_5) \otimes \gamma_\mu (1 + \gamma_5) (-i D_\mu) F_{LD}(s, t) 
+ (1 - \gamma_5) \otimes \gamma_\mu (1 + \gamma_5) (-i D_\mu) F_{RD}(s, t) \right], \]

with

\[ D_\mu = (p_1 - p_2)_\mu, \]

and 4-momentum conservation reads

\[ p_1 + p_2 + p_3 + p_4 = 0, \]

the invariants are defined by

\[ s = -(p_1 + p_2)^2, \quad t = -(p_2 + p_3)^2, \]

and

\[ d_w(s) = \frac{V^2}{2s_w} \frac{1}{s - M_w^2 + i M_w T_w}. \]

Here $V = V_{tb} V_{ud}$ is the relevant product of CKM matrix elements and the symbol $\otimes$ means, considering the factor of $F_{LL}$ in diagram Fig. [1]
and appropriate changes in the other cases. The scalar form factors $F$ are labeled according to their structures, see [3].

### 2.2 Conversion to top decay

The CA for the decay $t(p_2) \rightarrow b(p_1) + u(p_3) + d(p_4)$ is derived from Fig. [1] by the following 4-momentum replacement:

- $p_1 \rightarrow -p_1$, $p_3 \rightarrow -p_3$,
- $p_2 \rightarrow p_2$, $p_4 \rightarrow -p_4$.

For the decay $\bar{t}(p_1) \rightarrow \bar{b}(p_2) + d(p_3) + \bar{u}(p_4)$ it is more transparent to make the replacement from Fig. [2]

- $p_1 \rightarrow p_1$, $p_3 \rightarrow -p_3$,
- $p_2 \rightarrow -p_2$, $p_4 \rightarrow -p_4$.

As a result one has two decay diagrams, schematically representing one-loop EW corrections:

![Fig. 3. The $t \rightarrow bud$ processes](image)

![Fig. 4. The $\bar{t} \rightarrow \bar{b}ud$ processes](image)

### 2.3 Conversion to $s$ channel

The CA for the $s$ channel single-top production processes $\bar{u}(p_1) + d(p_2) \rightarrow b(p_3) + \bar{t}(p_4)$ is obtained from Fig. [1] by the following 4-momentum replacement:

- $p_1 \rightarrow -p_3$, $p_3 \rightarrow p_1$,
- $p_2 \rightarrow -p_4$, $p_4 \rightarrow -p_2$.

leading to the diagram

![Fig. 5. The $\bar{u}d \rightarrow \bar{t}b$ process](image)

For the processes $\bar{d}(p_1) + u(p_2) \rightarrow t(p_3) + \bar{b}(p_4)$ from Fig. [2] the conversion

- $p_1 \rightarrow -p_3$, $p_3 \rightarrow p_1$,
- $p_2 \rightarrow -p_4$, $p_4 \rightarrow p_2$,

leads to the diagram of Fig. [6]

For the corresponding HA one can get rather compact expressions.

- Helicity amplitude for $\bar{u}d \rightarrow \bar{t}b$

$$\mathcal{H}_{+-} = k_0 \sin \vartheta \left( m_c k_1 + m_b k_2 \right) F_{LL}$$
Helicity amplitude for $\bar{\chi}^+ + \bar{\chi}^+ = P^- + P^+$,

\[ P^\pm = \sqrt{s - (m_t + m_b)^2}, \]

\[ c_\pm = 1 \pm \cos \vartheta \]  

and $\vartheta$ is always the angle $\angle(p_1, p_3)$.

### 2.4 Conversion to $t$ channel processes

In the CAs for the $t$ channel single-top production processes $\bar{b}(p_1) + \bar{u}(p_2) \rightarrow \bar{d}(p_3) + \bar{t}(p_4)$ and $\bar{b}(p_1) + d(p_2) \rightarrow u(p_3) + \bar{t}(p_4)$ it is convenient to make the replacement “in pairs”. From Fig. 4 one may perform two 4-momentum replacements:

\begin{align*}
& p_1 \rightarrow p_1, & p_1 \rightarrow \bar{p}_1, \\
& p_2 \rightarrow -p_4, & p_2 \rightarrow -p_4, \\
& p_3 \rightarrow p_2, & p_3 \rightarrow -p_3, \\
& p_4 \rightarrow -p_3, & p_4 \rightarrow p_2,
\end{align*}

which give rise to two different physical $t$ channel processes, described by two symbolic diagrams:

**Fig. 6.** The $\bar{d}u \rightarrow t\bar{b}$ processes

**Fig. 7.** The $\bar{b}u \rightarrow \bar{t}\bar{d}$ and $\bar{b}d \rightarrow \bar{t}u$ processes
from Fig. 2

\[ p_1 \rightarrow -p_4, \quad p_1 \rightarrow -p_4, \]
\[ p_2 \rightarrow p_1, \quad p_2 \rightarrow p_1, \]
\[ p_3 \rightarrow -p_3, \quad p_3 \rightarrow p_2, \]
\[ p_4 \rightarrow p_2, \quad p_4 \rightarrow -p_3, \]
gives the corresponding pair of symbolic diagrams for the two remaining \( t \) channel processes:

\[ \text{Fig. 8. The } b^u \rightarrow t\bar{d} \text{ and } b\bar{d} \rightarrow t\bar{u} \text{ processes} \]

The HAs are all different for the four types of processes. They are listed below in another sequence than they were presented diagrammatically above. First, we give the more complicated HAs for 4-particle and 4-antiparticle processes:

