Abstract

Asthma is an allergic inflammatory disease of the airways, in which numerous cell types and cytokines have been shown to contribute to pathogenesis of the disease. Although increased expression of IL-9 has been shown to influence the activity of structural as well as eosinophils and mast cells in asthma, the influence of IL-9 on function of ILC2 and Th2 cells remains unclear. This study therefore aimed to elucidate the role of IL-9 on ILC2 and Th2 cells using a murine model of asthma. A murine model of asthma was established using wild type (WT) and IL-9-deficient (Il9−/−) transgenic mice sensitized to house dust mite (HDM). Bronchoalveolar lavage fluid (BALF) and lung tissues were collected, and analysed for inflammatory cells (eosinophils, mast cells, Th2 cells and ILC2 cells), histopathological changes, and several cytokines. HDM challenge significantly increased accumulation of ILC2 cells, Th2 cells and mast cells, as well as goblet cell hyperplasia, and the expression of cytokines IL-4, IL-5 and IL-13, but not IFN-γ, in WT mice compared to saline-challenged control group. In contrast, all pathological changes, including infiltration of ILC2 cells, Th2 cells and mast cells, were significantly attenuated in HDM-challenged Il9−/− mice. Furthermore, the number of Ki67+ILC2 cells, Ki67+Th2 cells and Ki67+mast cells were significantly reduced in the absence of IL-9 signalling. These data suggest that IL-9 promotes the proliferation and type 2 cytokine production of type 2 cells in the murine models of asthma, and therefore might be a potential therapeutic target for asthma treatment.

1. Introduction

Asthma is a common airway inflammatory disease involving cells of both the innate and adaptive immune systems. Currently, approximately 8% of people in developed countries have asthma compared with 4.3% of the population worldwide, and both numbers are on the rise1. Various inflammatory cell types, including T cell, B cell, ILC2 cell, eosinophil, and mast cell, are involved in the complex allergic inflammatory response in the airways2. In particular, Th2 cells and ILC2 cells are thought to play major roles in initiation and maintenance of the allergic inflammation2. Production of cytokines such as IL-4, IL-5, IL-9, and IL-13 by these cells is thought to be involved in the development of asthmatic features, including pulmonary eosinophilia, mucus overproduction, mast cell hyperplasia, and bronchial hyperresponsiveness. However, the precise roles of the triggers and mediators involved in generating these processes remain to be clarified.

IL-9, a pleiotropic cytokine, can promote allergic inflammation and is associated with various pathophysiological changes observed in the airways of asthmatic patients, such as eosinophilic inflammation, mucus gland hyperplasia and hypertrophy, and bronchial hyperresponsiveness3. Consistent with elevated expression of IL-9 in peripheral blood mononuclear cells and lung tissues of asthmatic patients4,5, over-expression of IL-9 results in accumulation of eosinophils, mucus overproduction, and mast cell hyperplasia3,6,7. Furthermore, anti-IL-9 treatment ameliorates airway inflammation in mouse models of asthma employing ovalbumin sensitization and challenge8–11. Moreover, IL-9 promotes mast cell growth in vitro12, while neutralization of IL-9 markedly diminished
mucosal mast cell activation and mast cell numbers in the lung in a mouse model of asthma\textsuperscript{10}. Despite the evidence for the effect of IL-9 on mast cells in asthma, whether IL-9 affects the other effector cells in asthma remains unclear.

Although IL-9 was originally described as a T cell growth factor \textit{in vitro}\textsuperscript{13}, its role on T lymphocyte responses presently remains controversial. Treatment with an anti-IL-9 antibody markedly reduces the number of Th2 cells in a mouse of allergic rhinitis\textsuperscript{14}, however, anti-IL-9 treatment does not affect ovalbumin-induced Th2 cytokine production by mice spleen T cells \textit{in vitro}\textsuperscript{11}. Thus, it is worthy to investigate the mode of action of IL-9 and whether this cytokine acts on ILC2 and Th2 cells in allergic airway inflammation.

In the present study, we have established a murine model of asthma using wild type (WT) and IL-9-deficient (\textit{Il9}\textsuperscript{−/−}) mice and then investigated the distribution of mast cells, Th2 cells and ILC2 cells, following sensitization to and challenge with HDM. Furthermore, the potential role of IL-9 in regulation of these effector cells and allergic inflammation was also investigated.

