The approach to equilibrium in a macroscopic quantum system for a typical nonequilibrium subspace

Sheldon Goldstein\textsuperscript{1}, Takashi Hara\textsuperscript{2}, and Hal Tasaki\textsuperscript{3}

Abstract

We study the problem of the approach to equilibrium in a macroscopic quantum system in an abstract setting. We prove that, for a typical choice of “nonequilibrium subspace”, any initial state (from the energy shell) thermalizes, and in fact does so very quickly, on the order of the Boltzmann time $\tau_B := h/(k_BT)$. This apparently unrealistic, but mathematically rigorous, conclusion has the important physical implication that the moderately slow decay observed in reality is not typical in the present setting.

The fact that macroscopic systems approach thermal equilibrium may seem puzzling, for example, because it may seem to conflict with the time-reversibility of the microscopic dynamics. According the present result, what needs to be explained is, not that macroscopic systems approach equilibrium, but that they do so slowly.

Mathematically our result is based on an interesting property of the maximum eigenvalue of the Hadamard product of a positive semi-definite matrix and a random projection matrix. The recent exact formula by Collins for the integral with respect to the Haar measure of the unitary group plays an essential role in our proof.

1 Introduction

Recently there has been a considerable renewed interest in the foundation of quantum statistical mechanics. This has led, in particular, to a revival of the old approach by von Neumann to investigate the problem of thermalization only in terms of quantum dynamics in an isolated system [1, 2]. It has been demonstrated in some general or concrete settings that a pure initial state evolving under quantum dynamics indeed thermalizes (i.e., approaches thermal equilibrium) in a certain mathematical sense\(^4\) [3, 4, 5, 6, 7, 8, 9, 10]. The underlying related idea that a typical pure state of a macroscopic quantum system can fully describe thermal equilibrium has also become much more concrete [11, 12, 13, 14, 15]. An important issue then is to understand the time scale necessary for thermalization [16, 17, 18, 19, 20].

Let us briefly describe the setting and the main result. Precise definitions will be given in later sections. We here follow the approaches of von Neumann [1, 2] and of Goldstein, Lebowitz, Mastrodonato, Tumulka, and Zanghì [6] (see also [7, 18]), and study the problem of the approach to equilibrium of an isolated macroscopic quantum system\(^5\) in an abstract setting.

We consider the energy shell \(\mathcal{H}\), which is a linear space spanned by energy eigenstates corresponding to the narrow energy range \([U - \Delta U, U]\), and assume that nonequilibrium states of the system are characterized by a subspace \(\mathcal{H}_{\text{neq}}\) of \(\mathcal{H}\). We also assume that the dimension \(d\) of \(\mathcal{H}_{\text{neq}}\) is much smaller than the dimension \(D\) of the energy shell \(\mathcal{H}\). We regard states close to \(\mathcal{H}_{\text{neq}}\) as being out of equilibrium and those far from \(\mathcal{H}_{\text{neq}}\) as in equilibrium.

Then the question of the approach to equilibrium is formulated as follows. One starts from an initial state \(\varphi(0) \in \mathcal{H}\) which may be close to \(\mathcal{H}_{\text{neq}}\). One then asks how the expectation value \(\langle \varphi(t), \hat{P}_{\text{neq}} \varphi(t) \rangle\) behaves as a function of time \(t\), where \(\hat{P}_{\text{neq}}\) is the orthogonal projection onto \(\mathcal{H}_{\text{neq}}\) and \(\langle \cdot, \cdot \rangle\) denotes the inner product. If one finds

\(^4\)These rigorous results about thermalization (or equilibration) can be divided into two classes. In the first class, which goes back to [1, 2] and includes [6, 7], one is allowed to take any initial state (from the energy shell). In the second class, which (as far as we know) starts from [3] and includes [4, 5, 8, 9], one uses initial states which have sufficiently broad energy distribution. There is an essential difference in the mechanisms of equilibration in the two classes.

\(^5\)Of course there is no such thing in reality as a completely isolated system. Our motivation for studying isolated systems is basically to learn what physics (including thermodynamic behavior and the approach to equilibrium) can be realized in isolated systems. We can study the roles played by the interaction with surrounding environment after that.
that \( \langle \varphi(t), \hat{P}_{\text{neq}} \varphi(t) \rangle \ll 1 \) for some \( t \), it means that \( \varphi(t) \) is far from \( \mathcal{H}_{\text{neq}} \) and hence in equilibrium.

In reality the subspace \( \mathcal{H}_{\text{neq}} \) should be almost uniquely determined from physical properties of the system. It is not an easy task, however, to characterize \( \mathcal{H}_{\text{neq}} \) in general or in a concrete setting. Nor is it easy to usefully estimate the relaxation time for any specific physical \( \mathcal{H}_{\text{neq}} \). We shall therefore take an abstract approach in which we regard \( \mathcal{H}_{\text{neq}} \) as a general \( d \)-dimensional subspace of \( \mathcal{H} \), and try to elucidate the relation between \( \mathcal{H}_{\text{neq}} \) and the associated relaxation time.

In our previous work [18], we proved via an explicit (and artificial) construction that, depending on the choice of nonequilibrium subspace \( \mathcal{H}_{\text{neq}} \), the relaxation time can be as extremely large as \( h d/\Delta U \), exceeding the age of the universe, or as ridiculously short as \( h/\Delta U \), where \( h \) is Planck’s constant.

This motivates us to study the time scale of thermalization, or, more precisely, that of the escape from the nonequilibrium subspace \( \mathcal{H}_{\text{neq}} \), for various choices of \( \mathcal{H}_{\text{neq}} \). It may be natural to first focus on a setting in which the “nonequilibrium subspace” \( \mathcal{H}_{\text{neq}} \) is not, in fact, a realistic nonequilibrium subspace, but rather is chosen in a completely random manner. One might hope that for such a subspace one generically has a realistic relaxation time. If this were so, it would seem reasonable to believe that the same thing would probably be true for a realistic nonequilibrium subspace (unless we have reasons to expect otherwise). This is basically von Neumann’s philosophy in [1]. Unfortunately this hope turns out to be far too optimistic.

In the present paper we study the setting where \( \mathcal{H}_{\text{neq}} \) is drawn randomly, and prove that, with probability close to one, the expectation \( \langle \varphi(t), \hat{P}_{\text{neq}} \varphi(t) \rangle \) quickly becomes extremely small (when averaged in time) for any initial state \( \varphi(0) \in \mathcal{H} \). This means that any state (including those that are very far from equilibrium) quickly approaches equilibrium, provided that we interpret \( \mathcal{H}_{\text{neq}} \) as the physical nonequilibrium subspace. The time necessary for the thermalization is of order the Boltzmann time \( \tau_B := h/(k_B T) \), which is usually extraordinarily short. At room temperature, for example, \( \tau_B \) is of order \( 10^{-13} \) s. We thus have a mathematically rigorous theorem that basically tells us that our coffee is no longer hot after, say, a micro-second\(^6\)!

This conclusion is of course absurd and highly unphysical\(^7\). But it indeed has the deep physical implication that a realistic system (in which coffee is hot even after a few minutes) are not covered by our theorem. In other words, we can conclude that the moderately slow decay observed in reality is not typical in the present setting, where we draw \( \mathcal{H}_{\text{neq}} \) randomly.

The method of appeal to typicality in quantum physics was (probably) initiated by von Neumann in [1] and played crucial roles in many situations including successful physical applications of the theory of random matrices. The method is clearly summarized

\(^6\)One may remark that our coffee cup is not an isolated quantum system. In this case, one should regard the whole room containing the cup as a single macroscopic system, and assume that it is isolated from the outside world.

\(^7\)It is true, however, that the Boltzmann time \( \tau_B \) is the characteristic time scale for various quantum phenomena.
It means that, if a property is true of most \( H_{\text{neq}} \), this fact may suggest that the property is also true of a concrete given system, unless we have reasons to expect otherwise.

We have now come up with a nontrivial and interesting situation in which the method of typicality does not work as intended. In our case the “property that is true of most \( H_{\text{neq}} \)”, i.e., a very quick decay, turns out to be simply unphysical. Therefore, in order to deal with the problem of thermalization in an isolated quantum system, one can no longer rely on a crude appeal to typicality, but should develop new points of view and methods which take into account some essential features of realistic macroscopic systems. We point out that recent works \([18, 20]\) on the time-scale of thermalization (or equilibration) may contain hints for such future directions. See section 2.3 for further discussions.

From a mathematical point of view, our result is based on the following interesting property about the maximum eigenvalue of the Hadamard product (or the Schur product) of a positive semi-definite matrix and a random projection matrix.

Let \( A = (A_{\alpha\beta})_{\alpha,\beta \in \{1, \ldots, D\}} \) be a \( D \times D \) positive semi-definite matrix with \( A_{\alpha\alpha} \leq 1 \) for all \( \alpha \in \{1, \ldots, D\} \). We denote by \( \mu_{\text{max}} \) the maximum eigenvalue of \( A \). Let \( P = (P_{\alpha\beta})_{\alpha,\beta \in \{1, \ldots, D\}} \) be the projection matrix onto a randomly drawn \( d \)-dimensional subspace, where \( d \ll D \). We define a new matrix \( B \) as their Hadamard product, i.e., \( B_{\alpha\beta} := A_{\alpha\beta} P_{\alpha\beta} \), and denote by \( \lambda_{\text{max}} \) the maximum eigenvalue of \( B \). We then prove a bound for \( \lambda_{\text{max}} \) which roughly implies that \( \lambda_{\text{max}} \lesssim \mu_{\text{max}}/D \) with probability very close to one\(^9\). See Proposition 3.1 for the precise statement.

The recent exact formula by Collins \([21]\) of the integral with respect to the Haar measure of the unitary group plays an essential role in our proof.

In \([17]\), Cramer proved a closely related result, which may be interpreted as an infinite temperature version of ours\(^{10}\).

In a very recent work \([20]\), Malabarba, García-Pintos, Linden, Farrelly, and Short studied the equilibration in quantum systems, and proved, among other things, that most observables equilibrate quite rapidly. This result is of course quite similar to ours\(^{11}\).

\(^{8}\)From Section 6 of \([2]\). We have made small modifications to make the quote consistent with the present discussion.

\(^{9}\)Throughout the present paper, \( A \sim B \) means that \( A/B \) is close to one. \( A \approx B \) means the weaker relation that \( A/B \) is \( O(1) \). Likewise, \( A \lesssim B \) means \( A \leq B' \) with \( B' \sim B \).

\(^{10}\)Cramer considers a random Hamiltonian. Our results apply automatically to the setting where we fix the nonequilibrium subspace and draw the (eigenbasis of the) Hamiltonian randomly. See the remark below Proposition 3.2 for a further relation between Cramer’s work and ours.

\(^{11}\)There are however essential differences between their work and ours. The initial state needs to have a sufficiently broad energy distribution in the former, while it is arbitrary in the latter. The observable is drawn randomly after fixing the initial state in the former, while the random subspace is fixed at the beginning in the latter. The former treats equilibration while the latter deals with thermalization.
The main result of the present paper and the ideas of the proof were already announced in [19].

2 Main result and its implications

2.1 Setting and some background

We consider an abstract model of an isolated macroscopic quantum system in a large volume. A typical example is a system of \(N\) particles confined in a box of volume \(V\), where the density \(N/V\) is kept constant when \(V\) becomes large. In what follows we assume that the volume \(V\) is fixed, and do not discuss the \(V\) dependence of various quantities explicitly.

Let \(\hat{H}\) be the Hamiltonian, and denote by \(E_\alpha\) and \(\psi_\alpha\) the eigenvalues and the normalized eigenstates, respectively, of \(\hat{H}\), i.e.,

\[
\hat{H}\psi_\alpha = E_\alpha\psi_\alpha.
\] (2.1)

We focus on the energy interval \([U - \Delta U, U]\), where \(\Delta U\) denotes a range of energy which is small from the macroscopic point of view but is still large enough to contain many energy levels. The choice of \(\Delta U\) is somewhat arbitrary. It is convenient to relabel the index \(\alpha\) so that the energy eigenvalues \(E_\alpha \in [U - \Delta U, U]\) precisely correspond to the indices \(\alpha \in \{1, \ldots, D\}\). We shall work with the Hilbert space \(\mathcal{H}\) spanned by all \(\psi_\alpha\) with \(\alpha \in \{1, \ldots, D\}\), which is often called the microcanonical energy shell.

Let us briefly describe the problem of the approach to equilibrium, mainly following [2, 6, 7]. We recommend [2] as an accessible exposition.

It has been well established by now that, in a normal macroscopic quantum system, the overwhelming majority of states in the energy shell \(\mathcal{H}\) correspond to the thermal equilibrium state [2, 11, 12, 13].

To formulate this fact mathematically\(^{12}\), we assume that the energy shell \(\mathcal{H}\) is decomposed into the equilibrium and the nonequilibrium subspaces as \(\mathcal{H} = \mathcal{H}_{eq} \oplus \mathcal{H}_{neq}\). We regard any state \(\varphi\) which is close enough to \(\mathcal{H}_{eq}\) as being an equilibrium state, and a state not close to \(\mathcal{H}_{eq}\) as a nonequilibrium state\(^{13}\). Note that neither the set of equilibrium states nor that of nonequilibrium states forms a subspace of \(\mathcal{H}\). We assume that the subspace \(\mathcal{H}_{eq}\) occupies most of the energy shell \(\mathcal{H}\) in the sense that the dimension \(d\) of the nonequilibrium subspace \(\mathcal{H}_{neq}\) satisfies \(d \ll D\). One then easily finds that a typical state in the energy shell is an equilibrium state\(^{14}\).

\(^{12}\)We do not mean that this is the only possible formulation.

\(^{13}\)Consider the simplest situation where one is interested in the behavior of a single macroscopic quantity \(\hat{O}\), whose equilibrium value is \(\bar{O}\). Then one can define \(\mathcal{H}_{eq}\) as the subspace spanned by the eigenstates of the nonnegative operator \((\hat{O} - \bar{O})^2\) corresponding to sufficiently small eigenvalues.