• Helicity amplitudes for \( ub \rightarrow td \)

\[
\mathcal{H}_{---+} = k_0 \left\{ N^+ \sqrt{s} c_+ \left[ 2m_{t+b} F_{LL} \right. \right.
\]
\[
+ \frac{m_t}{s} \left( c_- s_b F_{RL} - k_2 F_{LD} \right) \left. \right] - k_1 F_{LD} \left. \right] - k_1 F_{RL} \right\} \cdot k_s \left( \frac{k_2}{s} F_{RL} + c_+ s_b (F_{LD} - F_{RD}) \right),
\]
\[
\mathcal{H}_{---+} = k_0 \sin \vartheta \left\{ N^+ c_+ s_b \left[ F_{RL} \right. \right.
\]
\[
+ m_t (F_{LD} - F_{RD}) \left. \right]\left. \right] - k_1 F_{LD} \left. \right] \right\} \cdot \frac{m_t}{s} \left( \frac{k_2}{s} F_{RL} + c_+ s_b (F_{LD} - F_{RD}) \right). \]

The other notation common to Eqs. (9) and (13) is

[\[ s_{tb} = s + m_t m_b, \quad m_{t+b} = m_t + m_b, \]
\[ s_t = s - m_t^2, \quad s_b = s - m_b^2, \]
\[ c_\pm = 1 \pm \cos \vartheta, \]
\[ N = \sqrt{\frac{2s}{s_{tb}^2 c_- + s m_t^2 c_+}}, \]
\[ N_{(2,3)} = N_{(3,2)} = \frac{\sqrt{2s s_b}}{2}, \]
\[ N^+ = \frac{m_{t+b}}{\sqrt{2s}}, \quad N^- = \frac{s_{tb}}{\sqrt{2s}} \]

• Helicity amplitudes for \( \bar{b}\bar{u} \rightarrow \bar{t}\bar{d} \)

\[
\mathcal{H}_{---+} = k_0 \left\{ N^+ \sqrt{s} c_+ \left[ \frac{k_2}{s} F_{RL} \right. \right. \]
\[
+ N^- \sqrt{s} \left\{ k_2 F_{RL} \right. \right. \]
\[
- k_1 F_{LD} \left. \right] - m_t k_2 F_{RD} \right\} \cdot \frac{m_t}{s} \left( \frac{k_2}{s} F_{RL} + c_+ s_b (F_{LD} - F_{RD}) \right). \]
\[
-(2m_{t+b}m_t + c_- s_t)F_{LD} - \frac{m_b k_2}{s} F_{RD}
\]
\[
-N^+ c_- \left[2s_{tb} F_{LL}
- m_b \left(\frac{k_2}{s} F_{RL} + c_+ s_t (F_{LD} - F_{RD})\right)\right],
\]
\[
\mathcal{H}_{-+-} = k_0 \sin \vartheta \left\{ N^+ \left[2s_{tb} F_{LL}
- m_b \left(\frac{k_2}{s} F_{RL} + c_+ s_t (F_{LD} - F_{RD})\right)\right]\right\},
\]
\[
\mathcal{H}_{+-+} = k_0 \sin \vartheta \left\{ -N^+ c_+ s_t \left[ 2m_{t+b} F_{LL}
+ m_b (F_{LD} - F_{RD}) \right] + N^- \sqrt{s} \left[ 2m_{t+b} F_{LL}
+ \frac{m_b}{s} (c_+ s_t F_{RL} - k_2 F_{LD}) - k_1 F_{RD} \right] \right\},
\]
\[
\mathcal{H}_{-++} = k_0 c_+ \left\{ -N^+ \sqrt{s} \left[ 2m_{t+b} F_{LL}
+ \frac{m_b}{s} (c_+ s_t F_{RL} + k_2 F_{LD}) + k_1 F_{RD} \right]
- N^- c_- s_t \left[ F_{RL} + m_b (F_{LD} - F_{RD}) \right] \right\}
\]

Notation specific to Eq. (13) is:
\[
k_0 = V \chi(M_w^2, s) N^2 N_{(3,2)}^-,
\]
\[
k_1 = 2s_{tb} - c_+ s_t,
\]
\[
k_2 = 2s_{tb} m_t + c_+ m_b s_t.
\]

Next we give HAs for the t channel process of annihilation of different flavors; they are simpler than the previous ones.

- Helicity amplitudes for $\bar{b}d \to \bar{t}u$

\[
\mathcal{H}_{-++} = k_0 \sqrt{s} \sin \vartheta \left( \frac{m_b}{s} (F_{LL} - m_b F_{RD}) - F_{RD} \right),
\]
\[
\mathcal{H}_{-++} = -k_0 \left( \frac{m_t m_b c_-}{s} F_{LL} - 2F_{RL}
+ c_+ (m_b F_{LD} + m_t F_{RD}) \right).
\]

In Eqs. (15) and (16)
\[
k_0 = V \chi(M_w^2, s) P^+(s, 0, m_b) P^+(s, 0, m_t),
\]

with a function typical to helicity amplitudes:
\[
P^\pm(s, x, y) = \sqrt{s - (x \pm y)^2}.
\]

3 Infrared regularization by the complex top quark mass.

Infrared divergences associated with interactions of photons with on-mass-shell top legs in the limit of zero width of the top quark may be regularized by any conventional method (photon mass, dimensional
regularisation), but physically they are naturally regularized by the presence of the finite top quark width $\Gamma_t$. Here this approach will be exploited.

3.1 Top quark width and virtual QED correction

There are three diagrams contributing to virtual one-loop QED corrections involving the top quark: see Figs. 9, 10 and 11.

Fig. 9. The self-energy photonic QED correction for $t\bar{b}d \rightarrow 0$ processes

Fig. 10. The vertex photonic QED correction

The appropriate formalism was developed in Ref. [2]. In particular, it was shown that of the four scalar form factors $F$ only $F_{LL}$ contains IRD QED as well as weak contributions which can be separated thus:

$$F_{LL} = 1 + \frac{e^2}{16\pi^2} \tilde{F}^{\text{QED}}_{LL} + \frac{g^2}{16\pi^2} \tilde{F}^{\text{weak}}_{LL}$$

and the expression for $\tilde{F}^{\text{QED}}_{LL}$ was explicitly expressed in terms of standard Passarino–Veltman (PV) functions $C_0$. To regulate the amplitude the photon was given a mass $\lambda$. However, one can alternatively introduce the top quark width, i.e. instead of

$$C_0 (-m_t^2, -m_b^2, Q^2; m_t, \lambda, m_b)$$

we now write

$$C_0 (-m_t^2, -m_b^2, Q^2; \tilde{m}_t, 0, m_b)$$

with $\tilde{m}_t^2 = m_t^2 + \Delta_t$, $\Delta_t = -im_t \Gamma_t$.