2. Materials And Methods

2.1 Animals

Female BALB/c mice (8-10 weeks old; Vital River Laboratory, Beijing, China) were kept in a pathogen-free environment in the Department of Laboratory Animal Sciences, Capital Medical University, Beijing, China. \textit{Il9}\textsuperscript{−/−} mice (BALB/c background) were kindly provided by Professor Andrew McKenzie (Medical Research Council Laboratory of Molecular Biology, Cambridge, UK). All animal studies were carried out strictly under protocols approved by the Institutional Animal Care and Use Committee at Capital Medical University, Beijing, China.

2.2 Murine models

Murine surrogates of asthma induced by HDM challenge were prepared and studied as previously described\textsuperscript{15}. Briefly, WT and \textit{Il9}\textsuperscript{−/−} mice were randomly assigned to two groups. The mice in the HDM-challenged group were first sensitized (day 0) by intraperitoneal injection of 100 µg HDM (Cosmo Bio Co LTD), emulsified in AL[OH]\textsubscript{3}/dose. Seven days later, the mice were challenged daily for five consecutive days with 50 µg of HDM in 50 µL saline/dose by intranasal instillation. Mice in the saline control challenge group were injected intraperitoneally with the same amount of AL[OH]\textsubscript{3} and intra-nasally with saline at the same time points corresponding to those in the HDM challenge group (Fig. 1a). The mice were sacrificed 24 hours after the final challenge and bronchoalveolar lavage fluid (BALF) and lung tissues were collected from each animal.

2.3 Lung function measurement
Airways hyperresponsiveness (AHR) was assessed on day 12, 24 hrs after the final intranasal challenge. AHR was determined by measuring changes in lung resistance in anaesthetised, tracheotomised mice in response to increasing concentrations of aerosolised methacholine (Mch) (0–48 mg/mL) using the FlexiVent system (SCIREQ Inc., Montreal, QC, Canada) as described previously\textsuperscript{16,17}.

2.4 Collection of BALF and characterization of cellular infiltrate

BALF was collected from the mice and total cells were enumerated as previously described\textsuperscript{15}. Cellular smears were then prepared and stained with haematoxylin& eosin (H&E) for differential cellular counts\textsuperscript{16}.

2.5 Lung histology

Left lung tissue from each animal was fixed in 4% paraformaldehyde and embedded in paraffin wax prior to cutting into sections (5 µm thickness). The sections were stained with H&E for scoring of inflammatory cellular infiltration under light microscopy by operators ignorant of the provenance of the sections, as previously described\textsuperscript{16,17}. Briefly, the numbers of peribronchial, infiltrating cells were scored globally by eye as 0–5, where 0 = no cells; 1 = a few cells; 2 = at least one layer of peribronchial cells; 3 = 2–4 layers of peribronchial cells; 4 = > 4 layers of peribronchial cells; 5 = abundant proximal and distal cellular infiltration. 6–10 airways were counted per mouse.

Additional sections were stained with periodic acid-Schiff (PAS) for detection of mucus deposition. PAS staining was assessed semi-quantitatively in sections of central and peripheral airways as the mean score of typically 14 central and peripheral airways, where 0 = ≤ 5% goblet cells; 1 = 5–25%; 2 = 25–50%; 3 = 50–75%; 4 = ≥ 75%. Further lung sections were stained with Congo red stain for detection of eosinophil infiltration\textsuperscript{16,17}. Digital photographs of 10 bronchioles per tissue section were taken at × 40 magnification and Image-Pro Plus was used to objectively quantify Congo red stained eosinophils, as previously described\textsuperscript{16,17}.

2.6 Cytokines analysis

Resected right lungs were weighed then homogenised in PBS containing 1% Triton X-100 and protease inhibitor cocktail (RocheDiagnostics GmbH, Mannheim, Germany). After centrifugation to remove debris, the supernatants were collected for measurement of cytokines. The concentrations of IL-4, IL-5, IL-6, IL-13, IL-17A, IL-25, IL-33, IFN-γ, mast cell protease 1 (mMCP-1) and thymic stromal lymphopoietin (TSLP) were measured using commercial ELISA kits (Invitrogen, San Diego, CA). The concentrations of serum total IgE antibody was measured by ELISA (Invitrogen).