\(^{14}\)Let \(\hat{P}_{neq}\) be the projection onto \(\mathcal{H}_{neq}\), and consider the expectation value \(\langle \varphi, \hat{P}_{neq} \varphi \rangle\). By taking the uniform average over all normalized \(\varphi \in \mathcal{H}\), we get \(E[\langle \varphi, \hat{P}_{neq} \varphi \rangle] = d/D \ll 1\). From the standard argument based on the Markov inequality, we find that \(\langle \varphi, \hat{P}_{neq} \varphi \rangle \ll 1\) for a typical \(\varphi \in \mathcal{H}\). The inequality \(\langle \varphi, \hat{P}_{neq} \varphi \rangle \ll 1\) implies \(\varphi\) is very close to \(\mathcal{H}_{eq}\) and hence is an equilibrium state.
We note that the dimensions $D$ and $d$ usually depend on the volume $V$ as $D \approx e^{\sigma V}$ and $d \approx e^{\sigma' V}$ with constants (entropy densities) $0 < \sigma' < \sigma$. This in particular means that $D$ and $d$ are both huge.

The next question is whether an isolated quantum system evolving under the unitary time evolution exhibits the approach to equilibrium. We assume that the system starts from a normalized initial state $\varphi(0) \in \mathcal{H}$ which may not be close to $\mathcal{H}_{\text{eq}}$, and ask whether its time evolution

$$\varphi(t) = e^{-i\hat{H}t/\hbar}\varphi(0),$$

(2.2)

where $t \geq 0$, comes and stays, for most $t$, very close to $\mathcal{H}_{\text{eq}}$ when $t$ is large.

Let $\hat{P}_{\text{neq}}$ denote the orthogonal projection onto the nonequilibrium subspace $\mathcal{H}_{\text{neq}}$. In some settings (and under suitable assumptions), it has been proved that $[3, 4, 5, 6, 7, 8, 9]$

$$\frac{1}{\tau} \int_0^\tau dt \langle \varphi(t), \hat{P}_{\text{neq}} \varphi(t) \rangle \ll 1$$

(2.3)

for sufficiently large $\tau > 0$. In the present paper we also prove a statement of this type. The bound (2.3) implies that, within the time interval $[0, \tau]$, the state $\varphi(t)$ spends most of the time in the close vicinity of the equilibrium subspace $\mathcal{H}_{\text{eq}}$, i.e., the system approaches equilibrium within the time scale of order $\tau$. See section 2.3.

Let us briefly recall a version of such results proved by Goldstein, Lebowitz, Masatrodonato, Tumulka, and Zanghï [6], who followed the philosophy of von Neumann’s [1, 2]. As we discussed in the introduction, we here regard the nonequilibrium subspace $\mathcal{H}_{\text{neq}}$ as a general $d$-dimensional subspace of $\mathcal{H}$. Then it was proved that, for a typical choice\(^\text{15}\) of $\mathcal{H}_{\text{neq}}$, one has

$$\langle \psi_\alpha, \hat{P}_{\text{neq}} \psi_\alpha \rangle \ll 1$$

(2.4)

for any $\alpha \in \{1, \ldots, D\}$. This is a version of the property usually called “energy-eigenstate thermalization”. By using this property, it was shown that (2.3) is valid for any initial state $\varphi(0) \in \mathcal{H}$.

Although this seems to establish the desired approach to equilibrium, we would also like to have some information about how large $\tau$ should be in (2.3). We have treated this problem of time scale explicitly in [18], and proved two theorems by explicit (and purely mathematical) construction of $\mathcal{H}_{\text{neq}}$; for some choices of $\mathcal{H}_{\text{neq}}$ the required time scale becomes as large as $\tau \approx h d/\Delta U$ which can easily exceed the age of the universe, while for some other choices it becomes as small as $\tau \approx h/\Delta U$ which is ridiculously short.

This observation suggests that our understanding of the approach to equilibrium in isolated quantum systems is still quite primitive. In particular we need to learn more about the time scale required for thermalization.

### 2.2 Assumptions and main result

We shall state our main result precisely in the present subsection.

\(^{15}\)In [6], the authors fix $\mathcal{H}_{\text{neq}}$ and choose the orthonormal basis $\{\psi_\alpha\}_{\alpha \in \{1, \ldots, D\}}$ randomly. But this is equivalent to the present formulation. See also [7].
We assume that the distribution of the energy eigenvalues $E_1, \ldots, E_D \in [U - \Delta U, U]$ is well-described by a single function $\rho(E)$, the density of states. More precisely, we assume\textsuperscript{16} for any differentiable function $f(E)$ that

$$\frac{1}{D} \sum_{\alpha=1}^{D} f(E_\alpha) - \int_{U - \Delta U - \eta}^{U + \eta} dE \rho(E) f(E) \leq \eta \times \sup_{E \in [U - \Delta U - \eta, U + \eta]} |f'(E)|,$$  \hspace{1cm} (2.5)

where $\eta$ is a small constant. See Appendix B for details. Here we take the constant as

$$\eta = D^{-\kappa} \tilde{\beta}^{-1}.$$  \hspace{1cm} (2.6)

where $\kappa < 1$ is a constant close to 1.

We shall make an essential assumption that $\rho(E)$ satisfies

$$\rho(E) \leq \tilde{\beta} D$$ \hspace{1cm} (2.7)

for any $E \in [U - \Delta U - \eta, U + \eta]$. The motivation for this upper bound is explained in Remark 2 at the end of the section. The constant $\tilde{\beta}$ which appears both in (2.6) and (2.7) is interpreted as the inverse temperature $\tilde{\beta} = (k_B T)^{-1}$ corresponding to the equilibrium state in the energy shell. Here $k_B \sim 1.38 \times 10^{-23}$ J/K is the Boltzmann constant and $T$ is the absolute temperature.

We also define the Boltzmann time

$$\tau_B := \hbar \tilde{\beta} = \frac{\hbar}{k_B T},$$ \hspace{1cm} (2.8)

which is a natural time scale associated with the absolute temperature $T$. Here $\hbar = 2\pi \hbar \sim 6.626 \times 10^{-34}$ Js is the Planck constant. Note that the Boltzmann time is extremely short for practical temperatures. For example $\tau_B \approx 1.6 \times 10^{-13}$ s for the room temperature $T \approx 300$ K, and $\tau_B \approx 0.5$ s for $T \approx 10^{-10}$ K, which is the lowest possible temperature that can be achieved in the current ultracold atom experiments.

In order to investigate the properties of a generic “nonequilibrium subspace”, we shall generate a $d$-dimensional subspace of the energy shell $\mathcal{H}$ randomly as follows. In what follows, we denote the random subspace as $\mathcal{H}_{\text{rand}}$ and the corresponding projection as $\hat{P}_{\text{rand}}$ to emphasize that these are random objects. Note that $\mathcal{H}_{\text{rand}}$ is our probabilistic model of $\mathcal{H}_{\text{neq}}$.

By $\mathcal{U}(\mathcal{H})$ we denote the group of all the unitary transformations on $\mathcal{H}$. For each $\hat{U} \in \mathcal{U}(\mathcal{H})$ and $j \in \{1, \ldots, d\}$, we define the normalized state $\xi^{(j)} = \hat{U} \psi_j$. We then consider the $d$-dimensional subspace $\mathcal{H}_{\text{rand}}$ spanned by $\xi^{(1)}, \ldots, \xi^{(d)}$, and the corresponding projection operator

$$\hat{P}_{\text{rand}} = \sum_{j=1}^{d} \hat{p}[\xi^{(j)}],$$ \hspace{1cm} (2.9)

\textsuperscript{16}To be precise (2.5) is not an assumption since it can always be satisfied. See Appendix B. The real assumption, which is contained in (2.7), is that the function $\rho(E)$ behaves as a physical density of states, which is smooth and (almost) monotone increasing.
where $\hat{p}[\xi]$ denotes the orthogonal projection onto $\xi$. By drawing $\hat{U} \in \mathcal{U}(\mathcal{H})$ according to the unique Haar measure on $\mathcal{U}(\mathcal{H})$, we can generate the $d$-dimensional subspace $\mathcal{H}_{\text{rand}}$ and the associated projection $\hat{P}_{\text{rand}}$ in a completely random manner.

Our main finding is summarized in the following theorem. The theorem is proved in section 3 based on Proposition 3.1, which is valid for more general matrices.

**Theorem 2.1** Fix an arbitrary (small) $\varepsilon > 0$. Let the dimension $D$ be sufficiently large and the dimension $d \geq 1$ be sufficiently small compared with $D$. (See the proof for the precise conditions.) Let $\mathcal{H}_{\text{rand}}$ and $\hat{P}_{\text{rand}}$ be the random $d$-dimensional subspace and the corresponding projection as defined above. Then, with probability larger than $1 - \frac{d}{D}$,

$$\frac{1}{\tau} \int_0^\tau dt \langle \varphi(t), \hat{P}_{\text{rand}} \varphi(t) \rangle \leq \frac{\tau B}{\tau} \left(1 + 2D^{-\kappa/5}\right)(1 + \varepsilon) \sim \frac{\tau B}{\tau},$$

(2.10)

for any normalized initial state $\varphi(0) \in \mathcal{H}$, and for any $\tau$ such that

$$0 \leq \frac{\tau}{\tau B} \leq \min \left\{ D^{\kappa/5}, \left( \frac{D}{d} \right)^{1/4} \right\}.$$

(2.11)

**Remarks:** 1. It is expected that, with probability very close to one, the left-hand side of (2.10) converges to $d/D$ for extremely large $\tau$. We can also prove this fact, but do not include the proof in the present paper as the required time scale is unphysically large.

2. Let us explain the motivation for the assumption (2.7). In a macroscopic quantum system, the number of states (i.e., the number of $\alpha$ such that $E_\alpha \leq E$) is well approximated by a function $\Omega(E)$ which is smooth and rapidly increasing in $E$. See, e.g., section 3.5 of [22]. Then the temperature $T$ at energy $U$ is written as

$$\frac{1}{k_B T} = \frac{\partial \log \Omega(E)}{\partial E} \bigg|_{E=U} = \frac{\rho(U)}{\Omega(U)},$$

(2.12)

where $\rho(E) := \Omega'(E)$ is the density of states. By noting that $D = \Omega(U) - \Omega(U - \Delta U) \sim \Omega(U)$, where the approximate equality is generally quite accurate provided that $\Delta U \gg k_B T$, and $\rho(E)$ is generally increasing in $E$, we find

$$\rho(E) \leq \rho(U) = \frac{1}{k_B T} \Omega(U) \sim \frac{D}{k_B T},$$

(2.13)

for any $E \in [U - \Delta U, U]$, which is our assumption (2.7).

3. The assumption $\Delta U \gg k_B T$ in the previous remark is legitimate from a physical point of view. In the unphysical situation with $\Delta U \ll k_B T$, which is easily realized mathematically, the assumption (2.7) is no longer appropriate. Here one expects the density of states $\rho(E)$ to be almost constant within the whole interval $[U - \Delta U, U]$.

---

17The number of states generally behaves as $\Omega(E) \approx \exp[V \sigma(E/V)]$, where the entropy density $\sigma(\epsilon)$ is a strictly increasing convex function.
Thus the assumption (2.7) should be replaced by $\rho(E) \leq D/\Delta U$. Consequently the main inequality (2.10) of Theorem 2.1 is modified as

$$\frac{1}{\tau} \int_0^\tau dt \langle \varphi(t), \hat{P}_{\text{rnd}} \varphi(t) \rangle \lesssim \frac{\hbar}{\Delta U} \frac{1}{\tau},$$

which means that the decay is much slower than in the original setting. See the end of section 2.3 for an interpretation.

4. One may interpret our theorem, which is indeed valid for any $d$ with $1 \leq d \ll D$, as providing information about how fast states vary in a macroscopic quantum system. We find that, with probability close to one, any state (including mixed states) in $\mathcal{H}_{\text{rnd}}$ escapes from $\mathcal{H}_{\text{rnd}}$ on the order of the Boltzmann time.

2.3 Physical implications of the theorem

As we have briefly discussed in section 2.1, our main inequality (2.10) implies that any initial state of the system approaches thermal equilibrium within the time scale $\tau \gg \tau_B$, provided that we regard $\mathcal{H}_{\text{rnd}}$ as a realization of the physical nonequilibrium subspace.

To see this rewrite (2.10) as

$$\frac{1}{\tau} \int_0^\tau dt \langle \varphi(t), \hat{P}_{\text{rnd}} \varphi(t) \rangle \leq \varepsilon_1 \varepsilon_2,$$

where both $\varepsilon_1$ and $\varepsilon_2$ are assumed to be small. Then define the “bad” subset of $[0, \tau]$ by

$$\mathcal{B} := \{ t \in [0, \tau] | \langle \varphi(t), \hat{P}_{\text{rnd}} \varphi(t) \rangle \geq \varepsilon_1 \}.$$  

From (2.15) and the Markov inequality one readily finds that the “total length” (or the Lebesgue measure) $|\mathcal{B}|$ of the subset $\mathcal{B}$ satisfies

$$\frac{|\mathcal{B}|}{\tau} \leq \varepsilon_2,$$

which means that the bad subset $\mathcal{B}$ is a minority in the whole interval $[0, \tau]$. In other words, we have $\langle \varphi(t), \hat{P}_{\text{rnd}} \varphi(t) \rangle \leq \varepsilon_1$ for a typical $t$ (randomly chosen) from $[0, \tau]$. Since small $\langle \varphi(t), \hat{P}_{\text{rnd}} \varphi(t) \rangle$ indicates that the state $\varphi(t)$ is in equilibrium, we conclude that the system equilibrates within time $\tau$, no matter what the initial state $\varphi(0)$ is.