The corresponding replacement for the IRD term due to Fig. 9 reads

$$\ln \left( \frac{m_t^2}{\lambda^2} \right) \rightarrow -2 \frac{\tilde{m}_t^2}{m_t^2} \ln \left( \frac{-im_t \Gamma_t}{\tilde{m}_t^2} \right).$$

The expression for the amplitude of Fig. 11 contains an infrared and mass singular $D_0$ function. In Ref. [18] we have shown that these functions can be reduced by standard Passarino–Veltman reduction to an infrared finite mass singular auxiliary function $J_{AW}^F$ and a mass singular $C_0$ function. This has become standard SANC approach which we apply here.

The relevant $C_0$ function is

$$C_0^{\text{IR}} = C_0 (-m_t^2, -m_b^2, Q^2; \tilde{m}_t, 0, m_b)$$
where

\[ B_d = Q^2 + m_t^2 - m_b^2 + Q^2/|Q|^2 i\varepsilon, \]

\[ S_d = \sqrt{(Q^2)^2 + 2Q^2(m_t^2 + m_b^2) + (m_t^2 - m_b^2)^2}, \]

\[ y_{d1} = \frac{B_d - S_d}{2Q^2}, \quad y_{d2} = \frac{B_d + S_d}{2Q^2}, \]

and

\[ B_l = Q^2 + \tilde{m}_t^2 - m_b^2, \]

\[ S_l = \sqrt{(Q^2)^2 + 2Q^2(\tilde{m}_t^2 + m_b^2) + (\tilde{m}_t^2 - m_b^2)^2}, \]

\[ y_{d1} = \frac{B_l - S_l}{2Q^2}, \quad y_{d2} = \frac{B_l + S_l}{2Q^2}. \]

Its limit for \( m_b \to 0 \) is

\[ C_{0}^{\text{IR}} = \frac{1}{B_d} \left\{ \ln \left( \frac{\Delta_t}{B_l} \right) \ln \left( \frac{m_b^2}{m_t^2} \right) - 2 \ln \left( \frac{B_d}{m_t^2} \right) \ln \left( \frac{\Delta_t}{m_t^2} \right) \right. \]

\[ + \left[ \frac{1}{2} \ln \left( \frac{B_d}{m_t^2} \right) + \ln \left( \frac{B_l}{m_b^2} \right) \right] \ln \left( \frac{B_d}{m_b^2} \right) \]

\[ - \text{Li}_2 \left( -\frac{\Delta_t}{B_l} \right) + \text{Li}_2 \left( -\frac{\Delta_t}{B_t} \right) \]

\[ - \text{Li}_2 \left( \frac{\Delta_t}{B_l} \right) - \text{Li}_2 \left( \frac{Q^2}{B_l} \right) + \zeta(2) \right\}. \]

\[ B_l = Q^2 + \tilde{m}_t^2, \]

\[ B_d = Q^2 + m_t^2 - i\varepsilon. \]

### 3.2 Top quark width and hard photon radiation

We must also consider the amplitude with real photon emission off the \( t \) quark, see Fig. 12. This amplitude involves a propagator with denominator

\[ (p_2 - p_5)^2 + m_t^2 - i m_t \Gamma_t \]

which evaluates to \( z_2 = -2p_2 \cdot p_5 \).

The amplitude of the hard photon radiation process without taking account of the top quark width can be presented in the following form:

\[ A_\gamma^{(0)} = A_t^{(0)} + A_{ad\bar{t}b}W. \]

Here \( A_t^{(0)} \) is the amplitude of the radiating top quark and \( A_{ad\bar{t}b}W \) is the rest. The amplitude \( A_\gamma^{(0)} \) is gauge invariant: \( A_\gamma^{(0)} \cdot p_5 = 0. \)

One can define the amplitude of the hard photon radiation process taking account of the top quark width as

\[ A_\gamma = A_t + A_{ad\bar{t}b}W = \frac{z_2}{z_2 - im_t\Gamma_t} A_t^{(0)} + A_{ad\bar{t}b}W. \]

where the top quark propagator with width \( \Gamma_t \) was introduced.

The amplitude \( A_\gamma \) destroys gauge invariance:

\[ A_\gamma \cdot p_5 \neq 0. \] The gauge violation is of order \( \Gamma_t/m_t. \)
To recover gauge invariance one can modify the amplitude (28) in the following way:

$$\mathcal{A}_g \rightarrow \mathcal{A}_g' = \frac{z_2}{z_2 - i m_t T^a_1} \mathcal{A}^{(0)}_g$$

$$= \frac{z_2}{z_2 - i m_t T^a_1} \left[ \mathcal{A}^{(0)}_g + \mathcal{A}_{udbW} \right]. \quad (29)$$

Such transformation (called overall scheme, (o)) obviously leads to gauge invariance and the mod-squared amplitude will have the form

$$|\mathcal{A}_{\text{over}}^g|^2 = \frac{z_2^2}{z_2^2 + m_t^2 T^a_1^2} \left\{ |\mathcal{A}^{(0)}_g|^2 + \left[ (\mathcal{A}^{(0)}_g)^* \mathcal{A}_{udbW} + \mathcal{A}^{(0)}_g (\mathcal{A}_{udbW})^* \right] \right\} + |\mathcal{A}_{udbW}|^2. \quad (30)$$

As is seen from equation (30), all terms are now regularized by the top quark width but the last term is multiplied by an artificial factor which cannot be treated in the soft (Born-like) kinematics.