2.7 Preparation of single-cell suspensions and flow cytometric analysis

To compare cellular profiles after the induction of airway inflammation, single-cell suspensions were prepared from lungs and BALF cells. The cell suspensions were stained for different cell types using
specific antibodies, prior to assessment by flow cytometry as follows: APC-anti-mouse Lineage cocktail (BD phamingen, San Jose, CA), APC-Cy7-anti-mouse CD45 (30-F11, BD phamingen), BV510-anti-mouse ST2 (U29-93, BD phamingen), PE-anti-mouse ICOS (7E.17G9, BD phamingen), BV650-anti-mouse CD4 (RM4.5, BD phamingen), BUV395-anti-mouse GATA3 (L50-823, BD phamingen), BV711-anti-mouse CD117 (2B8, BD phamingen), Percp-Cy5.5-anti-mouse FcεRIα (MAR-1, Biolegend, San Diego, CA), PE-Cy7-anti-mouse Ki67 (SolA15, eBioscience, Santa Clara, CA). Isotype and single-stain controls were included. The samples were processed using the LSRFortessa (BD Biosciences, San Jose, CA) flow cytometer and evaluated with Flow Jo software (version V10, Tree Star, Inc., Ashland OR).

2.8 Statistical analysis

Data were expressed as the mean ± SD and the unpaired t-test was used to analyse the significance of any differences between the groups. All statistical analyses were performed using Graph Pad Prism software and a value of $P < 0.05$ was considered to be statistically significant.

3. Results

3.1 IL-9 deficiency attenuated HDM-induced airway hypersponsiveness

WT and Il9$^{-/-}$ mice were intranasally challenged with HDM or saline control as described in the Methods (Fig. 1a). Consistent with our previous report$^{15}$, HDM challenge induced a significant elevation of airways resistance compared with saline challenge in WT mice. However, a decrease of airway resistance was noticed in Il9$^{-/-}$ mice compared to WT mice following HDM challenge (Fig. 1b). And there was no significant difference in airway resistance between HDM-challenged Il9$^{-/-}$ mice and saline-challenged Il9$^{-/-}$ mice (Fig. 1b).

3.2 IL-9 deficiency attenuated HDM-induced inflammatory cellular infiltration of the lung parenchyma tissues and airways

Intranasal challenge with HDM resulted in marked infiltration of inflammatory cells into the airway lumen and peribronchial and perivascular regions of the lung tissues, compared with saline control (Fig. 2a, b). Most of the cells infiltrating the lumen were eosinophils, neutrophils and lymphocytes with eosinophils predominating (Fig. 2b). Although HDM challenge also induced inflammatory cellular infiltration into the lungs in the Il9$^{-/-}$ mice, the numbers of infiltrating inflammatory cells were significantly lower in the Il9$^{-/-}$ mice compared with that in the WT mice (Fig. 2b).

3.3 IL-9 deficiency decreased HDM-induced eosinophil infiltration into the airways
Congo red staining confirmed the presence of abundant eosinophils in the airway peribronchial and perivascular regions of the WT mice challenged with HDM compared with control mice challenged with saline (Fig. 3a), and that eosinophilic infiltration in the HDM-challenged $\text{Il9}^{-/-}$ mice was significantly attenuated compared with HDM-challenged WT mice (Fig. 3a).

### 3.4 IL-9 deficiency decreased HDM-induced airway goblet cell hyperplasia

PAS staining demonstrated that HDM inhalation challenge also significantly increased mucous hyperplasia in the bronchial epithelium of WT mice compared to control saline challenge, and that IL-9 deficiency attenuated the HDM-induced goblet cell hyperplasia, as indicated by significantly lower mean PAS score in the $\text{Il9}^{-/-}$ mice compared to WT animals (Fig. 3b).

### 3.5 IL-9 deficiency attenuated HDM-induced production of cytokines in lung homogenates

ELISA analysis of lung homogenates revealed that HDM challenge regimens caused significantly elevated expression of the Th2 cytokines IL-4, IL-5 and IL-13, but not the Th1 cytokine IFN-$\gamma$, in WT and $\text{Il9}^{-/-}$ mice compared with saline-challenge (Fig. 4). Intranasal challenge with HDM also induced a marked increase in the concentration of the inflammatory mediators IL-6, mMCP-1 and IL-17A in both WT and $\text{Il9}^{-/-}$ mice compared with the relevant saline challenge (Fig. 4). Notably, the concentrations of all of these cytokines were significantly decreased in the $\text{Il9}^{-/-}$ mice compared with the WT mice following HDM challenge (Fig. 4), suggesting that IL-9 deficiency in $\text{Il9}^{-/-}$ mice is likely to result in the attenuation of HDM-induced expression of Th2 cytokines. Interestingly, HDM challenge also markedly and significantly elevated the expression of IL-25, IL-33 and TSLP (three cytokines also thought to play a pivotal role in the initiation of asthma) in the lung tissue of both WT and $\text{Il9}^{-/-}$ mice compared with saline challenge. However, the expression of these cytokines was not significantly different in the HDM-challenged $\text{Il9}^{-/-}$ mice and WT mice, indicating that IL-9 deficiency is unlikely to influence the expression of these cytokines (Fig. 4). Albeit, HDM challenge induced a marked increase in the concentrations of total serum IgE in WT mice, it cannot alter the concentration of total serum IgE in the $\text{Il9}^{-/-}$ mice (Fig. 4).