Let us examine how large $\tau$ should be in a realistic setting. Suppose that $T \approx 300$ K, and hence $\tau_B \approx 1.6 \times 10^{-13}$ s. Then even for $\tau \approx 1$ $\mu$s $= 10^{-6}$ s, the right-hand side of (2.10) does not exceed $10^{-6}$. One can safely take $\varepsilon_1 = \varepsilon_2 = 10^{-3}$, which means that the system is certainly in equilibrium after a micro-second.

As we have already discussed in Section 1, this mathematical conclusion is in a sharp contradiction with the empirical fact that there are so many nonequilibrium states which lasts for quite a long time$^{18}$. The only reasonable resolution$^{19}$ seems to be that realistic

$^{18}$We also note that the relaxation time should grow with the size of the system, while the Boltzmann time $\tau_B$ is independent of the system size.

$^{19}$The states in the energy shell $\mathcal{H}$ are restricted in the sense that they are linear combinations of energy eigenstates corresponding to a narrow range of energy. We nevertheless expect that $\mathcal{H}$ is large enough to contain many states which are sufficiently far from nonequilibrium.
nonequilibrium subspaces form exceptions to the bound of the theorem, or, in other words, moderately slow decay observed in reality is not a typical property (if we assume random $H_{\text{neq}}$). See Section 1 for a discussion about the implication of this finding to the method of appeal to typicality.

The atypicality may not be too surprising, especially after knowing about it. Given the energy shell $H$, the nonequilibrium subspace $H_{\text{neq}}$, in reality, is determined not in a random manner, but through the values of macroscopic quantities that we use to characterize the system. Recall that many of the standard macroscopic quantities are expressed as a sum (or an integral) of locally conserved observables, and the Hamiltonian of a realistic system consists of more or less short-range interactions. This means that the corresponding subspace $H_{\text{neq}}$ and the projection operator $\hat{P}_{\text{neq}}$ should be special. It is likely, for example, that the commutator $[\hat{H}, \hat{P}_{\text{neq}}]$ is smaller for realistic subspaces compared with randomly chosen ones.

In order to fully understand the problem of the approach to equilibrium in macroscopic quantum systems, it may be essential to characterize realistic nonequilibrium subspaces, and to investigate the accompanying time scale.

Let us here give a crude picture based on the escape from a single state, which may be useful in understanding the nature of realistic nonequilibrium subspaces. Take an arbitrary state $\xi \in H$ and expand it as $\xi = \sum_{\alpha=1}^{D} \xi_{\alpha} \psi_{\alpha}$. Assume that the coefficient $\xi_{\alpha}$ is negligible (in a certain rough sense) unless $\alpha$ is such that $E_{\alpha} \in [\tilde{E}, \tilde{E} + \Delta E] \subset [U - \Delta U, U]$ for some energy $\tilde{E}$ and energy width $\Delta E$. We then take an initial state $\varphi(0) \in H$ which is close to $\xi$, and examine how quickly the state escapes from the vicinity of $\xi$. One readily finds that the overlap

$$\langle \varphi(t), \hat{p}\xi \varphi(t) \rangle = |\langle \xi, \varphi(t) \rangle|^{2} = \sum_{\alpha,\beta=1}^{D} (\xi_{\alpha})^{*} \xi_{\beta} c_{\alpha}(c_{\beta})^{*} e^{-i(E_{\alpha} - E_{\beta})t/\hbar}, \quad (2.18)$$

where we expanded $\varphi(0)$ as in (3.1), changes (and hence decays) in the time scale of order $\tau_{\text{esc}} := \hbar/\Delta E$. This property is well-known as the “uncertainty relation between time and energy”.

This observation suggests that a subspace $H_{\text{neq}}$ may also be characterized by certain energy scale $\Delta E$, which is similarly related to the associated relaxation time. This picture is true, at least for some examples, as we shall see now.

In the present setting of completely random $H_{\text{neq}}$, we see that each $\xi^{(j)}$ (for $j = 1, \ldots, d$) is characterized by the width (in the above sense) $\Delta E \approx k_{B}T$. This is because, in a macroscopic system, most of the energy eigenvalues $E$ such that $U - \Delta U \leq E \leq U$ are found in the smaller range with $U - \text{const} k_{B}T \leq E \leq U$, where the constant is of $O(V^{0})$. From this the conclusion that the escape time coincides with the Boltzmann time does indeed follow.

---

20In systems with short-range interactions, the relaxation time must grow with the system size because information propagates only with a finite speed. In fact it is very likely that, in a suitable class of systems, one can use the Lieb-Robinson bound [23] to prove lower bounds for the relaxation time which grows with the system size.

21Throughout the present paper we denote by $z^{*}$ the complex conjugate of $z$. 

10
Two examples of $H_{\text{neq}}$ in our previous work [18] are also consistent with the picture of escape time. In Theorem 1, where one finds extremely slow decay, we have $\Delta E = \Delta U/d$, which means $\tau_{\text{esc}} = h \, d/\Delta U$. In Theorem 2, where one finds quick decay, we have $\Delta E \approx \Delta U$, which means $\tau_{\text{esc}} \approx h/\Delta U$.

Remark 3 at the end of section 2.2 also provides an example. Here $\Delta U$ plays the role of the width $\Delta E$, which corresponds to the escape time $\tau_{\text{esc}} = h/\Delta U$. This is consistent with the bound (2.14).

This observation suggests that a realistic nonequilibrium subspace $H_{\text{neq}}$, determined through macroscopic quantities that we use to characterize the system, is associated with a certain energy width $\Delta E$. It is possible that the escape time $\tau_{\text{esc}}$, which may take a reasonable value depending on the value of $\Delta E$, essentially determines the relaxation time.

Of course it is also likely that the above picture of the escape from a single state is too naive or has only limited applicability. In some systems it may happen that $\varphi(t)$ is “trapped” in the vicinity of $H_{\text{neq}}$ in a more intricate manner. In such a situation the relaxation time should also depend on the number of independent $\xi^{(j)}$’s that the state $\varphi(t)$ should go through.

It is certainly an interesting challenge to examine these pictures in interacting many-body quantum systems and prove meaningful theorems. For the moment we only have limited rigorous results in abstract and artificial settings. In particular Theorem 1 of [18] treats examples with unphysically long relaxation time, and Theorem 2.1 of the present paper shows that a typical $H_{\text{neq}}$ leads to unphysically short relaxation time. The reality should lie in between these two extreme theorems, remaining to be understood.

### 3 Preliminary considerations and the proof of Theorem 2.1

Here we make some preliminary considerations, and introduce important quantities including the two matrices $S$ and $Q$. We shall prove Theorem 2.1 by assuming Proposition 3.1 and using Proposition 3.2.

Let $\varphi(0) \in \mathcal{H}$ be an arbitrary normalized initial state. We expand $\varphi(0)$ in the energy eigenstates as

$$\varphi(0) = \sum_{\alpha=1}^{D} c_{\alpha} \psi_{\alpha}, \quad (3.1)$$

where the normalization implies $\sum_{\alpha=1}^{D} |c_{\alpha}|^2 = 1$.

By recalling the time-evolution (2.2), we write the time average of the expectation
value of $\hat{P}_{\text{rnd}}$ as
\[
\frac{1}{\tau} \int_0^\tau dt \langle \varphi(t), \hat{P}_{\text{rnd}} \varphi(t) \rangle = \langle \varphi(0), \left\{ \frac{1}{\tau} \int_0^\tau dt e^{iHt/\hbar} \hat{P}_{\text{rnd}} e^{-iHt/\hbar} \right\} \varphi(0) \rangle = \sum_{\alpha,\beta=1}^D (c_\alpha)^* Q_{\alpha \beta} c_\beta, \tag{3.2}
\]
and we introduced
\[
Q_{\alpha \beta} := \langle \psi_\alpha, \left\{ \frac{1}{\tau} \int_0^\tau dt e^{iHt/\hbar} \hat{P}_{\text{rnd}} e^{-iHt/\hbar} \right\} \psi_\beta \rangle. \tag{3.3}
\]
Let us write the “matrix element” of the projection $\hat{P}_{\text{rnd}}$ as
\[
P_{\alpha \beta} := \langle \psi_\alpha, \hat{P}_{\text{rnd}} \psi_\beta \rangle = \sum_{j=1}^D \xi_\alpha^{(j)}(\xi_\beta^{(j)})^*, \tag{3.4}
\]
where we used (2.9), and expanded the (random) states as $\xi^{(j)} = \sum_{\alpha=1}^D |\xi_\alpha^{(j)}|^2 = 1$. Then by using (2.1), we can rewrite (3.3) as
\[
Q_{\alpha \beta} = \frac{1}{\tau} \int_0^\tau dt e^{iE_\alpha t/\hbar} P_{\alpha \beta} e^{-iE_\beta t/\hbar} = P_{\alpha \beta} S_{\alpha \beta}, \tag{3.5}
\]
with
\[
S_{\alpha \beta} := \frac{1}{\tau} \int_0^\tau dt e^{i(E_\alpha - E_\beta) t/\hbar} = \begin{cases} 1, & \text{if } E_\alpha = E_\beta; \\ e^{i\tau(E_\alpha - E_\beta) / \hbar} - 1, & \text{if } E_\alpha \neq E_\beta. \end{cases} \tag{3.6}
\]
We then define $D \times D$ matrices by $P = (P_{\alpha \beta})_{\alpha,\beta \in \{1,\ldots,D\}}$, $S = (S_{\alpha \beta})_{\alpha,\beta \in \{1,\ldots,D\}}$, and $Q = (Q_{\alpha \beta})_{\alpha,\beta \in \{1,\ldots,D\}}$. The matrix $Q$ is the Hadamard product of $P$ and $S$.

Note that $S$ is positive semi-definite as, for any $(c_\alpha)_{\alpha \in \{1,\ldots,D\}}$, we have
\[
\sum_{\alpha,\beta=1}^D (c_\alpha)^* S_{\alpha \beta} c_\beta = \frac{1}{\tau} \int_0^\tau dt \left| \sum_{\alpha=1}^D c_\alpha e^{-iE_\alpha t/\hbar} \right|^2 \geq 0. \tag{3.7}
\]
We also note that $Q$ is hermitian since both $P$ and $S$ are hermitian.\(^{22}\)

By $\mu_{\text{max}}$ and $\lambda_{\text{max}}$ we denote the maximum eigenvalues of $S$ and $Q$, respectively. Note that (3.2) implies
\[
\frac{1}{\tau} \int_0^\tau dt \langle \varphi(t), \hat{P}_{\text{rnd}} \varphi(t) \rangle = \sum_{\alpha,\beta=1}^D (c_\alpha)^* Q_{\alpha \beta} c_\beta \leq \lambda_{\text{max}} \tag{3.8}
\]
\(^{22}\)In fact $Q$ is positive semi-definite by Schur’s theorem. See also the proof of Proposition 3.1, especially (4.6).
where we noted that \( \sum_{\alpha=1}^{d} |c_{\alpha}|^2 = 1 \). Since the left-hand side of (3.2) never exceeds 1, we find that \( \lambda_{\text{max}} \leq 1 \).

Remark: It is useful to note that, for each (fixed) random unitary transformation \( \hat{U} \), the maximum eigenvalue \( \lambda_{\text{max}} \) is nondecreasing in \( d \). To see this, we write the \( d \)-dependences of the matrices explicitly, and note that \( Q^{(d)}_{\alpha\beta} - Q^{(\hat{d})}_{\alpha\beta} = (P^{(d)}_{\alpha\beta} - P^{(\hat{d})}_{\alpha\beta})S_{\alpha\beta} \) for \( d' \geq d \). Since \( \hat{P}^{(d')\text{rand}}_{\alpha\beta} - \hat{P}^{(d)\text{rand}}_{\alpha\beta} = \sum_{j=d+1}^{d'} \hat{P}(\xi_{\alpha\beta}) \) is positive semi-definite (see (2.9)), Shur’s lemma implies that \( Q^{(d')} - Q^{(d)} \) is positive semi-definite.

Mathematically speaking our most important result is the following proposition which roughly says that one typically has \( \lambda_{\max} \lesssim \mu_{\text{max}}/D \) (provided that \( \mu_{\text{max}} \) is large enough). We shall here state the proposition as that for general positive semi-definite matrices since this mathematical result itself may be of some interest from the point of view of random matrices. The proposition is proved in section 4.1 by using Proposition 4.1.

**Proposition 3.1** Suppose that the dimensions \( D \) and \( d \), and an integer \( n \geq 2 \) satisfy \( n^4d \leq 2D \). Let \( A = (A_{\alpha\beta})_{\alpha,\beta \in \{1,\ldots,D\}} \) be a \( D \times D \) positive semi-definite matrix whose maximum eigenvalue is \( \mu_{\text{max}} \). We assume that there is a constant \( \bar{\mu} \) such that

\[
\mu_{\text{max}} \leq \bar{\mu} \quad \text{and} \quad 1 \geq \frac{\bar{\mu}}{DA} \geq \left( \frac{d}{D} \right)^{1/4},
\]

(3.9)

where \( \bar{A} := \max_{1 \leq \alpha \leq D} A_{\alpha\alpha} \). Define another \( D \times D \) matrix \( B = (B_{\alpha\beta})_{\alpha,\beta \in \{1,\ldots,D\}} \) by the Hadamard product

\[
B_{\alpha\beta} = A_{\alpha\beta}P_{\alpha\beta} \quad (\alpha, \beta \in \{1,\ldots,D\}),
\]

(3.10)

where \( P_{\alpha\beta} \) is the element of the projection operator onto the random \( d \)-dimensional subspace as in (2.9) and (3.4).

Then for any \( \varepsilon > 0 \), the maximum eigenvalue \( \lambda_{\text{max}} \) of the matrix \( B \) satisfies\(^{23}\)

\[
\mathbb{P} \left[ \lambda_{\text{max}} \geq (1 + \varepsilon) \frac{\bar{\mu}}{D} \right] \leq 2e^3dD^{1/4} \left( \frac{1}{1 + \varepsilon} \right)^n
\]

(3.11)

where the probability is with respect to the random choice of the \( d \)-dimensional subspace.