To avoid the problem with integration one can introduce a new gauge non-invariant amplitude (which we call fixed scheme (f1)):

$$|\mathcal{A}_{\text{fixed}_1}^g|^2 = \frac{z_2^2}{z_2^2 + m_t^2 T^a_1^2} |\mathcal{A}^{(0)}_g|^2$$

$$+ 2 \text{Re} \frac{z_2}{z_2 - i m_t T^a_1} \mathcal{A}^{(0)}_g (\mathcal{A}_{udbW})^*$$

$$+ |\mathcal{A}_{udbW}|^2. \quad (31)$$

An alternative version, called fixed2, obtains by setting equal to one the coefficient of $|\mathcal{A}_{udbW}|^2$ in Eq. (30):

$$|\mathcal{A}_{\text{fixed}_2}^g|^2 = \frac{z_2^2}{z_2^2 + m_t^2 T^a_1^2} |\mathcal{A}^{(0)}_g|^2 + \left[ (\mathcal{A}^{(0)}_g)^* \mathcal{A}_{udbW} + \mathcal{A}^{(0)}_g (\mathcal{A}_{udbW})^* \right] + |\mathcal{A}_{udbW}|^2. \quad (32)$$

In the next chapter we present numerical results for all width schemes introduced above in order to estimate the numerical impact of gauge violation in fixed schemes.

### 4 Numerical Results

In this section we present the SANC results for the cross sections of single top quark production and for the decay widths of the top quark. The tree level contributions, both Born and single real photon emission, are compared with CompHEP [19]. All numerical results for this section were produced with the standard SANC input working in the $\alpha(0)$ EW scheme, if not stated otherwise.

The standard SANC input parameters set reads:

$$G_F = 1.16637 \times 10^{-5} \text{ GeV}^{-2},$$
$$\alpha(0) = 1/137.035999, \quad \alpha_s = 0.00729735257,$$
$$M_W = 80.403 \text{ GeV}, \quad \Gamma_W = 2.141 \text{ GeV},$$
$$M_Z = 91.1876 \text{ GeV}, \quad \Gamma_Z = 2.4952 \text{ GeV},$$
$$M_H = 120 \text{ GeV}, \quad m_t = 174.2 \text{ GeV},$$
$$m_u = 62 \text{ MeV}, \quad m_d = 83 \text{ MeV},$$
$$m_c = 1.5 \text{ GeV}, \quad m_s = 215 \text{ MeV},$$
$$m_t = 174.2 \text{ GeV}, \quad m_b = 4.7 \text{ GeV},$$
$$|V_{ud}| = 1, \quad |V_{cd}| = 1,$$
$$|V_{us}| = 0, \quad |V_{cs}| = 0,$$
$$|V_{tb}| = 1. \quad (33)$$
This section is subdivided into three subsections: for
the decay channel, s channel and t channel; for the latter
subprocesses results for both direct \((bu \rightarrow td)\) and
crossed \((bd \rightarrow tu)\) channels are presented separately.

Each subsection, in turn, consists of two paragraphs.
The first paragraphs contain a comparison with Comp-
HEP of the Born cross section and of the hard photon
contribution with a cut on photon energy \(E_\gamma\) in the
rest frame of the top (for decay channel) and in the
cms of the initial particles for s and t channels.

In the second paragraphs we present a study of
complete EWRC at the partonic level. We show the
decay widths for the decay channel and cross sections
for the reactions at the tree and one-loop levels. The
one-loop EWRC is defined as usual:

\[
\delta = \frac{\mathcal{O}^{1\text{loop}} - \mathcal{O}^{\text{tree}}}{\mathcal{O}^{\text{tree}}},
\]

where \(\mathcal{O}\) is either width (\(\Gamma\)) or cross section (\(\sigma\)).

Furthermore, the dimensionless soft-hard separator \(\bar{\omega}\)
subdivides soft and hard real photon contributions.
Their sum does not depend on \(\bar{\omega}\).

For decays \(a \rightarrow b + c + d + \gamma\) with \(s = -(p_a - p_b)^2\)
and \(s' = M_{c,d}^2\) and for the processes, \(a + b \rightarrow c + d + \gamma\)
with \(s = M_{a,b}^2\) and \(s' = M_{c,d}^2\)

\[
\bar{\omega} = 1 - \frac{s'}{s}, \quad \text{and} \quad E_\gamma \geq \frac{s}{2} \bar{\omega}.
\]

For each of the four channels we present Tables illustrating
the existence of an \(E_\gamma (\bar{\omega})\) stability plateau
for two options \(\Gamma_t = 0, \neq 0\), and answering the question
how big the difference is of the EWRC between
the two \(\Gamma_t\) options. For reactions, we also investigate
the question of the initial quark masses \((m_q)\) indepen-
dence of the subtracted quantities.

For the explanation of the necessity of the subtrac-
tion procedure and its realization in the \(\overline{\text{MS}}\) scheme
within SANC we refer to our earlier papers \([20] - [21]\).

4.1 Decay Channel \(t \rightarrow b + u + \bar{d}\)

4.1.1 SANC–CompHEP comparison

No new comparison for this channel was done com-
pared to Ref. \([2]\). If the top quark width is taken into
account, SANC and CompHEP numbers agree well.

4.1.2 One-loop EW corrections

Process \(t \rightarrow b + \mu^+ + \bar{\nu}_\mu\).

| \(\Gamma^{\text{Born}} = 0.1490949(2)\) GeV | \(\Gamma_t = 0\) |
|-----------------|-----------------|
| \(E_\gamma\), GeV | \(10^{-1}\) | \(10^{-2}\) | \(10^{-3}\) |
| \(\Gamma^{1\text{loop}}\) | 0.159503(1) | 0.159495(2) | 0.159499(7) |
| \(\delta\) | 6.981(1) | 6.975(1) | 6.978(5) |
| \(\Gamma_t \neq 0, \text{fixed}\) |
| \(\Gamma^{1\text{loop}}\) | 0.160736(2) | 0.160784(2) | 0.160787(8) |
| \(\delta\) | 7.810(1) | 7.841(2) | 7.842(5) |

Table 1. The total lowest-order and one-loop corrected
widths \(\Gamma^{\text{Born}}\) and \(\Gamma^{1\text{loop}}\) in GeV and relative one-loop correction
\(\delta\) in % for \(E_\gamma = 10^{-1}, 10^{-2}, 10^{-3}\) GeV.
As is seen from Table 1, there is good stability for \( E_\gamma \leq 10^{-2} \) GeV and about +0.9% increase of the EWRC for this partial decay width if one uses \( \Gamma_t \neq 0 \) option as compared to the \( \Gamma_t = 0 \) one.  