### 3.6 IL-9 deficiency reduced ILC2 cell, Th2 cell, and mast cell accumulation in the lung tissue of HDM-challenged mice

Flow cytometry showed that HDM challenge induced a dramatic increase in the percentages and absolute numbers of ILC2 cells (Fig. 5), Th2 cells (Fig. 6) and mast cells (Fig. 7) in the lung tissues and BALF of both WT and $\text{Il9}^{-/-}$ mice compared to the control saline challenge; and the HDM-induced increases in these infiltrating cells were significantly attenuated in the HDM-challenged $\text{Il9}^{-/-}$ mice compared with the HDM challenged WT animals (Figs. 5b, 6b, 7b). The significantly elevated numbers of
mast cells in the Il9−/−mice challenged with HDM compared with saline control is consistent with the change in the expression of mMCP-1 (Fig. 4).

3.7 IL-9 deficiency inhibited the proliferation of ILC2, Th2 and mast cells

We assessed expression of Ki67 in ILC2, Th2 and mast cells in the lung tissues. As expected, the percentages and mean number of Ki67⁺ILC2 cells (Fig. 5c), Ki67⁺Th2 cells (Fig. 6c), and Ki67⁺mast cells (Fig. 7c) were significantly increased in the lung tissues of the WT mice with HDM challenge in comparison to the saline control challenge. In contrast, depletion of the IL-9 gene significantly attenuated the percentages and total number of Ki67⁺ILC2 cells (Fig. 5c), Ki67⁺Th2 cells (Fig. 6c), and Ki67⁺ mast cells (Fig. 7c) in the lung tissues of the HDM-challenged Il9−/−mice compared with HDM-challenged WT mice.

4. Discussion

IL-9, a pleiotropic cytokine, has been implicated in the pathogenesis of many atopic diseases; including allergic rhinitis, asthma, atopic dermatitis, contact dermatitis, and food allergy; through a variety of activities on mast cells, epithelial cells and smooth muscle cells. Previous studies have addressed the role of IL-9 in inducing changes associated with human asthma by investigating the airways of animals by blockade or genetic knock-down of IL-9 designed to induce allergic inflammation or over expression of IL-9. The present study further explored the role of IL-9 by comparing the differences in airway inflammation and percentages and numbers of target cells (ILC2 cells, Th2 cells and mast cells) in murine asthma models of WT and Il9−/−mice challenged with HDM. It has been well documented that type 2 cytokines IL-5 and IL-13 are implicated in the pathogenesis of the eosinophil-rich airway inflammation, which typically characterizes asthma. In the present study we demonstrated that IL-9 deficiency clearly attenuated the production of type 2 cytokines. This finding is in accordance with a previous study, which showed that IL-9 blockade reduced the concentrations of these mediators in the BALF of OVA-sensitized and challenged mice. Using HDM-challenged murine models of asthma, our data further indicated that IL-9 deficiency reduced proliferation of target cells (ILC2 cells, Th2 cells and mast cells) and infiltration of eosinophils. Furthermore, IL-9 deficiency may also partly account for reduced goblet cell hyperplasia and hypertrophy observed in the present study, particularly as type 2 cytokines and eosinophils have been implicated as contributory factors to these phenomena.

The epithelium-derived cytokines IL-33, TSLP, and IL-25 have been implicated in pathogenesis of asthma because they promote type 2 cytokine synthesis. Correspondingly, our data showed that the expression of these cytokines increased in the HDM-sensitized and challenged mice. Interestingly, IL-9 deficiency did not further reduce the expression of IL-33, IL-25 and TSLP, although the airway infiltration of inflammatory cells, goblet cell hyperplasia, and type 2 cytokines production were attenuated. These observations suggest that IL-9 may be a critical downstream component of IL-33, IL-25 and TSLP.
signaling pathways in asthma pathogenesis. Moreover, these data are consistent with previous studies which have shown that IL-9 was required for allergic airway inflammation mediated by TSLP and IL-9 deficiency attenuated airway inflammation in the IL-33-induced asthma model. These observations might also, partially explain why deletion of the IL-9 gene could not completely abolish HDM-induced airways inflammation.