Remark: There is a similar result which holds for hermitian (and not necessarily positive-semidefinite) matrix \( A \). Decompose \( A \) into the positive and negative parts\(^{24}\) as \( A = A^{(+)} + A^{(-)} \). Then \( B \) is also decomposed as \( B = B^{(+)} + B^{(-)} \), where \( B^{(\pm)} \) denotes the Hadamard product of \( A^{(\pm)} \) and \( P \). Since

\[
\lambda_{\text{max}} \leq \left( \text{max eigenvalue of } B^{(+)} \right) + \left( \text{max eigenvalue of } B^{(-)} \right)
\]

\[
\leq \left( \text{max eigenvalue of } B^{(+)} \right),
\]

(3.12)

\(^{23}\)When we apply the proposition, we let \( n \) large to make the right-hand side of (3.11) small.

\(^{24}\)Let \( (u_{\alpha}^{(\ell)})_{\alpha \in \{1,\ldots,D\}} \) and \( \mu_{\ell} \geq 0 \ (\ell \in \{1,\ldots,D\}) \) be the eigenvectors and the corresponding eigenvalues of \( A \), respectively. We then define \( A^{(\pm)}_{\alpha\beta} := \sum_{\ell : \mu_{\ell} \geq 0} \mu_{\ell} u_{\alpha}^{(\ell)}(u_{\beta}^{(\ell)})^\ast \), and \( A^{(-)}_{\alpha\beta} := \sum_{\ell : \mu_{\ell} < 0} \mu_{\ell} u_{\alpha}^{(\ell)}(u_{\beta}^{(\ell)})^\ast \), where \( A^{(+)} \) is positive semi-definite, and \( A^{(-)} \) is negative definite.
we only need to bound the maximum eigenvalue of $B^{(+)}$. This can be done by using Proposition 3.1 for $A^{(+)}$ and $B^{(+)}$.

We shall apply Proposition 3.1 by setting $A = S$. This means that we need an upper bound $\bar{\mu}$ for the maximum eigenvalue $\mu_{\text{max}}$ of $S$. We make use of the following upper bound, which indeed is almost optimal\(^{25}\).

**Proposition 3.2** Assume (2.6) and (2.7) for the density of states $\rho(E)$. Then the maximum eigenvalue $\mu_{\text{max}}$ of the matrix $S$ satisfies

$$
\mu_{\text{max}} \leq \bar{\mu} := \frac{\tau_B}{\tau} D \frac{1 + D^{-\kappa/5}/2}{1 - D^{-\kappa/5}} \sim \frac{\tau_B}{\tau} D, \tag{3.13}
$$

for any $\tau$ such that $0 < \tau \leq D^{\kappa/5} \tau_B$.

The proposition will be proved at the end of the present section.

**Remark:** The proposition may have applications in various problems of quantum mechanical time evolution. For example the function $\phi(t) := D^{-1/2} \sum_{\alpha=1}^{D} e^{it E_{\alpha}/\hbar}$ plays a fundamental role in the work by Cramer [17]. We can bound the time average of $|\phi(t)|^2$ as

$$
\frac{1}{\tau} \int_{0}^{\tau} dt |\phi(t)|^2 = D^{-1} \sum_{\alpha, \beta=1}^{D} D^{-1/2} S_{\alpha\beta} D^{-1/2} \leq \frac{\mu_{\text{max}}}{D} \leq \frac{\bar{\mu}}{D}, \tag{3.14}
$$

which may be useful in extending the results\(^ {26}\) in [17].

We are now ready to verify that our main theorem follows from these propositions.

**Proof of Theorem 2.1, assuming Propositions 3.1 and 3.2:** We shall set $A = S$. We have already remarked that $S$ is positive semi-definite. Also $\bar{A} = 1$ because of the definition (3.6).

Let us examine whether the upper bound $\bar{\mu}$ given by (3.13) satisfies the conditions (3.9). Since $\tau/\tau_B \leq (D/d)^{1/4}$ by (2.11), we see $\bar{\mu}/D \geq (d/D)^{1/4}$. The bound $1 \leq \bar{\mu}/D$, on the other hand, is not necessarily satisfied. But this is not a problem; if $\bar{\mu}/D > 1$ the desired bound (2.10) is trivially satisfied because the left-hand side never exceeds 1. We can thus safely restrict ourselves to the range of $\tau$ in which $1 \geq \bar{\mu}/D$.

For given $\varepsilon > 0$, we let $n$ be the smallest integer such that $2e^3dD^{1/4}/(1 + \varepsilon)^n \leq d/D$. Then (3.11) along with (3.8) implies the desired (2.10) because $B$ corresponds to $Q$.

In (2.10), we have replaced $\bar{\mu}$ of (3.13) by its upper bound $(\tau_B/\tau)D(1 + 2D^{-\kappa/5})$, which is justified because $D$ is sufficiently large as is explained below.

Let us examine the ranges of the dimensions $D$ and $d$. Since $n \leq \{\log(2e^3D^{1/4})/\log(1 + \varepsilon)\} + 1$, the condition $n^4d \leq 2D$ is guaranteed if

\(^{25}\)By using the variational argument described in [19], one can prove a lower bound which has the same asymptotic behavior (as $D \uparrow \infty$) as the upper bound.

\(^{26}\)It is likely that, for the class of models (with $N$ sites) in section 3.2 of [17], the bound (2.7) for the density of states is valid with $\tilde{\beta} = \text{const} \times N$. 

14
\[
d\left[\left\{ \log(2e^3D^{5/4})/\log(1 + \varepsilon) \right\} + 1 \right]^4 \leq D. \quad \text{This is the precise statement of the condition that \( d \) is sufficiently small (compared with \( D \)). To ensure that there is a positive \( d \) which satisfies the inequality, \( D \) must be sufficiently large to satisfy \( \left\{ \log(2e^3D^{5/4})/\log(1 + \varepsilon) \right\} + 1 \leq D \). If one chooses \( \varepsilon = 0.01 \), it suffices to set, e.g., \( D = 10^{50} \) and \( d = 10^{30} \). We emphasize that \( 10^{50} \) is much smaller than its typical expected value, \( D \approx \exp(10^{20}) \).} \]

Let us end the section by proving the upper bound on the maximum eigenvalue.

**Proof of Proposition 3.2:** Let \( u > 0 \). We define \( S^{(u)}_{\alpha\beta} \) by replacing \( \tau \) in (3.6) by \( u \). We also define \( R^{(u)}_{\alpha\beta} := u e^{-iuE_{\alpha}t/(2h)} S^{(u)}_{\alpha\beta} e^{iuE_{\beta}t/(2h)} \).

Note that the matrices \( (S^{(u)}_{\alpha\beta})_{\alpha,\beta \in \{1, \ldots, D \}} \) and \( (e^{-iuE_{\alpha}t/(2h)} S^{(u)}_{\alpha\beta} e^{iuE_{\beta}t/(2h)})_{\alpha,\beta \in \{1, \ldots, D \}} \) have exactly the same eigenvalues since they are related with each other by a trivial unitary transformation\(^{27} \). Thus the maximum eigenvalue of the matrix \( (R^{(u)}_{\alpha\beta})_{\alpha,\beta \in \{1, \ldots, D \}} \) is equal to \( \tau \mu_{\text{max}} \).

From (3.6) we find

\[
R^{(u)}_{\alpha\beta} = \int_{-u/2}^{u/2} dt e^{i(E_{\alpha} - E_{\beta})t/h} = \begin{cases} u, & \text{if } E_{\alpha} = E_{\beta}; \\ \sin[(E_{\alpha} - E_{\beta})u/(2h)]/(E_{\alpha} - E_{\beta})/(2h), & \text{if } E_{\alpha} \neq E_{\beta}. \end{cases} \tag{3.16}
\]

which means that \( (R^{(u)}_{\alpha\beta})_{\alpha,\beta \in \{1, \ldots, D \}} \) is a real symmetric matrix. Thus the maximum eigenvalue can be written as

\[
\tau \mu_{\text{max}} = \sup_{x_1, \ldots, x_D \in \mathbb{R}} \sum_{\alpha,\beta = 1}^{D} x_{\alpha} R^{(u)}_{\alpha\beta} x_{\beta}. \tag{3.17}
\]

This variational problem is not yet easy to treat since \( R^{(u)}_{\alpha\beta} \) has an oscillating sign. We overcome this difficulty by performing an extra integration in time.

Fix arbitrary \( x_1, \ldots, x_D \in \mathbb{R} \) such that \( \sum_{\alpha = 1}^{D} (x_{\alpha})^2 = 1 \). From the integral representation in (3.16), we get

\[
\sum_{\alpha,\beta = 1}^{D} x_{\alpha} R^{(u)}_{\alpha\beta} x_{\beta} = \int_{-u/2}^{u/2} dt \sum_{\alpha = 1}^{D} e^{-iE_{\alpha}t/h} x_{\alpha}^2, \tag{3.18}
\]

which implies that the quantity on the left-hand side is nonnegative and increasing in

---

\(^{27}\) The latter is obtained by replacing the range of integration in (3.6) by \([-\tau/2, \tau/2]\).
\( u > 0 \). Thus, for any \( 0 < \tau < \tau_{\text{max}} \), we have

\[
\sum_{\alpha, \beta = 1}^{D} x_{\alpha} R_{\alpha \beta}^{(\tau)} x_{\beta} \leq \frac{1}{\tau_{\text{max}} - \tau} \int_{\tau}^{\tau_{\text{max}}} \, du \sum_{\alpha, \beta = 1}^{D} x_{\alpha} R_{\alpha \beta}^{(u)} x_{\beta}
\]

\[
\leq \frac{1}{\tau_{\text{max}} - \tau} \int_{0}^{\tau_{\text{max}}} \, du \sum_{\alpha, \beta = 1}^{D} x_{\alpha} R_{\alpha \beta}^{(u)} x_{\beta} = \sum_{\alpha, \beta = 1}^{D} x_{\alpha} I_{\alpha \beta} x_{\beta},
\]

\[ (3.19) \]

where

\[
I_{\alpha \beta} := \frac{1}{\tau_{\text{max}} - \tau} \int_{0}^{\tau_{\text{max}}} \, du R_{\alpha \beta}^{(u)} = \frac{(\tau_{\text{max}})^2}{2(\tau_{\text{max}} - \tau)} g\left(\frac{(E_{\alpha} - E_{\beta}) \tau_{\text{max}}}{4h}\right),
\]

\[ (3.20) \]

with \( g(x) := (\sin x/x)^2 \). Remarkably, \( I_{\alpha \beta} \) is nonnegative.

By noting that \( 2x_{\alpha} x_{\beta} \leq (x_{\alpha})^2 + (x_{\beta})^2 \) and \( I_{\alpha \beta} = I_{\beta \alpha} \geq 0 \), we find

\[
\sum_{\alpha, \beta = 1}^{D} x_{\alpha} I_{\alpha \beta} x_{\beta} \leq \frac{1}{2} \sum_{\alpha, \beta = 1}^{D} \{(x_{\alpha})^2 I_{\alpha \beta} + I_{\alpha \beta}(x_{\beta})^2\} = \sum_{\alpha, \beta = 1}^{D} I_{\alpha \beta}(x_{\beta})^2
\]

\[
\leq \left( \sup_{\beta \in \{1, \ldots, D\}} \sum_{\alpha = 1}^{D} I_{\alpha \beta}\right) \sum_{\beta = 1}^{D} (x_{\beta})^2 = \sup_{\beta} \sum_{\alpha = 1}^{D} I_{\alpha \beta}.
\]

\[ (3.21) \]

Recalling (3.17) and (3.19), we get our main bound

\[
\tau \mu_{\text{max}} \leq \sup_{\beta} \sum_{\alpha = 1}^{D} I_{\alpha \beta}.
\]

\[ (3.22) \]

By replacing the sum on the right-hand side of (3.22) by an integral according to (2.5), we have

\[
\tau \mu_{\text{max}} \leq \frac{(\tau_{\text{max}})^2}{2(\tau_{\text{max}} - \tau)} \sup_{\beta} \left\{ \int_{U+U-\eta}^{U+\eta} \, dE \rho(E) g\left(\frac{(E - E_{\beta}) \tau_{\text{max}}}{4h}\right) + D^{1 - \kappa} \tau_{\text{max}} \bar{g}\right\},
\]

where \( \bar{g} := \sup_{x} |g'(x)| \sim 0.5402 \). By using (2.7), the integral is bounded as

\[
\leq \frac{(\tau_{\text{max}})^2}{2(\tau_{\text{max}} - \tau)} \sup_{\beta} \left\{ D \beta \int_{U-\Delta U-\eta}^{U+\eta} \, dE \rho(E) g\left(\frac{(E - E_{\beta}) \tau_{\text{max}}}{4h}\right) + D^{1 - \kappa} \frac{\pi \tau_{\text{max}} \bar{g}}{2\tau_{B}}\right\},
\]

\[
\leq \frac{(\tau_{\text{max}})^2}{2(\tau_{\text{max}} - \tau)} \left\{ D \beta \int_{-\infty}^{\infty} \, dE \rho(E) g\left(\frac{E \tau_{\text{max}}}{4h}\right) + D^{1 - \kappa} \frac{\pi \tau_{\text{max}} \bar{g}}{2\tau_{B}}\right\},
\]

where we also used the definition (2.8) of \( \tau_{B} \) to rewrite the error term. Recalling that \( \int_{-\infty}^{\infty} dx g(x) = \pi \), the integration can be evaluated to give

\[
\leq \frac{\tau_{\text{max}}}{\tau_{\text{max}} - \tau} D \tau_{B} \left( 1 + \frac{\pi \bar{g}}{4} \left(\frac{\tau_{\text{max}}}{\tau_{B}}\right)^2 D^{-\kappa}\right).
\]

\[ (3.23) \]

We finally choose \( \tau_{\text{max}} = D^{2\kappa/5} \tau_{B} \), and use the upper bound \( \tau \leq D^{\kappa/5} \tau_{B} \) to get

\[
\mu_{\text{max}} \leq \frac{1}{\tau} \frac{1}{1 - D^{-\kappa/5}} D \tau_{B} \left( 1 + \frac{\pi \bar{g}}{4} D^{-\kappa/5}\right) \leq \frac{\tau_{B} D}{\tau} \frac{1 + D^{-\kappa/5}/2}{1 - D^{-\kappa/5}},
\]

\[ (3.24) \]

which is the desired upper bound.
4 Main proposition and its proof

In the present section, which is the mathematical core of the present work, we state and prove Proposition 4.1 about general matrices. Proposition 3.1 is proved rather easily from Proposition 4.1.