Process \( t \to b + u + \bar{d} \).  

\[
\Gamma_{\text{Born}} = 0.4472847(7) \text{ GeV}
\]

\[
\begin{array}{|c|c|c|c|}
\hline
E_\gamma, \text{ GeV} & 10^{-1} & 10^{-2} & 10^{-3} \\
\hline
\Gamma^\text{1loop} & 0.47922(1) & 0.47920(1) & 0.47918(1) \\
\hline
\delta & 7.139(1) & 7.135(1) & 7.131(3) \\
\hline
\Gamma_t \neq 0, \text{ fixed}_1 & & & \\
\hline
\Gamma^\text{1loop} & 0.48293(1) & 0.48312(1) & 0.48311(1) \\
\hline
\delta & 7.969(1) & 8.012(1) & 8.010(2) \\
\hline
\end{array}
\]

Table 2. The same but for \( t \to b + u + \bar{d} \) process.  

As is seen from Table 2, one can draw similar conclusions for both considered partial decay channels.  

4.2 \( s \) channel  

There are two generic \( s \) channel processes:  
\[
d + u \to b + t, \quad \text{and} \quad \bar{u} + d \to \bar{t} + b. \quad (36)
\]

4.2.1 SANC–CompHEP comparison  

It is sufficient to consider only one: \( \bar{u} + d \to \bar{t} + b \). For this comparison we use the CompHEP (v. 4.5.1) setup with a cut on the cms photon energy \( E_\gamma \geq 2 \) GeV.  

| \( \sqrt{s}/\text{GeV} \) | ws | 200 | 1000 | 7000 |
|---------------------|-----|-----|------|------|
| \( \Gamma_t = 0 \) |
| CompHEP           | 8.172(1) | 17.19(1) | 0.7966(2) |
| SANC              | 8.173(1) | 17.19(1) | 0.7964(1) |
| \( \Gamma_t = 1.54688 \) GeV |
| CompHEP           | 7.835(1) | 16.93(1) | 0.7882(1) |
| SANC              | 7.834(1) | 16.93(1) | 0.7885(1) |
| \( \Gamma_t \neq 0, \text{ fixed}_1 \) |
| CompHEP           | 7.788(1) | 16.91(1) | 0.7884(1) |
| SANC              | 7.787(1) | 16.91(1) | 0.7884(1) |

Table 3. Comparison of the cross section \( \sigma_{\text{hard}}(\sqrt{s}, \omega) \) (fb) for three cms energies, two options: \( \Gamma_t = 0, \neq 0 \), and three width schemes (ws): o-overall, f-fixed (f\(_1\)(2)=fixed\(_1\)(2) for the case of SANC).  

As is seen from Table 3 there is good agreement of numbers obtained from SANC and CompHEP within the statistical errors for all considered options and cms energies. It is worth to note that the two versions of width schemes agree well for all energies except near the threshold and that the fixed\(_1\) scheme agrees with the CompHEP fixed scheme as expected.  

4.2.2 One-loop EW corrections  

The numbers of this subsection are produced with SANC setup, Eq. (33). The aim is to demonstrate the intervals of stability of one-loop corrected EW cross sections \( \sigma^{\text{1loop}} \) and relative EWRC \( \delta \) against variation
of the soft-hard separation parameter, $\bar{\omega}$, and to study
the difference between the two options: $\Gamma_t = 0, \neq 0$.

$$\sqrt{s} = 200 \text{ GeV}, \sigma^{\text{Born}} = 0.30809055(1) \text{ pb}$$

| $\bar{\omega}$ | $10^{-4}$ | $10^{-5}$ | $10^{-6}$ |
|----------------|----------|----------|----------|
| $\sigma^{\text{1-loop}}$ | 0.315169(2) | 0.315167(3) | 0.315167(4) |
| $\delta$ | 2.297(1) | 2.297(1) | 2.297(1) |

$\Gamma_t \neq 0, \text{ fixed}$

| $\sigma^{\text{1-loop}}$ | 0.315469(2) | 0.315471(3) | 0.315472(3) |
| $\delta$ | 2.395(1) | 2.396(1) | 2.396(1) |

Table 4. The total lowest-order cross sections $\hat{\sigma}^{\text{Born}}$, the
one-loop corrected cross sections $\hat{\sigma}^{\text{1-loop}}$ in pb and relative
corrections $\delta$ in % at three values of $\bar{\omega} = 10^{-4}, 10^{-5}, 10^{-6}$
and two of $\Gamma_t$.

$$\sqrt{s} = 1000 \text{ GeV}, \sigma^{\text{Born}} = 0.105977185(2) \text{ pb}$$

| $\bar{\omega}$ | $10^{-4}$ | $10^{-5}$ | $10^{-6}$ |
|----------------|----------|----------|----------|
| $\sigma^{\text{1-loop}}$ | 1.5917(1) | 1.5917(2) | 1.5919(1) |
| $\delta$ | -28.79(1) | -28.80(1) | -28.78(1) |

$\Gamma_t \neq 0, \text{ fixed}$

| $\sigma^{\text{1-loop}}$ | 1.5815(1) | 1.5895(2) | 1.5895(2) |
| $\delta$ | -29.25(1) | -28.89(1) | -28.89(1) |

Table 5. The same but for $\sqrt{s} = 1000 \text{ GeV}$.