It has been reported that ILC2 cells are able to produce IL-9, which is crucial for survival of the ILC2 cells. Whilst the numbers of ILC2s in helminth-induced lung inflammation have been shown to be reduced in IL-9 receptor deficient mice, neutralization of IL-9 has not been found to affect the ILC2 numbers in lung tissues in a papain-induced murine model of lung inflammation. However, our data have shown that IL-9 deficiency markedly attenuated ILC2 cell accumulation and production of IL-5 and IL-13, which are consistent with the findings from other studies. For example, IL-9 deficiency in ILC2 cells led to a decrease in IL-5 and IL-13 production in cells cultured in the presence of TSLP and IL-33, despite the number of ILC2 cells not being affected. Taken together, these results suggest that IL-9 may promote allergic inflammation by amplifying the function of ILC2.

With reference to the different Th subsets, it has been shown that IL-9 acts as a growth factor for especially Th2 and Th17 cells. Previous studies have shown that anti-IL-9 antibody treatment was able to inhibit airway inflammation by reducing the number of Th17 cells and IL-17 levels. Additionally, it has been also shown that IL-9 mediates Th17 differentiation in vitro. Furthermore, pulmonary overexpression of IL-9 appears to induce Th2 differentiation leading to pathologic changes in the lungs. Our findings for Th2 cells are also in accordance with these studies, and have further demonstrated that IL-9 deficiency significantly decreased Th2 cells infiltration and production of IL-4, IL-5, IL-13 and IL-17A; suggest that IL-9 can act on Th2 cells and Th17 cells, which are major contributors to allergic inflammation, either directly or indirectly.

Mast cells are a main target of IL-9, which serves as a growth factor for these cells and also influences their function. The present study demonstrated that mast cell accumulation in the lung tissue of HDM-challenged mice was clearly attenuated by IL-9 deficiency, and this was supported by the reduction of mMCP-1 in the lung tissue homogenate of the experimental animals. These findings are in accordance with previous studies, which indicated that accumulation of mast cells in a model of acute allergic inflammation was dependent on IL-9, because neutralizing IL-9 dramatically reduced the number of mast cells infiltrating the lungs. These data suggest that IL-9 inhibition might be required to diminish pulmonary mast cell numbers, possibly providing some beneficial effects in asthmatics.

Our studies have shown that IL-9 deficiency markedly reduced the numbers of ILC2 cells, Th2 cells and mast cells, in BALF and the lung tissues of HDM-challenged mice. Thus, it is reasonable to speculate that IL-9 deficiency might inhibit ILC2 cells, Th2 cells and mast cells accumulation in the lung by leading to decreased proliferation of these cells. Indeed, assessment of the expression of Ki67 in these cells, as a marker for cells that were in active phases of the cell cycle, demonstrated that the number of Ki67+ ILC2
cells, Ki67^+Th2 cells and Ki67^+mast cells in the Il9^−/−mice was clearly reduced compared to that in WT mice following HDM challenge, thus supporting the hypothesis that IL-9 deficiency may partly affect proliferation of ILC2, Th2 and mast cells.

In summary, our study has demonstrated a critical role for IL-9 in regulating numbers of ILC2 cells, Th2 cells, mast cells and expression of cytokines produced by these cells in the airways of HDM sensitized mice, following allergen challenge. Furthermore, IL-9 deficiency results in a profound decrease in inflammatory cellular infiltration and goblet cell hyperplasia. It is possible that IL-9 might promote proliferation of ILC2 cells, Th2 cells and mast cells. These findings should improve the understanding of the pathogenesis of asthma and facilitate the development of novel therapies for treatment of this disease.