4.1 Proof of Proposition 3.1

Let us state our main proposition. It deals with a matrix $A$ (with complex elements) which is not necessarily positive semi-definite, but satisfies a special condition (4.1).

**Proposition 4.1** Suppose that the dimensions $D$ and $d$, an integer $n \geq 2$, and some $\delta > 0$ satisfy $n^4d \leq 2D$ and $n^{2+(4/\delta)}d \leq D$. Let $A = (A_{\alpha\beta})_{\alpha,\beta \in \{1, \ldots, D\}}$ be a $D \times D$ matrix which satisfies

$$|(A^m)_{\alpha\beta}| \leq \bar{\mu}^{m-1}, \quad (\alpha, \beta \in \{1, 2, \ldots, n\})$$

for any positive integer $m$ with an $m$-independent constant $\bar{\mu}$ such that $0 < \bar{\mu} \leq D$.

Define another $D \times D$ matrix $B = (B_{\alpha\beta})_{\alpha,\beta \in \{1, \ldots, D\}}$ by the Hadamard product

$$B_{\alpha\beta} = A_{\alpha\beta}P_{\alpha\beta},$$

(4.2)

where $P_{\alpha\beta}$ is the element of the random projection operator onto a $d$-dimensional subspace as in (2.9) and (3.4). Then we have

$$28\bar{\mu}D[n - 1 + (e - 1) \left\{\bar{\mu} D \lor \left(\frac{d}{D}^{1/(2+\delta)}\right)^n\right\}] ,$$

(4.3)

where the expectation is with respect to the random choice of the $d$-dimensional subspace.

Proof of Proposition 3.1, assuming Proposition 4.1: We will prove the proposition assuming $\bar{A} = 1$. The case with $\bar{A} \neq 1$ can be reduced to this case by considering matrices $\tilde{A}$ and $\tilde{B}$, whose elements are defined as $\tilde{A}_{\alpha\beta} = A_{\alpha\beta}/\bar{A}$ and $\tilde{B}_{\alpha\beta} = B_{\alpha\beta}/\bar{A}$, respectively.

We begin by checking various conditions in Proposition 4.1. The condition $n^4d \leq 2D$ in Proposition 4.1 is also assumed in Proposition 3.1. We set $\delta = 2$. Then the condition $n^{2+(4/\delta)}d \leq D$ is satisfied since we have $n^4d \leq 2D$.

We then verify the condition (4.1). Recall that now $A$ is assumed to be positive semi-definite. Let $(u^{(\ell)}_\alpha)_{\alpha \in \{1, \ldots, D\}}$ and $\mu_\ell \geq 0$ ($\ell \in \{1, \ldots, D\}$) be the eigenvectors and the corresponding eigenvalues of $A$, respectively. We can write $A_{\alpha\beta} = \sum_{\ell=1}^{D} \mu_\ell u^{(\ell)}_\alpha (u^{(\ell)}_\beta)^*$. Then we note for $m \geq 1$ that

$$\left|(A^m)_{\alpha\beta}\right| = \sum_{\ell=1}^{D} (\mu_\ell)^m u^{(\ell)}_\alpha (u^{(\ell)}_\beta)^* \leq \sum_{\ell=1}^{D} (\mu_\ell)^m \frac{1}{2} \left\{|u^{(\ell)}_\alpha|^2 + |u^{(\ell)}_\beta|^2\right\}.$$  

(4.4)
We then observe that
\[ \sum_{\ell=1}^{D} (\mu_\ell)^m |u_\ell(t)|^2 \leq \bar{\mu}^{m-1} \sum_{\ell=1}^{D} \mu_\ell \| u_\ell(t) \|^2 = \bar{\mu}^{m-1} A_{aa} \leq \bar{\mu}^{m-1}, \tag{4.5} \]
where we used (3.9) and the fact that $\bar{A} = 1$. By substituting (4.5) into (4.4), we get the desired bound (4.1).

We next note that $B$ is positive semi-definite. This is guaranteed by Schur’s theorem, but let us give an elementary proof. Take an arbitrary $(x_\alpha)_{\alpha=1}^{D}$ and observe that
\[ \sum_{\alpha,\beta=1}^{D} (x_\alpha)^* B_{\alpha\beta} x_\beta = \sum_{\alpha,\beta=1}^{D} (x_\alpha)^* P_{\alpha\beta} A_{\alpha\beta} x_\beta = \sum_{\alpha,\beta=1}^{D} \sum_{j=1}^{D} (x_\alpha)^* \xi(j)_\alpha (\xi(j)_\beta)^* A_{\alpha\beta} x_\beta, \tag{4.6} \]
where we used (3.10), (3.4), and set $y_\alpha(j) = x_\alpha(\xi(j)_\alpha)^*$. We also used the fact that $A$ is positive semi-definite.

Now positive semi-definiteness of $B$ implies that
\[ \text{Tr}[B^n] = \sum_{\ell=1}^{D} (\lambda_\ell)^n \geq (\lambda_{\text{max}})^n, \tag{4.7} \]
where $\lambda_\ell \geq 0$ with $\ell \in \{1, \ldots, D\}$ are the eigenvalues of $B$.

Since we have (3.9), the main inequality (4.3) implies
\[ \mathbb{E}[(\lambda_{\text{max}})^n] \leq \mathbb{E}[\text{Tr}[B^n]] \leq 2e^3d \left\{ \left( \frac{\bar{\mu}}{D} \right)^{n-1} + (e-1) \left( \frac{\mu}{D} \right)^n \right\} \leq 2e^3d \left( \frac{\bar{\mu}}{D} \right)^{n-1}. \tag{4.8} \]

By using the Markov inequality, we find for any $\varepsilon > 0$ that
\[ \mathbb{P}\left[ \lambda_{\text{max}} \geq (1 + \varepsilon) \frac{\bar{\mu}}{D} \right] = \mathbb{P}\left[ (\lambda_{\text{max}})^n \geq \left\{ (1 + \varepsilon) \frac{\bar{\mu}}{D} \right\}^n \right] \leq \frac{\mathbb{E}[(\lambda_{\text{max}})^n]}{\left\{ (1 + \varepsilon) \frac{\bar{\mu}}{D} \right\}^n} \leq \frac{2e^3d \left( \frac{\bar{\mu}}{D} \right)^{n-1}}{\left\{ (1 + \varepsilon) \frac{\mu}{D} \right\}^n} \leq \frac{2e^3d}{(1 + \varepsilon)^n} \frac{D}{\mu (1 + \varepsilon)^n D^{1/4}} \leq \frac{2e^3d}{(1 + \varepsilon)^n (1 + \varepsilon)^{1/4}}, \tag{4.9} \]
where we used (3.9) and $d \geq 1$ to get the final bound.

### 4.2 Proof of Proposition 4.1

Now we shall prove Proposition 4.1. The exact expression (4.21) of Collins for integrals over the Haar measure of the unitary group plays a fundamental role in the proof. We make use of some properties of the symmetric group, which are summarized in the Appendix A.
4.2.1 Integration of \( d \)-dimensional random subspaces

We shall examine the expectation value \( \mathbb{E}[\text{Tr}[\mathcal{B}^n]] \), and rewrite it into a form suitable for further evaluation. From (4.2), we have

\[
\mathbb{E}[\text{Tr}[\mathcal{B}^n]] = \mathbb{E} \left[ \sum_{\alpha_1, \ldots, \alpha_n = 1}^D B_{\alpha_1 \alpha_2} B_{\alpha_2 \alpha_3} \cdots B_{\alpha_{n-1} \alpha_n} \right]
\]

\[
= \sum_{\alpha_1, \ldots, \alpha_n = 1}^D A_{\alpha_1 \alpha_2} A_{\alpha_2 \alpha_3} \cdots A_{\alpha_{n-1} \alpha_n} \mathbb{E}[P_{\alpha_1 \alpha_2} P_{\alpha_2 \alpha_3} \cdots P_{\alpha_{n-1} \alpha_n}].
\]

By writing the projection matrix in terms of the unit vectors as in (3.4), we can write the expectation value in the sum as

\[
\mathbb{E}[P_{\alpha_1 \alpha_2} P_{\alpha_2 \alpha_3} \cdots P_{\alpha_{n-1} \alpha_n}]
\]

\[
= \sum_{j_1, \ldots, j_n = 1}^d \mathbb{E} \left[ \xi_{\alpha_1}^{(j_1)} (\xi_{j_2}^{(j_2)})^* \xi_{\alpha_2}^{(j_2)} (\xi_{j_3}^{(j_3)})^* \cdots \xi_{\alpha_{n-1}}^{(j_{n-1})} (\xi_{j_n}^{(j_n)})^* \xi_{\alpha_n}^{(j_n)} (\xi_{\alpha_1}^{(j_1)})^* \right].
\]

Now we need to evaluate \( \mathbb{E} \left[ \xi_{\alpha_1}^{(j_1)} (\xi_{\alpha_2}^{(j_2)})^* \cdots \xi_{\alpha_n} (\xi_{\alpha_1}^{(j_n)})^* \right] \). Let us first be heuristic and present a rough estimate. Although we still know very little about this expectation value, it is apparent from the normalization and the symmetry that

\[
\mathbb{E} \left[ \xi_{\alpha_1}^{(j_1)} (\xi_{\alpha_2}^{(j_2)})^* \cdots \xi_{\alpha_n} (\xi_{\alpha_1}^{(j_n)})^* \right] \sim \frac{1}{D} \delta_{\alpha_1, \alpha_2}.
\]

It is expected that, in a crude approximation, one may treat \( (\xi_{\alpha_1}^{(j_1)})_{\alpha \in \{1, \ldots, D\}}, \ldots, (\xi_{\alpha_n}^{(j_n)})_{\alpha \in \{1, \ldots, D\}} \) as independent random vectors each of which distributed uniformly on the unit sphere in \( \mathbb{C}^D \). Then (4.12) is automatically satisfied. Of course the different vectors are not necessarily orthogonal with each other in this approximation, but they are almost orthogonal with probability close to one provided that \( d \ll D \). In fact it was shown by Weingarten in his pioneering work on the group integrals that this crude approximation gives the leading orders of the large-\( D \) limits of certain expectation values [24].

In this “first-order approximation” the relevant expectation becomes

\[
\mathbb{E} \left[ \xi_{\alpha_1}^{(j_1)} (\xi_{\alpha_2}^{(j_2)})^* \xi_{\alpha_2}^{(j_2)} (\xi_{\alpha_3}^{(j_3)})^* \cdots \xi_{\alpha_{n-1}}^{(j_{n-1})} (\xi_{\alpha_n}^{(j_n)})^* \xi_{\alpha_1}^{(j_n)} (\xi_{\alpha_1}^{(j_1)})^* \right] \sim \frac{1}{D^n} \prod_{s=1}^n \delta_{\alpha_s, \alpha_{s+1}}.
\]

Here (and in what follows) we identify \( \alpha_{n+1} \) with \( \alpha_1 \). Substituted into (4.11), this approximation yields

\[
\mathbb{E}[P_{\alpha_1 \alpha_2} P_{\alpha_2 \alpha_3} \cdots P_{\alpha_{n-1} \alpha_n}] \sim \left( \frac{d}{D} \right)^n \prod_{s=1}^n \delta_{\alpha_s, \alpha_{s+1}}.
\]

Note that the factor \( \prod_{s=1}^n \delta_{\alpha_s, \alpha_{s+1}} \) imposes the constraint that \( \alpha_1, \ldots, \alpha_n \) must be all identical. Thus, recalling (4.10), the present approximation gives

\[
\mathbb{E}[\text{Tr}[\mathcal{B}^n]] \sim \left( \frac{d}{D} \right)^n \sum_{\alpha=1}^D (A_{\alpha \alpha})^n.
\]
This estimate, with the assumption (4.1), implies
\[
\left| \mathbb{E} [\text{Tr}[\mathcal{B}^n]] \right| \lesssim \left( \frac{d}{D} \right)^n \sum_{\alpha=1}^D |A_{\alpha\alpha}|^{n} \leq D \left( \frac{d}{D} \right)^n,
\]
which, however, turns out not to be the major contribution to $\mathbb{E}[\text{Tr}[\mathcal{B}^n]]$. This is most easily seen by noticing that we have $A_{\alpha\alpha} = S_{\alpha\alpha} = 1$ in our original problem. Then the right-hand side of (4.15) is simply $D (d/D)^n$, which is independent of $\tau$. Although it is true that the approximations (4.13) or (4.14) gives the main term of the expectation value, the coupling with $A_{\alpha\beta}$ in (4.10) suppresses its contribution.