Tables 4–6 were computed with three values of $\bar{\omega}$ and for two options $\Gamma_t = 0, \neq 0$. As far as $\bar{\omega}$-stability is concerned, we see that it depends on the $\Gamma_t$-option.

$$\sqrt{s} = 7000 \text{ GeV}, \sigma^{\text{Born}} = 2.23529503(4) \text{ fb}$$

| $\bar{\omega}$ | $10^{-4}$ | $10^{-5}$ | $10^{-6}$ |
|----------------|----------|----------|----------|
| $\sigma^{\text{1-loop}}$ | 1.5917(1) | 1.5917(2) | 1.5919(1) |
| $\delta$ | -28.79(1) | -28.80(1) | -28.78(1) |

$\Gamma_t \neq 0, \text{ fixed}$

| $\sigma^{\text{1-loop}}$ | 1.5815(1) | 1.5895(2) | 1.5895(2) |
| $\delta$ | -29.25(1) | -28.89(1) | -28.89(1) |

Table 6. The same but for $\sqrt{s} = 7000 \text{ GeV}$ and for $\bar{\omega} = 10^{-5}, 10^{-6}, 10^{-7}$ and the cross sections given in fb.

For $\Gamma_t = 0$ there is stability for all considered $\sqrt{s}$ and $\bar{\omega}$. For $\Gamma_t \neq 0$ it depends on the cms energy $\sqrt{s}$: for 200 GeV stability sets in already at $\bar{\omega} = 10^{-4}$, for 1000 GeV at $\bar{\omega} = 10^{-5}$ and for 7000 GeV at $\bar{\omega} = 10^{-6}$.

$$\sqrt{s} = 200 \text{ GeV}, \Gamma_t = 0$$

| $\bar{\omega}$ | $10^{-4}$ | $10^{-5}$ | $10^{-6}$ |
|----------------|----------|----------|----------|
| $\sigma^{\text{1-loop}}_{\text{MS}}$ | 0.328077(2) | 0.328082(4) | 0.328083(4) |
| $\delta^{\text{MS}}$ | 6.487(1) | 6.489(1) | 6.489(1) |

$\Gamma_t \neq 0, \text{ fixed}$

| $\sigma^{\text{1-loop}}_{\text{MS}}$ | 0.328073(2) | 0.328078(2) | 0.328076(3) |
| $\delta^{\text{MS}}$ | 6.486(1) | 6.488(1) | 6.487(1) |

Table 7. The total one-loop corrected $\overline{\text{MS}}$ subtracted
quantities $\hat{\sigma}^{\text{MS}}$ in pb and corresponding $\delta^{\text{MS}}$ in % at $\bar{\omega} = 10^{-4}, 10^{-5}, 10^{-6}$, respectively. Subscript 1 means that light quark masses are used as in Eq. (33), while 2 means that 10 times smaller masses are used.
However, one can see that the difference between the two options, although it persists, is of order 1 per mille in absolute deviation, which is well below any reasonable estimate of the theoretical uncertainty. We therefore conclude that one may use the usual infrared regularization for $\tau$ channel processes.

The numbers of Tables 7–9 were produced with the aim to demonstrate the independence from light quark masses of the subtracted quantities, $\hat{\sigma}^{\overline{MS}}$ and $\delta^{\overline{MS}}$ for $\Gamma_t = 0$ option at three cms energies. One sees that the light quark mass independence holds in all considered cases at the level much lower than 1 per mille, which is quite sufficient for practical applications.

\begin{table}[h]
\centering
\begin{tabular}{|c|c|c|c|}
\hline

\hline
\end{tabular}
\caption{The same but for $\sqrt{s}=1000$ GeV.}
\end{table}

4.3 $t$ channel

4.3.1 SANC–CompHEP comparison

This is the most complicated case: $t$ channel cross sections usually show up bad statistical convergence. For this comparison we use the CompHEP (v.4.5.1) setup, but with non-zero masses of the $u$ and $d$ quarks (accessed via $bc \rightarrow ts\gamma$ channel). For the Tables of this subsection we used $m_u = m_d = m_q = 66$ MeV, and $10m_q$ means $m_u = m_d = 660$ MeV. The cut on the cms photon energy was $E_\gamma \geq 2$ GeV.

Furthermore, rows marked “SANC(S)” were computed retaining $m_q$ or $10m_q$ only in fermion propagators radiating a photon, while “SANC(F)” means that light quark masses were kept everywhere (“F”ully massive case). Table 11 contains the same information as Table 10 but for the process $b + \bar{d} \rightarrow t + \bar{u}$.

Let us discuss the results of Tables 10, 11 which are qualitatively the same, so we need not refer to the Table number.

Two options ($\Gamma_t = 0, \neq 0$) $\otimes (m_q)$ (4 upper rows) show very good agreement at the threshold, $\sqrt{s} = 200$ GeV, and a notable deviation at TeV energies. We assumed that this is due to the mass singular origin of external light quark lines emitting photons, which obviously is getting worse at high energies. In this con-
Table 10. Comparison of the cross section $\sigma^{\text{hard}}(\sqrt{s}, \bar{\omega})$, fb for the process $b + u \rightarrow t + d$ for three cms energies; four options: $(\Gamma_t = 0, \neq 0) \otimes (m_q, 10m_q)$; and fixed width scheme (ws): $(f_1 = \text{fixed};$ for the case of SANC).

do agree. It is easy to understand why with the latter options the situation near the threshold is not so ideal. In SANC we want to neglect terms with power dependence on light quark masses, keeping only those that would lead to mass singularities. Relatively large masses, $10m_q$, start to matter near the threshold. (Note also that on passing to the hadronic level we will need to subtract mass quark singularities anyway: see next subsection).

To check this assumption we considered the fully massive variant SANC(F) with options $(\Gamma_t = 0, \neq 0) \otimes$
(10m_q) and only at $\sqrt{s} = 200$ GeV. As is seen from the SANC(F) rows of the Tables, the good agreement with CompHEP is recovered.

Although SANC(F) is identical to CompHEP, we prefer to use the much faster SANC(S) version of the code since the masses of u, d and s quarks are very small. The only exception is the c quark whose mass effect will be obviously notable near the threshold. Since we possess the SANC(F) version of the code, we can use a mixed variant with only c quark mass dependence retained.