**Figures**
IL-9 deficiency decreased HDM-induced airways resistance. (a) Schedule of allergen challenge in mice. (b) Airways resistance (Rrs) of wild type (WT) and IL-9 deficient (Il9−/−) mice challenged with HDM or saline (NS) control. * $p< 0.05$ versus NS challenged wild type mice, # $p< 0.05$ versus Il9−/− mice challenged with HDM. Data are presented as the mean ± SD (n=4-5 in each group).
Figure 2

IL-9 deficiency decreased HDM-induced inflammatory cellular infiltration. (a) Left: representative photomicrographs of haematoxylin & eosin-stained lung sections from WT and Il9−/− mice challenged with HDM and saline (magnification × 10). Right: semi-quantitative scoring of the severity of inflammatory infiltrates in the airways. (c) Numbers of total cells, eosinophils, neutrophils and lymphocytes in bronchoalveolar lavage fluid (BALF) of WT and Il9−/− mice challenged with HDM and NS. Bars show the mean ± SD (n=4-6 in each group). * p< 0.05, ** p< 0.01, *** p< 0.001.

Figure 3

IL-9 deficiency decreased HDM-induced eosinophil infiltration and goblet cell hyperplasia. (a) Left: representative photomicrographs of Congo red-stained sections of lung tissues from WT and Il9−/− mice
challenged with HDM and NS (magnification × 40). Right: numbers of Congo red+ cells per unit area (mm²) (b) Left: representative photomicrographs of PAS-stained sections of lung tissue from WT and Il9−/− mice challenged with HDM and NS (original magnification × 10). Right: mucus score based on PAS staining (see Materials and methods). Bars show the mean ± SD (n=4-6 in each group). * p< 0.05, ** p< 0.01, *** p< 0.001.

Figure 4

Concentrations of cytokines in lung homogenates and serum IgE of WT and Il9−/− mice challenged with HDM and NS. Bars show the mean ± SD (n=4-6 in each group). * p< 0.05, ** p< 0.01, *** p< 0.001.
Figure 5

Flow cytometric analysis of ILC2 cells in lung and BALF. (a) The protocol for gating ILC2 cells (Lin−CD45+ST2+ICOS+). (b) Flow cytometric identification of ILC2 cells in single-cell suspensions of the BAL fluid (BALF) and lung parenchyma (Lung) of WT and Il9−/−mice challenged with HDM and NS. Left: representative plots of ST2+ICOS+ ILC2 cells of indicated mice. Right: the percentages of ILC2 cells in lineage-negative cells from BALF and lung. And total number of ILC2 cells in BALF and lung. (c) Flow cytometric analysis of ILC2 cells expressing Ki67 in lung parenchyma. Left: representative plots of Ki67+ILC2 cells of indicated mice. Right: the percentages and absolute number of Ki67+ILC2 cells in lung parenchyma. Bars show the mean ± SD (n=3-5 in each group). * p< 0.05, ** p< 0.01, *** p< 0.001.
Figure 6

Flow cytometric analysis of Th2 cells in lung and BALF. (a) The protocol for gating Th2 cells (CD4⁺GATA3⁺). (b) Flow cytometric identification of Th2 cells in single-cell suspensions of the BAL fluid (BALF) and lung parenchyma (Lung) of WT and Il9⁻/⁻ mice challenged with HDM and NS. Left: representative plots of CD4⁺GATA3⁺ Th2 cells of indicated mice. Right: the percentages of Th2 cells in lymphocytes from BALF and lung. And total number of Th2 cells in BALF and lung. (c) Flow cytometric analysis of Th2 cells expressing Ki67 in lung parenchyma. Left: representative plots of Ki67⁺Th2 cells of indicated mice. Right: the percentages and absolute number of Ki67⁺Th2 cells in lung parenchyma. Bars show the mean ± SD (n=3-5 in each group). * p< 0.05, ** p< 0.01, *** p< 0.001.
Figure 7

Flow cytometric analysis of mast cells in lung and BALF. (a) The protocol for gating mast cells (CD117\(^+\) FcεRα\(^+\)). (b) Flow cytometric identification of mast cells in single-cell suspensions of the BAL fluid (BALF) and lung parenchyma (Lung) of WT and \(il9^-\)mice challenged with HDM and NS. Left: representative plots of CD117\(^+\) FcεRα\(^+\) mast cells of indicated mice after gating out dead cells. Right: the percentages of mast cells in BALF and lung. And total number of mast cells in BALF and lung. (c) Flow cytometric analysis of mast cells expressing Ki67 in lung parenchyma. Left: representative plots of Ki67\(^+\) mast cells of indicated mice. Right: the percentages and absolute number of Ki67\(^+\) mast cells in lung parenchyma. Bars show the mean ± SD (n=3-5 in each group). * \(p<0.05\), ** \(p<0.01\), *** \(p<0.001\).