To find another contribution to $\mathbb{E}[\text{Tr}[\mathcal{B}^n]]$, we set $j_1 = \cdots = j_n = j$ in the expectation value $\mathbb{E} \left[ \xi_{(j)}^{(\alpha_1)} (\xi_{(j)}^{(\alpha_2)})^* \cdots (\xi_{(j)}^{(\alpha_n)})^* \right]$. We then find
\[
\mathbb{E} \left[ \xi_{(j)}^{(\alpha_1)} (\xi_{(j)}^{(\alpha_2)})^* \cdots (\xi_{(j)}^{(\alpha_n)})^* \right] = \mathbb{E} \left[ |\xi_{(j)}^{(\alpha_1)}|^2 |\xi_{(j)}^{(\alpha_2)}|^2 \cdots |\xi_{(j)}^{(\alpha_n)}|^2 \right] \sim \frac{1}{D^n},
\]
where we assumed for simplicity that all $\alpha_1, \ldots, \alpha_n$ are distinct, and used the fact that for any $j$ the coefficients $\xi_{(j)}^{(\alpha)}$ (with $\alpha = 1, \ldots, D$) of the random vector $\xi^{(j)}$ can be treated as independent random variables. Assuming that (4.13) and (4.17) give the dominant contributions, we find from (4.11) that
\[
\mathbb{E} \left[ P_{\alpha_1 \alpha_2} P_{\alpha_2 \alpha_3} \cdots P_{\alpha_n \alpha_1} \right] \sim \left( \frac{d}{D} \right)^n \prod_{s=1}^n \delta_{\alpha_s, \alpha_{s+1}} + \frac{d}{D^n}.
\]
Note that the first term in the right-hand side is larger but has the constraint on the $\alpha$’s while the second term is smaller but is (almost) free from constraint. Going back to (4.10), the second term yields a new contribution
\[
\sum_{\alpha_1, \ldots, \alpha_n=1}^D A_{\alpha_1 \alpha_2} A_{\alpha_2 \alpha_3} \cdots A_{\alpha_n \alpha_1} \frac{d}{D^n} = \text{Tr}[\mathcal{A}^n] \frac{d}{D^n},
\]
to $\mathbb{E}[\text{Tr}[\mathcal{B}^n]]$. Since $|\text{Tr}[\mathcal{A}^n]| \leq D \bar{\mu}^{n-1}$ by (4.1), we find
\[
\left| \mathbb{E}[\text{Tr}[\mathcal{B}^n]] \right| \lesssim D \left( \frac{d}{D} \right)^n + d \left( \frac{\bar{\mu}}{D} \right)^{n-1},
\]
where we again included the contribution (4.16). This is basically the desired bound (4.3), which is the main conclusion of Proposition 4.1. In our application, where $\bar{\mu} / D \sim \tau_B / \tau$, the second term in the right-hand side of (4.20) becomes the main contribution\textsuperscript{29} to $\mathbb{E}[\text{Tr}[\mathcal{B}^n]]$.

\textsuperscript{29}The first term becomes dominant when $\tau$ is extremely large.
4.2.2 Precise integration formula

It is a nontrivial task to make the above heuristic estimate into a rigorous one. In particular we have to treat the expectation value of $\xi$'s accurately, beyond the first order approximation (4.13). Fortunately we can make use of the recent development due to Collins and others on the integration with respect to the Haar measure on the unitary group \[21, 25\].

We shall summarize the results which are relevant to us. Let $d\mu_H(U)$ denote the Haar measure of the $D$-dimension unitary group $U(D)$, whose elements are matrices $U = (U_{\alpha\beta})_{\alpha,\beta \in \{1, \ldots, D\}}$. Then the integral of the matrix elements is given by Collins’ formula
\[
\int d\mu_H(U) \left( U_{\alpha'_1\beta'_1} U_{\alpha'_2\beta'_2} \cdots U_{\alpha'_n\beta'_n} \right)^* U_{\alpha_1\beta_1} U_{\alpha_2\beta_2} \cdots U_{\alpha_n\beta_n}
\]
where $S_n$ is the order-$n$ symmetric group, i.e., the set of all permutations of $\{1, 2, \ldots, n\}$. See Theorem 2.2 of [21] and Corollary 2.4 of [25]. Note that here (and in the following) $(U_{\alpha\beta})^*$ means the complex conjugate of the complex number $U_{\alpha\beta}$, not the hermitian conjugate.

The Weingarten-Collins function $Wg(\sigma)$ is a real valued function of $\sigma$, whose definition can be found in [21, 25]. Its leading behavior for large $D$ is given by $|Wg(\sigma)| \approx 1/D^{|\sigma|}$, where $|\sigma|$ denotes (throughout the present paper) the minimum number of transpositions necessary to express the permutation $\sigma$ as their products. See Appendix A.

We need an upper bound on $|Wg(\sigma)|$ for our proof. We shall make use of the following, which behaves more or less similar to the above mentioned leading behavior.

**Lemma 4.2** Let $n$ and $D$ satisfy $2n^2 \leq D$. Then for any $\sigma \in S_n$, we have
\[
|Wg(\sigma)| \leq 2e \frac{n^2|\sigma|}{D^{n+|\sigma|}} = 2e \frac{n^2}{D^n \binom{n+|\sigma|}{D}}.
\]

**Proof:** In the proof of Theorem 4 of [26], it is shown that
\[
|Wg(\sigma)| \leq \frac{n^2|\sigma|}{D^{n+|\sigma|}} \sum_{k=0}^{\infty} \left( \frac{n^2}{D} \right)^k.
\]
We get (4.22) by evaluating the summation. $\blacksquare$

We note that the condition $2n^2 \leq D$ for Lemma 4.2 is always satisfied under the conditions of Proposition 4.1. To see this note that $d \geq 1$ implies $n^2 \leq 2D$, which, along with $4 \leq n^2$, yields $2n^2 \leq D$.

Recall that our basis $\{\xi^{(j)}\}_{j=1,\ldots,d}$ is constructed from a random unitary transformation by $\xi^{(j)} = \tilde{U}\psi_j$. If we define a unitary matrix $U = (U_{\alpha\beta})_{\alpha,\beta \in \{1, \ldots, D\}}$ by
\( U_{\alpha \beta} := \langle \psi_\alpha, \hat{U} \psi_\beta \rangle \), we have \( U_{\alpha j} = \xi_\alpha^{(j)} \) where (as before) \( \xi_\alpha^{(j)} \) is the coefficient in the expansion \( \xi_\alpha = \sum_{\alpha=1}^D \xi_\alpha^{(j)} \psi_\alpha \). Then the expectation value in the summation in (4.11) is written as

\[
E[\xi_{\alpha_1} (\xi_{\alpha_2}^{(j_1)})^* \xi_{\alpha_2}^{(j_2)} (\xi_{\alpha_3}^{(j_2)})^* \ldots \xi_{\alpha_n}^{(j_n)} (\xi_{\alpha_1}^{(j_1)})^*] = \int d\mu_{\mathcal{H}}(U) \left(U_{\alpha_2 j_1} U_{\alpha_3 j_2} \ldots U_{\alpha_{n+1} j_n} \right)^* U_{\alpha_1 j_1} U_{\alpha_2 j_2} \ldots U_{\alpha_n j_n}.
\]

(4.24)

The right-hand side is a special case of (4.21), where we have \( \alpha' = \alpha_{k+1} \) and \( \beta' = j_k \). We thus find

\[
E[\xi_{\alpha_1}^{(j_1)} (\xi_{\alpha_2}^{(j_2)})^* \ldots \xi_{\alpha_n}^{(j_n)} (\xi_{\alpha_1}^{(j_1)})^*] = \sum_{\sigma, \tau \in \mathcal{S}_n} \sum_{\sigma, \tau \in \mathcal{S}_n} I[\forall k, \alpha_k = \alpha_{(k+1)} \text{ and } j_k = j_{(k+1)}] Wg(\tau \rho \sigma_1).
\]

(4.25)

We wish to rewrite the constraint \( \alpha_k = \alpha_{(k+1)} \) for any \( k \in \{1, \ldots, n\} \) (where we always identify \( n + 1 \) with 1) in a more convenient form. Note that the condition is equivalent to \( \alpha_{(k+1)} = \alpha_{k+1} \) for any \( k' \), and hence to \( \alpha_{(k+1)} = \alpha_{k+1} \) for any \( k \), where \( \sigma_1 \) is the shift defined by \( \sigma_1(\ell) = \ell + 1 \). Thus by defining \( \rho = \sigma_1^{-1} \), the condition can be rewritten as \( \alpha_k = \alpha_{(k)} \) for any \( k \). We can thus rewrite (4.25) as

\[
E[\xi_{\alpha_1}^{(j_1)} (\xi_{\alpha_2}^{(j_2)})^* \ldots \xi_{\alpha_n}^{(j_n)} (\xi_{\alpha_1}^{(j_1)})^*] = \sum_{\rho, \tau \in \mathcal{S}_n} \sum_{\rho, \tau \in \mathcal{S}_n} I[\forall k, \alpha_k = \alpha_{(k)} \text{ and } j_k = j_{(k)}] Wg(\tau \rho \sigma_1),
\]

where we noted that \( \sigma_1^{-1} = \rho \sigma_1 \).

Substituting this back to (4.10) and (4.11), we find that the quantity to be evaluated is rewritten and bounded as

\[
\left| E[\text{Tr}[B^n]] \right| = \left| \sum_{\alpha_1, \ldots, \alpha_n=1}^D \sum_{j_1, \ldots, j_n=1}^D \sum_{\rho, \tau \in \mathcal{S}_n} A_{\alpha_1 \alpha_2} A_{\alpha_2 \alpha_3} \ldots A_{\alpha_n \alpha_1} \times I[\forall k, \alpha_k = \alpha_{(k)} \text{ and } j_k = j_{(k)}] Wg(\tau \rho \sigma_1) \right|
\]

\[
= \left| \sum_{\rho \in \mathcal{S}_n} \left\{ \sum_{\alpha_1, \ldots, \alpha_n=1}^D A_{\alpha_1 \alpha_2} A_{\alpha_2 \alpha_3} \ldots A_{\alpha_n \alpha_1} I[\forall k, \alpha_k = \alpha_{(k)}] \right\} \right|
\]

\[
\times \left| \sum_{\tau \in \mathcal{S}_n} Wg(\tau \rho \sigma_1) \sum_{j_1, \ldots, j_n=1}^D I[\forall k, j_k = j_{(k)}] \right|
\]

\[
\leq \sum_{\rho \in \mathcal{S}_n} |S_1(\rho)| |S_2(\rho)|,
\]

(4.27)

where we introduced two summations

\[
S_1(\rho) := \sum_{\alpha_1, \ldots, \alpha_n=1}^D A_{\alpha_1 \alpha_2} A_{\alpha_2 \alpha_3} \ldots A_{\alpha_n \alpha_1} I[\forall k, \alpha_k = \alpha_{(k)}],
\]

(4.28)
and

\[ S_2(\rho) := \sum_{\tau \in \mathfrak{S}_n} Wg(\tau \rho \sigma_1) \sum_{j_1, \ldots, j_n=1}^d I[\forall k, j_k = j_{\tau(k)}]. \quad (4.29) \]

Now we shall separately bound \( |S_1(\rho)| \) and \( |S_2(\rho)| \).

### 4.2.3 Evaluation of \( |S_1(\rho)| \)

For any permutation \( \sigma \in \mathfrak{S}_n \), let \( i_\ell(\sigma) \) denote the number of distinct cycles of length \( \ell \) in \( \sigma \). In particular \( i_1(\sigma) \) denotes the number of \( k \in \{1, \ldots, n\} \) such that \( \sigma(k) = k \). We also denote the total number of cycles in \( \sigma \) as \( c(\sigma) := \sum_{\ell=1}^n i_\ell(\sigma) \). See Appendix A.

Then we have the following bound for \( |S_1(\rho)| \).

**Lemma 4.3** For any \( \rho \in \mathfrak{S}_n \), we have

\[ |S_1(\rho)| \leq \begin{cases} D \tilde{\mu}^{n-1}, & \text{if } \rho = \text{id}; \\ D^{c(\rho)} \left( \frac{\tilde{\mu}}{D} \right)^{i_1(\rho)}, & \text{if } \rho \neq \text{id}. \end{cases} \quad (4.30) \]

**Proof:** As a warm up, we consider two extreme cases. First we set \( \rho = \text{id} \), and observe that the constraint “\( \alpha_k = \alpha_{\rho(k)} \) for any \( k \)” is satisfied for any choice of \( \alpha_1, \ldots, \alpha_n \). We then simply sum over \( \alpha_1, \ldots, \alpha_n \) in (4.28) to get

\[ S_1(\text{id}) = \sum_{\alpha_1, \ldots, \alpha_n=1}^D A_{\alpha_1 \alpha_2} A_{\alpha_2 \alpha_3} \cdots A_{\alpha_n \alpha_1} = \text{Tr}[A^n]. \quad (4.31) \]

By using the assumption (4.1), we get

\[ |S_1(\text{id})| \leq \sum_{\alpha=1}^D |(A^n)_{\alpha \alpha}| \leq D \tilde{\mu}^{n-1}, \quad (4.32) \]

which proves (4.30) for \( \rho = \text{id} \). It turns out that this is indeed the main contribution to the summation in the right-hand side of (4.27).

The second extreme case is \( \rho = \sigma_1^{-1} \), which, in the original language in (4.25), corresponds to \( \sigma = \text{id} \). Here the constraint reads “\( \alpha_k = \alpha_{k-1} \) for all \( k \)”, which in fact means \( \alpha_1 = \alpha_2 = \cdots = \alpha_n \). We thus find from (4.28) that

\[ S_1(\sigma_1^{-1}) = \sum_{\alpha=1}^D A_{\alpha \alpha} A_{\alpha \alpha} \cdots A_{\alpha \alpha}, \quad (4.33) \]

which, with the assumption (4.1), means

\[ |S_1(\sigma_1^{-1})| \leq \sum_{\alpha=1}^D 1 = D. \quad (4.34) \]
Figure 1: A diagram which represents the sum (4.28) for \( \rho = (5, 23, 43)(19, 28)(15, 32) \). (a) Without the constraint imposed by \( I[\forall k, \alpha_k = \alpha_{\rho(k)}] \), we have a simple single loop with 48 points on it. (b) With the constraint, we glue several points together to form the diagram on the right. Glued vertices \( (5 = 23 = 43, 19 = 28, 15 = 32) \) are denoted by big dots.

The bound (4.30) is trivially satisfied because \( c(\sigma_1) = 1 \) and \( i_1(\sigma_1) = 0 \). We also note that this contribution corresponds to the crude (and indeed useless) estimate in (4.12)–(4.15).