To conclude this section, we note that the results for the charge conjugate channels are identical to those we have considered:

\[ \bar{b} + \bar{u} \rightarrow \bar{t} + \bar{d} \text{ to } b + u \rightarrow t + d, \]
\[ \bar{b} + d \rightarrow \bar{t} + u \text{ to } b + \bar{d} \rightarrow t + \bar{u}. \]  

(37)

### 4.3.2 One-loop EW corrections, process $bu \rightarrow td$

The numerical results for this subsection were again produced with the SANC setup, Eq. (33), with the same aim to demonstrate the stability of one-loop corrected EW cross sections $\sigma^{1\text{loop}}$ and relative EWRC $\delta$ against variation of the soft-hard separator $\bar{\omega}$ and to study the difference between the two options: $\Gamma_t = 0, \neq 0$.

Tables 12, 13 were computed with three values of $\bar{\omega}$ and for two options $\Gamma_t = 0, \neq 0$. As is seen, the intervals of $\bar{\omega}$-stability depend on $\sqrt{s}$. The higher the cms energy, the lower are the values of $\bar{\omega}$ required to reach stability. For $\sqrt{s}=200$ GeV, stability starts at $\bar{\omega} = 10^{-4}$, for $\sqrt{s}=1000$ GeV at $\bar{\omega} = 10^{-5}$ and for $\sqrt{s}=7000$ TeV it depends additionally on the $\Gamma_t$ option. For $\Gamma_t = 0$ stability starts at $\bar{\omega} = 10^{-6}$ but

| $\sqrt{s}=200$ GeV, $\sigma^{\text{Born}}=7.3551155(1)$ pb | $\Gamma_t = 0$ |
|---|---|---|
| $\bar{\omega}$ | $10^{-4}$ | $10^{-5}$ | $10^{-6}$ |
| $\delta^{1\text{loop}}$ | 7.81964(2) | 7.81954(4) | 7.81956(4) |
| $\delta$ | 6.3156(3) | 6.3144(5) | 6.3146(6) |

| $\Gamma_t \neq 0$, fixed |
|---|---|---|
| $\delta^{1\text{loop}}$ | 7.81954(2) | 7.81956(3) | 7.81957(4) |
| $\delta$ | 6.3143(3) | 6.3145(4) | 6.3147(5) |

**Table 12.** The total lowest-order cross sections $\sigma^{\text{Born}}$, the one-loop corrected cross sections $\sigma^{1\text{loop}}$ in pb and relative one-loop correction $\delta$ in % at three values of $\bar{\omega} = 10^{-4}, 10^{-5}, 10^{-6}$ and two values of $\Gamma_t$.

| $\sqrt{s}=1000$ GeV, $\sigma^{\text{Born}}=48.99340951(6)$ pb | $\Gamma_t = 0$ |
|---|---|---|
| $\bar{\omega}$ | $10^{-5}$ | $10^{-6}$ | $10^{-7}$ |
| $\delta^{1\text{loop}}$ | 53.344(1) | 53.345(1) | 53.346(1) |
| $\delta$ | 8.880(1) | 8.881(2) | 8.883(2) |

| $\Gamma_t \neq 0$, fixed |
|---|---|---|
| $\delta^{1\text{loop}}$ | 53.292(1) | 53.293(1) | 53.293(1) |
| $\delta$ | 8.773(1) | 8.776(2) | 8.776(2) |

**Table 13.** The same but for $\sqrt{s}=1000$ GeV and for $\bar{\omega} = 10^{-5}, 10^{-6}, 10^{-7}$.
The numbers of the Tables 14–15 were produced with the aim to demonstrate the light quark mass independence of the one-loop subtracted quantities $\hat{\sigma}^{\text{\Lambda\overline{MS}}}$ and $\hat{\delta}^{\text{\Lambda\overline{MS}}}$ for the $\Gamma_t \neq 0$ option at three cms energies and three values of $\bar{\omega}$.

The stability of $\hat{\sigma}^{\text{\Lambda\overline{MS}}}$ and $\hat{\delta}^{\text{\Lambda\overline{MS}}}$ seen in Tables 15–16 is a very important check of the correctness of implementation of the complete EWRC and of the initial quark mass singularity subtraction. The latter is crucial at the envisaged stage of going to the hadron level, i.e. convolution with parton density functions.

### Table 14
- For $\sqrt{s}=7000$ GeV and $\bar{\omega} = 10^{-6}, 10^{-7}, 10^{-8}$.
- For $\Gamma_t \neq 0$ only at $\bar{\omega} = 10^{-7}$. However, one can see that the difference between the two options, although it persists, is well below 1 per mille in absolute deviation at lower energies, reaching 1 per mille only at $\sqrt{s}=7000$ GeV, that is the difference under study is below any reasonable estimate of the theoretical uncertainty. We therefore conclude that one may use the usual infrared regularization also for $t$ channel processes.

| $\sqrt{s}=7000$ GeV, $\sigma^{\text{Born}}=50.82423111(8)$ pb | $\Gamma_t = 0$ |
|---|---|
| $\bar{\omega}$ | $10^{-6}$ | $10^{-7}$ | $10^{-8}$ |
| $\hat{\sigma}^{\text{1loop}}$ | 55.696(2) | 55.697(2) | 55.697(2) |
| $\hat{\delta}$ | 9.586(3) | 9.588(4) | 9.587(4) |

### Table 15
- The total one-loop corrected $\overline{\text{MS}}$ subtracted quantities (see text) $\hat{\sigma}^{\text{\Lambda\overline{MS}}}$ in pb and corresponding $\hat{\delta}^{\text{\Lambda\overline{MS}}}$ in % at $\bar{\omega} = 10^{-4}, 10^{-5}, 10^{-6}$. Sub-index 1 means that light quark masses used are as in Eq. (33), while 2 means that 10 times lower masses are used.