To deal with a general permutation \( \rho \neq \text{id} \), it is crucial to decompose \( \rho \) into a product of disjoint cycles (see Appendix A). As an example let \( n = 48 \) and consider the permutation \( \rho = (5, 23, 43)(19, 28)(15, 32) \), where the three series of indices denote three cycles, and all the other indices are unchanged. In this case, the constraint “\( \alpha_k = \alpha_{\rho(k)} \) for any \( k \)” in (4.28) reads \( \alpha_5 = \alpha_{23} = \alpha_{43}, \alpha_{19} = \alpha_{28}, \text{ and } \alpha_{15} = \alpha_{32} \).

It is illuminating to represent the constraint diagrammatically as in Figure 1. We first represent the product \( A_{\alpha_1} A_{\alpha_2} A_{\alpha_3} \cdots A_{\alpha_{48}} \) as a simple loop with 48 points, where the points represent the indices \( i = 1, \ldots, 48 \), and the edges represent the elements \( A_{\alpha_i \alpha_{i+1}} \) with \( i = 1, \ldots, 48 \) (where we identify 49 with 1) as in Figure 1(a). To take into account the constraint, we identify (or glue together) those points corresponding to \( \alpha \)'s which are set equal. Figure 1(b) shows the resulting diagram. A vertex with degree \( \geq 4 \) is called a *glued vertex*, and is denoted by a big dot. Those points which are not identified with others are called *single points*.

Let us examine the summation (4.28). We first sum over all \( \alpha \)'s corresponding to single points. Note that single points are located on lines whose end-points are glued vertices (or a glued vertex). There are seven such lines in Figure 1(b). As an example, consider the line which contains 5, 6, 7, \ldots, 14, and 15. Then the summation is readily

\[ \sum_{\alpha} A_{\alpha_1} A_{\alpha_2} A_{\alpha_3} \cdots A_{\alpha_{48}} \]
evaluated as
\[ \sum_{\alpha_6, \alpha_7, \ldots, \alpha_{14}=1}^{D} A_{\alpha_5 \alpha_6} A_{\alpha_6 \alpha_7} \cdots A_{\alpha_{14} \alpha_{15}} = (A^{(0)}_{\alpha_6 \alpha_{15}}) \tag{4.35} \]
which, again with the assumption (4.1), implies the upper bound
\[ \left| \sum_{\alpha_6, \alpha_7, \ldots, \alpha_{14}=1}^{D} A_{\alpha_5 \alpha_6} A_{\alpha_6 \alpha_7} \cdots A_{\alpha_{14} \alpha_{15}} \right| \leq (\bar{\mu})^9. \tag{4.36} \]

Note here that 9 is precisely the number of single points on the line. This is true in general since the sum corresponding to a line with \( \ell \) edges yields \( (A^{(\ell)}_{\alpha \alpha'}) \), which is bounded as \( |(A^{(\ell)}_{\alpha \alpha'})| \leq \bar{\mu}^{\ell-1} \) with \( \ell - 1 \) being the number of single points on the line.

Recall that the number of single points on the whole diagram is equal to the number of fixed points of \( \rho \), which is \( i_1(\rho) \). We thus find that the summation over all \( \alpha \)'s corresponding to single points gives
\[ \left| \left( \prod_{i:\text{single point}} \sum_{\alpha_i=1}^{D} A_{\alpha_1 \alpha_2} A_{\alpha_2 \alpha_3} \cdots A_{\alpha_n \alpha_1} \right) \right| \leq \bar{\mu}^{i_1(\rho)}. \tag{4.37} \]

It remains to sum the upper bound \( \bar{\mu}^{i_1(\rho)} \) over all \( \alpha \)'s on glued vertices. We note that the number of the glued vertices is equal to the number of cycles with length greater than one, and is given by \( c(\rho) - i_1(\rho) \). We thus find
\[ |S_1(\rho)| \leq D^{c(\rho) - i_1(\rho)} \bar{\mu}^{i_1(\rho)} = D^{c(\rho)} \left( \frac{\bar{\mu}}{D} \right)^{i_1(\rho)}, \tag{4.38} \]
which proves (4.30) for \( \rho \neq \text{id} \).

4.2.4 Evaluation of \( |S_2(\rho)| \)

**Lemma 4.4** Under the conditions \( n^4d \leq 2D \) and \( n \geq 2 \), we have
\[ |S_2(\rho)| \leq 2e^{2D^{-n}d^{c(\rho)\alpha_1}}. \tag{4.39} \]

**Proof:** For fixed \( \tau \), the sum over \( j_1, \ldots, j_n \) is evaluated to be
\[ \sum_{j_1, \ldots, j_n=1}^{d} I[\forall k, j_k = j_{\tau(k)}] = d^{c(\tau)}. \tag{4.40} \]
To see this we decompose \( \tau \) into a product of disjoint cycles, and note that \( j_k \) should be equal on each cycle in order to satisfy the constraint that \( j_k = j_{\tau(k)} \) for any \( k \). Since the number of distinct cycles in \( \tau \) is \( c(\tau) \), we get (4.40).
By recalling the definition (4.29) of $S_2(\rho)$, and using the upper bound (4.22) for the Weingarten-Collins function, we get

$$|S_2(\rho)| \leq 2eD^{-n} \sum_{\tau \in \mathfrak{S}_n} \left( \frac{n^2}{D} \right)^{|\tau \rho \sigma_1|} d^c(\tau). \quad (4.41)$$

We define new permutation $\omega := \tau \rho \sigma_1$, and sum over $\omega$ instead of $\tau$ to find

$$|S_2(\rho)| \leq 2eD^{-n} \sum_{\omega \in \mathfrak{S}_n} \left( \frac{n^2}{D} \right)^{|\omega|} d^c(\omega^{-1} \rho^{-1}) \leq 2eD^{-n} d^c(\rho \sigma_1) \sum_{\omega \in \mathfrak{S}_n} \left( \frac{n^2}{D} \right)^{|\omega|}, \quad (4.42)$$

where we used

$$c(\omega^{-1} \rho^{-1}) \leq |\omega| + c(\sigma_1^{-1} \rho^{-1}) = |\omega| + c(\rho \sigma_1), \quad (4.43)$$

which is a consequence of (A.10).

To evaluate the sum over $\omega$, we let $a_{n,k}$ be the number of $\omega \in \mathfrak{S}_n$ with $|\omega| = k$, and use the bound (A.13) where $N = n(n-1)/2$ to get

$$\sum_{\omega \in \mathfrak{S}_n} \left( \frac{n^2}{D} \right)^{|\omega|} = \sum_{k=0}^{n-1} a_{n,k} \left( \frac{n^2}{D} \right)^k \leq \sum_{k=0}^{n-1} \binom{N}{k} \left( \frac{n^2}{D} \right)^k \leq \exp\left( \frac{n^2D}{D} \right) \leq e, \quad (4.44)$$

where we noted that the condition $n^4d \leq 2D$ implies $n^2dN \leq D$. Substituting this bound into (4.42), we get the desired (4.39).

4.2.5 The sum over $\rho$

We are ready to prove the desired bound (4.3) for $\mathbb{E}[\text{Tr}[B^n]]$. We recall from (4.27) that

$$\left| \mathbb{E}[\text{Tr}[B^n]] \right| \leq \sum_{\rho \in \mathfrak{S}_n} |S_1(\rho)| |S_2(\rho)|, \quad (4.45)$$

and use the bounds obtained for the right-hand side.

Proof of Proposition 4.1: Substituting the bounds (4.30) for $|S_1(\rho)|$ and (4.39) for $|S_2(\rho)|$ into (4.45), we find

$$\left| \mathbb{E}[\text{Tr}[B^n]] \right| \leq 2e^2d \left( \frac{\bar{\mu}}{D} \right)^{n-1} + 2e^2 \sum_{\rho \in \mathfrak{S}_n \atop (\rho \neq \text{id})} D^c(\rho)^{-n} \left( \frac{\bar{\mu}}{D} \right)^{i_1(\rho)} d^c(\rho \sigma_1), \quad (4.46)$$

26
where we noted that $c(\sigma_1) = 1$. By using (A.6), which is $c(\rho) + c(\rho \sigma_1) \leq n + 1$, (4.46) is bounded as

$$
\left| \mathbb{E} [\text{Tr} [B^\nu]] \right| \leq 2\epsilon^2 d \left( \frac{\mu}{D} \right)^{n-1} + 2\epsilon^2 \sum_{\rho \in \mathcal{S}_n \ (\rho \neq \text{id})} D^{c(\rho)} \left( \frac{\mu}{D} \right)^{i_1(\rho)} d^{n+1-c(\rho)} \]
$$

$$
= 2\epsilon^2 d \left[ \left( \frac{\mu}{D} \right)^{n-1} + \sum_{\rho \in \mathcal{S}_n \ (\rho \neq \text{id})} \left( \frac{\mu}{D} \right)^{i_1(\rho)} \left( \frac{d}{D} \right)^{n-c(\rho)} \right]. \quad (4.47)
$$

If we further use (A.2), which is $c(\rho) = n - |\rho|$, the upper bound becomes

$$
= 2\epsilon^2 d \left[ \left( \frac{\mu}{D} \right)^{n-1} + \sum_{\rho \in \mathcal{S}_n \ (\rho \neq \text{id})} \left( \frac{\mu}{D} \right)^{i_1(\rho)} \left( \frac{d}{D} \right)^{|\rho|} \right]. \quad (4.48)
$$

We shall bound the sum over $\rho$ in the right-hand side. In the following estimate, the inequality (A.3), which is

$$
2|\rho| + i_1(\rho) \geq n, \quad (4.49)
$$

plays an important role. To simplify notation let us write $\nu := \mu/D$ and $\zeta := d/D$, and note that both quantities are expected to be small. In particular the assumptions in the proposition imply that $\nu \leq 1$ and $N^{1+2/\delta} \zeta \leq 1$ (which is guaranteed by the assumption $n^{2+(4/\delta)} d \leq D$), where we again write $N = n(n - 1)/2$.

Suppose first that $\zeta \leq \nu^{2+\delta}$. We use the trivial identity $\zeta = \zeta^{2/(2+\delta)} \times \zeta^{\delta/(2+\delta)}$ together with (4.49) to get

$$
\nu^{i_1(\rho)} \zeta^{|\rho|} = \nu^{i_1(\rho)} \left( \zeta^{2/(2+\delta)} \right)^{|\rho|} \left( \zeta^{\delta/(2+\delta)} \right)^{|\rho|} \leq \nu^{i_1(\rho)} \nu^{2|\rho|} \left( \zeta^{\delta/(2+\delta)} \right)^{|\rho|} 
$$

$$
= \nu^{i_1(\rho)+2|\rho|} \left( \zeta^{\delta/(2+\delta)} \right)^{|\rho|} \leq \nu^n \left( \zeta^{\delta/(2+\delta)} \right)^{|\rho|}. \quad (4.50)
$$

We then use (A.13) to bound the number of $\rho$ with $|\rho| = k$ (note that $\rho \neq \text{id}$ means $k \geq 1$) to find

$$
\sum_{\rho \in \mathcal{S}_n \ (\rho \neq \text{id})} \nu^{i_1(\rho)} \zeta^{|\rho|} \leq \nu^n \sum_{\rho \in \mathcal{S}_n \ (\rho \neq \text{id})} \left( \zeta^{\delta/(2+\delta)} \right)^{|\rho|} \leq \nu^n \sum_{k=1}^{n-1} \binom{n}{k} \left( \zeta^{\delta/(2+\delta)} \right)^k \leq \nu^n \sum_{k=1}^{n-1} \frac{N^k}{k!} \left( \zeta^{\delta/(2+\delta)} \right)^k 
$$

$$
= \nu^n \sum_{k=1}^{n-1} \frac{1}{k!} \left( N \zeta^{\delta/(2+\delta)} \right)^k \leq \nu^n \left\{ \exp \left( N \zeta^{\delta/(2+\delta)} \right) - 1 \right\} \leq (e - 1) \nu^n, \quad (4.51)
$$

where we used $N \zeta^{\delta/(2+\delta)} \leq 1$ or, equivalently, $N^{1+2/\delta} \zeta \leq 1$.

Next suppose that $\zeta \geq \nu^{2+\delta}$. Here we simply bound $\nu$ as $\nu \leq \zeta^{1/(2+\delta)}$, and use (4.49) to get

$$
\nu^{i_1(\rho)} \zeta^{|\rho|} \leq \left( \zeta^{1/(2+\delta)} \right)^{i_1(\rho)} \zeta^{|\rho|} = \left( \zeta^{1/(2+\delta)} \right)^{i_1(\rho)+2|\rho|+\delta|\rho|} \leq \left( \zeta^{1/(2+\delta)} \right)^n \left( \zeta^{\delta/(2+\delta)} \right)^{|\rho|}. \quad (4.52)
$$
Since the sum of $(\zeta^{\delta/(2+\delta)})^{\nu |\rho|}$ over $\rho \in G_n \setminus \{\text{id}\}$ has been shown to be less than or equal to $e - 1$ in (4.51), we find
\[
\sum_{\rho \in G_n \setminus \{\text{id}\}} \nu^{i_1(\rho)} \zeta^{|\rho|} \leq (e - 1) \left( \zeta^{1/(2+\delta)} \right)^n.
\] (4.53)

Combining (4.51) and (4.53), we finally get
\[
\sum_{\rho \in G_n \setminus \{\text{id}\}} \nu^{i_1(\rho)} \zeta^{|\rho|} \leq (e - 1) \left( \nu \lor \zeta^{1/(2+\delta)} \right)^n = (e - 1) \left\{ \frac{\mu}{D} \lor \left( \frac{d}{D} \right)^{1/(2+\delta)} \right\}^n.
\] (4.54)

Going back to (4.47), we obtain
\[
\left| \mathbb{E} \left[ \text{Tr}[B^n] \right] \right| \leq 2e^2d \left[ \left( \frac{\mu}{D} \right)^{n-1} + (e - 1) \left\{ \frac{\mu}{D} \lor \left( \frac{d}{D} \right)^{1/(2+\delta)} \right\}^n \right],
\] (4.55)
which is the main inequality (4.3) in Proposition 4.1.

\section{A Some elementary facts about the symmetric group}

We shall here summarize some elementary facts about the symmetric group that we used in the proof. Although most (or all) of these facts may be well-known to experts, we include the proofs of some statements for completeness.

By $G_n$ we denote the symmetric group of order $n$, i.e., a group consisting of all permutations of $\{1, \ldots, n\}$.

Any $\sigma \in G_n$ can be written as a product of transpositions. By $|\sigma|$ we denote the minimum number of transpositions needed in such a representation.

A cycle (or a cyclic permutation) of length $\ell$ is a special permutation in which only $\ell$ indices $j_1, \ldots, j_\ell \in \{1, \ldots, n\}$ are changed in a cyclic manner, i.e., $j_k \to j_{k+1}$ (where we identify $j_{\ell+1}$ with $j_1$). It is abbreviated as $(j_1, \ldots, j_\ell)$.

Any $\sigma \in G_n$ can be decomposed into a product of disjoint cycles. The decomposition is unique up to the ordering of the cycles. We denote by $i_\ell(\sigma)$ the number of cycles of length $\ell$ in this decomposition. We define $i_1(\sigma)$ to be the number of indices $j$ such that $\sigma(j) = j$. Note the trivial identity $n = \sum_{\ell=1}^{n} \ell i_\ell(\sigma)$. We also denote by
\[
c(\sigma) = \sum_{\ell=1}^{n} i_\ell(\sigma)
\] (A.1)
the total number of cycles in $\sigma$.

Let $\ell \geq 2$ and $\tau$ be a cycle of length $\ell$. One finds by inspection that $|\tau| = \ell - 1$. This fact implies for general $\sigma \in G_n$ the well known identity
\[
|\sigma| + c(\sigma) = n.
\] (A.2)
Lemma A.1 For any $\sigma \in S_n$, one has
\[ 2|\sigma| + i_1(\sigma) \geq n. \tag{A.3} \]

Proof: Simply note that
\[
|\sigma| = n - c(\sigma) = \sum_{\ell=1}^{n} \ell i_{\ell}(\sigma) - \sum_{\ell=1}^{n} i_{\ell}(\sigma) = \sum_{\ell=2}^{n} (\ell - 1) i_{\ell}(\sigma) \\
\geq \sum_{\ell=2}^{n} \frac{\ell}{2} i_{\ell}(\sigma) = \frac{1}{2} \left\{ \left( \sum_{\ell=1}^{n} \ell i_{\ell}(\sigma) \right) - i_{1}(\sigma) \right\} = \frac{1}{2} \{n - i_{1}(\sigma)\}. \tag{A.4}
\]

Lemma A.2 For any permutations $\sigma$ and $\rho$, one has
\[ c(\sigma) + c(\rho) \leq n + c(\sigma \rho). \tag{A.5} \]

If $\sigma_1$ denotes the shift defined by $\sigma_1(k) = k + 1$ (where we identify $n + 1$ with 1), then (A.5) implies for any $\rho \in S_n$ that
\[ c(\rho) + c(\rho \sigma_1) = c(\rho \sigma_1) + c(\rho^{-1}) \leq n + c(\sigma_1) = n + 1. \tag{A.6} \]

Proof of Lemma A.2: By (A.2), we have
\[ c(\sigma) + c(\rho) = 2n - |\sigma| - |\rho|. \tag{A.7} \]

But we trivially have
\[ |\sigma \rho| \leq |\sigma| + |\rho|, \tag{A.8} \]

since we can construct $\sigma \rho$, by using transpositions used for $\sigma$ and $\rho$. Therefore,
\[ c(\sigma) + c(\rho) = 2n - |\sigma| - |\rho| \leq 2n - |\sigma \rho| = n + c(\sigma \rho), \tag{A.9} \]

where we again used (A.2).

Lemma A.3 For any $\omega, \sigma \in S_n$, one has
\[ c(\omega \sigma) \leq |\omega| + c(\sigma). \tag{A.10} \]

In particular, if $\tau$ is a transposition,
\[ c(\tau \sigma) \leq c(\sigma) + 1. \tag{A.11} \]
Proof: We shall prove (A.11). Then (A.10) follows by decomposing \( \omega \) into \(|\omega|\) transpositions and by using (A.11) repeatedly.

We decompose \( \sigma \) into disjoint cycles as \( \sigma = c_1c_2\ldots c_m \) where \( m = c(\sigma) \), and examine the decomposition of \( \tau\sigma \) into disjoint cycles. There are two cases. (i) Suppose that \( \tau \) interchanges two elements in a single cycle \( c_i \). Then one easily finds (by explicit construction) that \( c_i \) splits into two disjoint cycles by the action of \( \tau \). We thus have \( c(\tau\sigma) = c(\sigma) + 1 \). (ii) Suppose that \( \tau \) interchanges an element in \( c_i \) and an element in \( c_j \), where \( i \neq j \). Again one can easily check that the action of \( \tau \) merges \( c_i \) and \( c_j \) to form a bigger single cycle. We thus have \( c(\tau\sigma) = c(\sigma) - 1 \).

Lemma A.4 Let \( a_{n,k} \) be the number of \( \sigma \in \mathfrak{S}_n \) with \(|\sigma| = k\). Its generating function is exactly given by

\[
\sum_{k=0}^{n-1} a_{n,k} x^k = \prod_{j=1}^{n-1} (1 + jx). \tag{A.12}
\]

Moreover, \( a_{n,k} \) satisfies

\[
a_{n,k} \leq \binom{N}{k}, \tag{A.13}
\]

where \( N := n(n-1)/2 \).

Proof: We shall prove (A.12) by induction in \( n \). For \( n = 2 \), we easily see that \( a_{2,0} = a_{2,1} = 1 \), which proves (A.12). For \( n \geq 3 \), we assume the statement for \( \mathfrak{S}_{n-1} \), and prove the statement for \( \mathfrak{S}_n \). Decompose the permutation group as \( \mathfrak{S}_n = \mathfrak{S}_n^{(1)} \cup \mathfrak{S}_n^{(2)} \), where \( \mathfrak{S}_n^{(1)} = \{ \sigma \in \mathfrak{S}_n \mid \sigma(n) = n \} \) and \( \mathfrak{S}_n^{(2)} = \{ \sigma \in \mathfrak{S}_n \mid \sigma(n) \neq n \} \). Since \( \mathfrak{S}_n^{(1)} \) is essentially the same as \( \mathfrak{S}_{n-1} \), we see that the number of \( \sigma \in \mathfrak{S}_n^{(1)} \) with \(|\sigma| = k\) is equal to \( a_{n-1,k} \).

For \( \sigma \in \mathfrak{S}_n^{(2)} \), let \( i = \sigma(n) \). Note that \( \sigma \) must have a cycle which contains both \( n \) and \( i \). We simply eliminate \( n \) from this cycle to form a new shorter cycle. In this manner we obtain a new permutation \( \sigma' \in \mathfrak{S}_{n-1} \). Then we obviously have \(|\sigma'| = |\sigma| - 1\) since we need one less transpositions for the shortened cycle\(^{30}\). This means that the number of \( \sigma \in \mathfrak{S}_n^{(2)} \) with \(|\sigma| = k\) is given by \((n-1)a_{n-1,k-1}\), where the factor \( n - 1 \) comes from the choice of \( i \in \{1, \ldots, n-1\} \). By summing up the contributions from \( \mathfrak{S}_n^{(1)} \) and \( \mathfrak{S}_n^{(2)} \), we get the recursion relation

\[
a_{n,k} = a_{n-1,k} + (n-1)a_{n-1,k-1}. \tag{A.14}
\]

Summing this up and using the inductive assumption, we get

\[
\sum_{k=0}^{n-1} a_{n,k} x^k = \sum_{k=0}^{n-2} a_{n-1,k} x^k + (n-1)x \sum_{k=1}^{n-1} a_{n-1,k-1} x^{k-1} = \left\{ 1 + (n-1)x \right\} \sum_{k=0}^{n-2} a_{n-1,k} x^k = \prod_{j=1}^{n-1} (1 + jx). \tag{A.15}
\]

\(^{30}\)A more formal proof: Note that \( c(\sigma) = c(\sigma') \) by construction, and then from (A.2) that \(|\sigma'| = (n-1) - c(\sigma') = n - 1 - c(\sigma) = |\sigma| - 1\).
To prove (A.13), we note that the coefficient of $x^k$ ($k \leq n - 1$) of

$$\sum_{k=0}^{N} \binom{N}{k} x^k = (1 + x)^N = \prod_{j=1}^{n-1} (1 + x)^j$$

(A.16)

is not less than that of

$$\prod_{j=1}^{n-1} (1 + jx),$$

(A.17)

because $(1 + x)^j$ has more terms (with positive coefficients) than $(1 + jx)$.

\section*{B \ On the density of states}

Here we shall explain a way to explicitly construct the density of states. We also justify the formula (2.5), which allows one to convert a summation into an integral.

Suppose that the energy eigenvalues $E_1, \ldots, E_D \in [U - \Delta U, U]$ are given. We define a smooth function\footnote{Any normalized smooth function with a finite support centered at the origin can be used as $k(x)$. We here stick to this choice just for concreteness.}

$$k(x) := \begin{cases} 
N \exp\{- (1 - x^2)^{-1}\}, & \text{if } |x| < 1; \\
0, & \text{otherwise},
\end{cases}$$

(B.1)

where $N \sim 2.2523$ is a normalization factor introduced to realize $\int k(x) dx = 1$. For any $\eta > 0$, we define

$$\rho_\eta(E) := \sum_{\alpha=1}^{D} \frac{1}{\eta} k \left( \frac{E - E_\alpha}{\eta} \right).$$

(B.2)

Then we can easily show (see below) for any differentiable function $f(E)$ that

$$\frac{1}{D} \sum_{\alpha=1}^{D} f(E_\alpha) - \int_{U-\Delta U-\eta}^{U+\eta} dE \, \rho_\eta(E) \, f(E) \leq \eta \times \sup_{E \in [U-\Delta U-\eta, U+\eta]} |f'(E)|,$$

(B.3)

which becomes (2.5) if we set $\eta$ as in (2.6) and denote the corresponding $\rho_\eta(E)$ as $\rho(E)$.

By definition, $\rho_\eta(E)$ is a summation of many functions, each having a width of order $\eta$ and a height of order $1/\eta$. Note that the limit $\rho_0(E)$ is a collection of $\delta$ functions, and exactly describes the discrete distribution of $E_\alpha$’s. The idea is to use an appropriate $\eta > 0$ and get $\rho_\eta(E)$ that can be regarded as a physical density of state, which is smooth and monotone increasing.

If $\eta$ is too small, $\rho_\eta(E)$ still looks like a collection of $\delta$ functions, and is far from monotone. It does not look like a usual density of state, and we can never hope the bound (2.7) to be valid. If $\eta$ is sufficiently larger than the typical spacing of the energy levels, on the other hand, we expect a monotone $\rho_\eta$ which behaves like a density of...
states, and for which (2.7) is justified. Because we have \( D \) levels, we expect to have a well-behaved \( \rho(\eta) \) for \( \eta = D^{-\kappa} \tilde{\beta}^{-1} \) with \( \kappa < 1 \) provided that \( D \gg 1 \). The constant \( \tilde{\beta} \) is introduced so that \( \eta \) has the dimension of energy.

**Proof of (2.5):** Because \( k(x) \) is normalized, we can write
\[
\sum_{\alpha=1}^{D} f(E_\alpha) = \sum_{\alpha=1}^{D} \int dE \frac{1}{\eta} k\left(\frac{E - E_\alpha}{\eta}\right) f(E_\alpha). \tag{B.4}
\]

Therefore, the left hand side of (2.5), multiplied by \( D \), can be written as
\[
\sum_{\alpha=1}^{D} f(E_\alpha) - \int dE \rho(\eta) f(E) = \sum_{\alpha=1}^{D} \int dE \frac{1}{\eta} k\left(\frac{E - E_\alpha}{\eta}\right) \{f(E_\alpha) - f(E)\}. \tag{B.5}
\]

Now by the mean value theorem,
\[
\left| f(E_\alpha) - f(E) \right| \leq |f'(E^*)| \left| E_\alpha - E \right| \leq \tilde{f} \left| E_\alpha - E \right|, \tag{B.6}
\]
where \( E^* \) is a point between \( E_\alpha \) and \( E \), and we introduced \( \tilde{f} := \sup_{U - \Delta U - \eta \leq E \leq U + \eta} |f'(E)| \).

We thus have
\[
\left| \sum_{\alpha=1}^{D} f(E_\alpha) - \int dE \rho(\eta) f(E) \right| \leq \sum_{\alpha=1}^{D} \int dE \frac{1}{\eta} k\left(\frac{E - E_\alpha}{\eta}\right) \tilde{f} \left| E_\alpha - E \right| = D \tilde{f} \int dE \frac{1}{\eta} k\left(\frac{E - E_\alpha}{\eta}\right) \left| E_\alpha - E \right| = D \tilde{f} \int dy k(y) |y| \leq D \tilde{f} \eta, \tag{B.7}
\]
where in the last step we used the fact that the expectation of \( |y| \) with respect to the normalized measure \( dy k(y) \) cannot exceed one.

We wish to thank Hiroyuki Ochiai for his indispensable help in the issues regarding the symmetric group, such as Lemmas A.2 and A.4, and Benoît Collins for discussions about upper bounds on \( |Wg(\sigma)| \), and for informing us of the literature [26]. We also thank Tetsuo Deguchi, Takaaki Monnai, Shin-ichi Sasa, Akira Shimizu, Tomoyuki Shirai, Ayumu Sugita, Sho Sugiuara, and Yu Watanabe for valuable discussions and comments, and Marcus Cramer for bringing our attention to [17].

The present work was supported in part by grant no. 37433 from the John Templeton Foundation (S.G.), JSPS Grants-in-Aid for Scientific Research nos. 25610021 (T.H.) and 25400407 (H.T.).