| $\sqrt{s}=200$ GeV, $\sigma^{\text{Born}}=7.3551155(1)$ pb | $\Gamma_t = 0$ |
|---|---|
| $\bar{\omega}$ | $10^{-4}$ | $10^{-5}$ | $10^{-6}$ |
| $\hat{\sigma}_1^{\text{\Lambda\overline{MS}}}$ | 8.09370(2) | 8.09377(4) | 8.09380(4) |
| $\delta_1^{\text{\Lambda\overline{MS}}}$ | 10.042(1) | 10.043(1) | 10.043(1) |
| $\hat{\sigma}_2^{\text{\Lambda\overline{MS}}}$ | 8.09116(4) | 8.09127(6) | 8.09129(8) |
| $\delta_2^{\text{\Lambda\overline{MS}}}$ | 10.043(1) | 10.045(1) | 10.045(1) |

### Table 16
- The same but for $\sqrt{s}=1000$ GeV and for $\bar{\omega} = 10^{-5}, 10^{-6}, 10^{-7}$.

| $\sqrt{s}=1000$ GeV, $\sigma^{\text{Born}}=48.99340953(6)$ pb | $\Gamma_t = 0$ |
|---|---|
| $\bar{\omega}$ | $10^{-5}$ | $10^{-6}$ | $10^{-7}$ |
| $\hat{\sigma}_1^{\text{\Lambda\overline{MS}}}$ | 53.416(1) | 53.416(1) | 53.417(1) |
| $\delta_1^{\text{\Lambda\overline{MS}}}$ | 9.027(1) | 9.028(2) | 9.030(2) |
| $\hat{\sigma}_2^{\text{\Lambda\overline{MS}}}$ | 53.416(1) | 53.416(1) | 53.417(2) |
| $\delta_2^{\text{\Lambda\overline{MS}}}$ | 9.029(2) | 9.029(2) | 9.032(3) |
Here we repeat the study of subsection 4.3.2, but now for the crossed \( t \) channel. Tables 18–20 are analogous to Tables 12–14. They demonstrate the stability of \( \sigma_{\text{Born}} \) and the difference between the options \( \Gamma_t = 0, \neq 0 \).

Tables 18–20 show up properties very similar to the Tables for the direct \( t \) channel. Each Table shows the presence of a plateau of stability in \( \bar{\omega} \) and the same level of difference between calculations for two options \( \Gamma_t = 0, \neq 0 \), qualitatively with very similar energy dependence.

### Subtraction of quark mass singularities

The numbers of Tables 21–23 were also produced with the aim to demonstrate the light quark mass independence of the subtracted quantities \( \sigma^{\text{MS}} \) and \( \delta^{\text{MS}} \) for option \( \Gamma_t = 0 \) at three cms energies.

### Again, Tables 21–23

Although within larger statistical errors, show the stability of \( \sigma^{\text{MS}} \) and \( \delta^{\text{MS}} \) for all cms energies and \( \bar{\omega} \) values considered, confirming the correctness of implementation of the complete EWRC also for the case of the crossed \( t \) channel.

The total one-loop corrected $\overline{\text{MS}}$ subtracted quantities $\hat{\sigma}^{\text{MS}}_i$ in pb and corresponding $\delta^{\text{MS}}_i$ in % at $\bar{\omega} = 10^{-4}, 10^{-5}, 10^{-6}$. Sub-index 1 means that light quark masses used are as in Eq. (33), while 2 means that 10 times lower masses are used.

5 Conclusions and Outlook

In this paper we describe the implementation into the SANC framework of the complete one-loop EW calculations, including hard bremsstrahlung contributions, for the processes of the top quark decays a of $s$ and $t$ channel production, the latter two at the partonic level,. The essentially new aspect of this paper is the study of regularisation of the top quark–photon infrared divergences with aid of the complex mass of the top quark. For this reason, we briefly come back to the top decay channels, since this issue was not studied in our previous papers, Ref. [12]. A comparison of these electroweak corrections computed within this new approach with those computed by the con-
ventional method showed a sizable (1%) effect for top decays and only per mille level effect for both considered top production processes. In this paper we limit ourselves to 4-fermion type of processes. For this reason we do not consider $t$ quark production channel in association with $W$ boson. This channel will be presented elsewhere.

We have presented analytical expressions for the covariant amplitude of the process and the helicity amplitudes for three different cross channels within the standard SANC multichannel approach, Ref [17]. In this approach the one-loop covariant amplitude is computed only once for to-the-vacuum-annihilation processes, see Figs. [1] and [2]. To get the CA for a physical channel a cross transformation of external 4-momenta is performed. The helicity amplitudes have been calculated for each channel separately.

Within the SANC framework, we have created the standard FORM and FORTRAN modules, see, Ref. [22], compiled into a package sanc-cc-1.40 which may be downloaded from SANC project homepages. All the calculations were done using a combination of analytic and Monte Carlo integration methods which will make it easy to impose experimental cuts in forthcoming calculations for the $pp$-collisions at LHC, which will be the subject of a subsequent paper.

The emphasis of this paper is to be assured of the correctness of our results. We observe the independence of the form factors on gauge parameters (all calculations were done in $R_{\xi}$ gauge), checked the stability of the result against variation of the soft-hard separation parameter $\bar{\omega}$ and the independence of the $\overline{MS}$ subtracted quantities off the initial quark masses which is crucial for calculations at the hadronic level.

As has become SANC standard, we tried to compare our numerical results for these channels with other independent calculations. For the decay channels it was done in our previous papers (both EW [1] and QCD [23]), showing good agreement. As usual, the Born level and the hard photon contributions of all three channels were checked against CompHEP package and we found very good agreement for both $\Gamma_t = 0, \neq 0$ options.

As far as the comparison of EWRC for the production processes is concerned, the situation is not satisfactory. We did not find in the literature any calculations for the $s$ channel. For the $t$ channel there are many papers, see, for instance, Refs. [12–15] and references therein. The most appropriate is Ref. [12], where however the hard photon contribution is not included. We tried to suppress it in our calculations, but got only rough agreement with their Fig. 3(a). The most advanced paper Ref. [14] contains results at the hadronic level and, at present, we can not yet make a comparison.

The results presented in this papers lay a solid base for subsequent extensions of calculations for the single
top production channels at hadron colliders, basically LHC.
